I try to tell every customer who buys a rig not to leave it in his car; far too many come back the very next day to get a serial number for the police (never thought it could happen in a nice town like . . .).

I hope everyone who reads this will try to keep his rig out of harm's way. We need the business, but I sure hate to get it this way. By the way, Wayne, we will keep an eye out for your CB radio along with all the others.

Chuck Martin WA1KPS
Tufts Radio, Medford MA

KENWOOD GROUP

I wonder if I might have the temerity to request that something of interest to the HF bands be included in your mag, which I enjoy reading very much. I have recently formed a TS520 group here in ZL. It is primarily aimed at TS520 owners, with the idea of producing a monthly newsletter containing details of mods, accessories and general interest articles. However, the whole range of the Kenwood products can be included if enough interest is generated.

Anyway, I would be much obliged if you could either publish this letter, or a short notice somewhere in the *73* mag, bringing the attention of any Kenwood owners to the formation of the group, correspondence to be addressed to the address below.

Ancient Aviator

from page 15

sold the line to Eastern Air Transport. Eastern asked me to stay on for two or three months to set up a new passenger ticketing and accounting procedure. This took almost three months, after which I joined Jim Eaton in New York to form an aeronautical consulting firm.

BOSTON AND MAINE AIRWAYS

One of our early jobs was for the Ludingtons in an attempt to interest the Boston and Maine RR in operating an airline over some of their routes. Nick Ludington agreed to back the project if our estimates could show a chance for breaking even or for a small profit. The B&M was interested but was only willing to subsidize the project at 30 cents per mile for each mile flown. Our estimates showed that we had to have a minimum of 35¢. So negotiations broke down. Note: A few months later Vidal, Collins and Earhart made the deal with the B&M and started the B&M Airline @ 30¢ per mile. This grew into Northeast Airlines, which was eventually sold to Eastern Airlines.

MARINE AIRLINES

The next project Jim Eaton and I worked on was an airline between New York and Boston, using amphibian airplanes. We proposed to land in the East River in New York and use a ramp that was already constructed at the Skyport at the foot of Wall Street. In Boston, we'd land at a city-owned South Boston pier or the Boston Airport. Equipment was to be two Sikorsky S-40 38 place amphibians.

We had the S-40s on order, I had passed $5000 under the table to get a pier lease from the city, and we had a public offering of our stock ready to hit the market, when Sikorsky advised us that Pan Am had "exercised an option" on the two S-40s and that no more would be available for eight months. I guess it only took a phone call from the President of the airline we would be competing with to the President of Pan Am to do the trick. This was in October, 1936. While Eaton and I were tearing up those nice new stock certificates of Marine Airlines, a phone call came in from Tommy Hitchcock, a partner in Lehman Bros. He said he had a new proposition that he wanted to see us about. Next month I'll tell you about it.

CONTESTS

from page 14

worked, and exchanges sent and received. Please number each new multiplier as worked. A summary sheet should be included showing your call-sign, name, address, number of QSOs on each band and mode, total number of QSOs, total multiplier (maximum of 58), claimed score, and whether the entry is single or multi-operator.

AWARDS:

Certificates will be awarded to the highest scoring station in each California county, state, province, and country. Second and third place awards may be made where justified. In addition, certificates also will be awarded to the highest scoring mobile station, portable station, multi-single, and multi-multi entries. A certificate will be awarded to the club submitting the highest aggregate score.

ENTRIES:

All entries must be sent to the NCCC, c/o Doug Docherty WA6DQM, 2306 Monserat Ave., Belmont CA 94002, and must be postmarked not later than October 31, 1976. A large, business size SASE is requested with each entry. All comments and suggestions will be appreciated.

FIRST CALL DISTRICT HAM OF THE YEAR AWARD 1976

The Federation of Eastern Massachusetts Amateur Radio Associations is now requesting nominations for the "Ham of the Year" award for 1976. Only amateurs in the first call district are eligible and the amateur selected will be the top "good neighbor" among hams, the one who has performed an outstanding public service.

Anyone may nominate an amateur radio operator for the honor. The winner of the award will be chosen for the amateur activity which brings the greatest benefit to an individual or group and for the amount of ingenuity and personal sacrifice displayed in performing the service.

Nominating letters should include the candidate's name, address, call letters, and a complete description of the service performed. Letters should be sent to the Chairman of the FEMARA Awards Committee, 28 Forest Ave., Swampscott MA 01907.

The winner will be presented with a plaque and a cash award at the ARRL New England Convention, Statler-Hilton Hotel, Boston MA, on September 11, 1976.

WHAT HAVE YOU MISSED?

The back issues of 73 are a gold mine of interesting articles . . . just take a look at what's been covered . . . every possible interest. This is the most important library you can have for hamming.

The supply of these back issues is very limited . . . and when these are gone, that will be it. Don't miss out by procrastinating.

Single issues . . . . $1 each (before 1976)
Ten back issues (your choice) . . . . . $12 postpaid in US.
Twenty-five back issues (your choice) $20 postpaid in US.
Twenty-five back issues (our choice) $10 postpaid in US.

JUNE 63. Surplus Issue. DMQ-2 Beacon Tx on 220, increasing ARC-2 transceiver selectivity, PE-97A pwr supply conversion, BC-348 band-spread, inductance tester, converting BC-230 tx, beginner's rx using BC-453, recvr motor-tuning, transistor cw monitor, BC-442 ant relay conversion, mobile loading coils, increasing Two-er selectivity, TV with the ART-26 tx, TRC-8 rx on 220, ARC-5 hf rx & tx, ARC-3 tx on 2M.

AUG 63. Battery-op 6M stn, diode noise gen, video modulation, magic T-R switch, ant gain, halo mods, cw breakin, VEE beam design, coax losses, RF wattmeter, TX Tube Guide, diode pwr supply, "Lunchbox" squelch, SWR explanation, vertical ant info, info on Windom ant.

OCT 63. WBFM transceiver ideas, HF propagation, cheap fone patch, remote-tuned Yagi, construction hints, ant coupler, $5 Vertical, filament xformer construction, 2M nuvistor converter, Lafayette HE-35 mods, Buyer's Guide to Rx & Tx, product detector, novel Hi-C VFO, radio astronomy, panadaptor "if" converter, compact mike amp.

FEB 64. 2M multichannel exciter, rx design ideas, majic t/r switch, loudspeaker enclosures, 40M 2W tx, look at test equipment, radio grounds, 40M ZL Special ant, neutralization.

MAY 67. Quad Issue: 432 Quad-quad-quad, expanded HF quad, Two el quad, miniquad, 40M quad, quad experiments, half-quad, three el quad, 20M quad, tiltover quad, easy-to-erect quad, Quad Bibliography, FET vfo, tube troubleshooting, HF dummy load, understanding "dB," HF SSB/cw rx, geometric circuit design, GSB-201 transceive, FET converter for 10-20M, hi-pass rx filters.

JULY 67. VE ham radio, VE0 hams, dsb adaptor, home brew tower, transistor design, '39 World's Fair, gnd plane ant, G4ZU beam, SSTV monitor, UHF FET preamps, IC "if" strip, vertical ant, VHF/UHF dipper, tower hints, scope monitoring, operating desk, S-Line crossband, hi-school ham club, Heath HR-10 mods.

OCT 67. HF solid state rx, rugged rotator, designing slug-tuned coils, FET converter, SSTV pix gen, VHF log-periodics, rotatable dipole, gamma-match cap, old-time dxing, modern dxing.

JUNE 68. Surplus Issue: Transformer tricks, BC-1206 rx, APS-13 ATV tx, low voltage dc supply, surplus scopes, FM rig commercial xtal types, Wilcox F-3 rx, restoring old equipment, 75A1 rx mods, TRA-19 on 432, freq counter uses, transceiver pwr supply, uses for cheap tape recorders, Surplus Conversion Bibliography, RT-209 walkie on 2M, ARC-1 guard rx, RTTY tx TU.

JULY 68. Wooden tower construction, tiltover towers, erecting a telephone pole, IC AF osc, "dB" explained, ham club tips (Part 1).

SEPT 68. Mobile vhf, 432 FET preamps, converting TV Tuners, xtal osc stability, parallel-Tee design, moonbounce rhombic, 6M xciter (corrections Jan 69), 6M transceiver (corrections Jan 69), 2M dsb amp, ham club tips (Part 3).

NOV 68. SSB xtal filters, solid state troubleshooting, IC freq counter (many errors & omissions), "cv" transformers, space comm odyssey, pulsar info, thin-wire ants, 40M transistor cw tx/rx, BC-348M double conversion, multifunction tester, copper wire specs, thermistor applications, hi-voltage transistor list, ham club tips (Part 5).

JAN 69. Suppressor compressor, HW-12 on 160, beam tuning, AC voltage control, 2M transistor tx, LC power reducer, spectrum analysis info, 6M transistor rx, operating console, RTTY autostart, calculating osc stability, lo-pwr 40 cw tx, sequential relay switching, sightless operator's bridge, ham club tips (Part 7).

FEB 69. SSTV camera mod for fast-scan, tri-band linear, selective af filter, unijunction transistor info, Nikola Tesla biography, mobile installation hints, extra-class license study (Part 1).

MAR 69. Surplus issue: TCS tx mods, cheap compressor/amp, RXZ calculations, transistor keyer, better balanced modulator, transistor oscillators, using blowers, halfwave feedline info, Surplus Conversion Bibliography, extra license study (Part 2).

APR 69. 2-channel scope amp, rx preamp, Two-er PTT, variable DC load, SWR bridge, 100 kHz marker gene, some transistor specs, SB-610 monitorscope mods, portable 6M AM tx, 2M converter, extra license study (Part 3).

MAY 69. 2M Turnstile, 2M Slot, rx attenuator, generator filter, short VEE, quad tuning, using antennascope, measuring ant gain, phone patch regs, SWR indicator, 160M short verticals, 15M antenna, HF propagation angles, FSK exciter, KW summy load, hi-power linear, extra license study (part 4), all-band curtain array.

JUNE 69. Microwave pwr generation, 6M ssb tx, 432-er tx/rx, 6M converter, 2M 5/8 wave whip, UHF tv tuners, ATV video modulator, UHF FET preamps, RTTY monitorscope, extra license study (part 5), building uhf cavities, mini-VEE for 10-20M, vhf vfo.

JULY 69. AM modulator, SSTV sig gen, 6M kw linear, 432 KW amp, 432-er tx/rx, 6M IC converter, radio-controlled models, RTTY IC TU, audio notch filter, VRC-19 conversion, tube substitution, 2M transistor xciter, extra license study (part 6), hf FET vfo.

AUG 69. FET regen for 3.5 MHz up, FM crystal switching, 5/8 wave vertical, introduction to ICs, RTTY tone gen, good/bad transistor checker, 2M AM tx, measure transistor Ft, 160M propagation, triac applications, simple IF sweep gen, transistor keyer, SB-100 on 6M, xtal freq measurement, extra license study (part 7), FM deviation meter, qrp am 6M tx, circular quads, FM noise figure, transistor parameter tracer.

SEPT 69. Tunnel diode theory, majic tee, soldering techniques, wave travel theory, cable shielding, transistor theory, AM noise limiter, AFSK gen, transistor amp debugging, measure meter resistance, diode-stack pwr supply, transistor testing, 2¼W 6M tx, HX-10 neutralizing, capacitor useage, radio propagation, AM mod percentage, extra class license study (part 8), 3-400Z linear, ATV vidicon camera, 2 transistor testers, FET compressor, rf plate choke.

OCT 69. Super gain 40M ant, FET chirper, telephone info, scope calibrator, thyrector surge protector, slower tuning rates, identify calibrator harmonics, FM adaptor for AM tx, CB sets on 6M, proportional control xtal oven, xtal filter installation, Q-multiplier, transceiver pwr supply, extra class study (part 9).

NOV 69. NCX-3 on 6M, IF notch filters, dial calibration, HW32A external VFO, 6M converter, feedline info, rf z-bridge, fm mobile hints, umbrella ant, 432-er tx (part 1), pwr supply tricks with diodes, transistor keyer, transistor bias design, xtal vhf sign gen, electronic variac, SB33 mods, extra class study (part 10), SB34 linear improvements.

DEC 69. Transistor-diode checker, dummy load/attenuator, tuned filter chokes, bandswitching Swan 250 & TV-2, 88mh selectivity, match exercizes, rtl xtal calibrator, transistor pa design, hv mobile p.s., 1-10 gHz freqmeter, CB rig on 6M, extra license study (part 11), 1970 buyer's guide.

JAN 70. Transceiver accessory unit, bench power supply, SSTV color method, base-tuned center-loaded ant, 6M bandpass filter, extra license study (part 12, rectifier diode useage, facsimile info.

FEB 70. 18-inch 15M dipole, 6M converter, high-density pc board, camper-mobile hints, 2M freq synthesizer, encoding/decoding for repeaters, DX-35 mods, panoramic vhf rx, variable-Z HF mobile mount, extra license study (part 13), linear IC info, qrp 40M tx, IC Q-multiplier.

MAR 70. Gdo applications, charger for drycells, FM freq meter, pc board construction, ham fm standards, cheap rf wattmeter, multifreq fm osc, "IF" system modules (part 1), Six-er mods, gdo dip lite, Motorola 41V conversion, cw monitor, buying surplus logic, SSO-23A sonobuoy conversion, GRC-9 rx/tx conversion, extra class study (part 14), intro to vhf fm.

APR 70. Noise blanker, 2M hotcarrier diode converter, repeater controller, understanding COR repeater, 7/8-wave 2M ant, extra class study (part 15), inexpensive semiconductors, renovating surplus meters, linear amp bias regulator, hi performance if amp & agc system, SSB bfo for shortwave radio, vacuum tube load box, general fm dope & repeater guide, meggering your ant.

MAY 70. Comments on "fm docket" #18803, future of cw, fm-am rx aligner, 5/8 wave verticals, using 2M intelligently, auto burglar alarms, pwr supplies from surplus components, "IF" system modules (part 2), vhf FET preamps, educated "idiot" lites, postage-stamp 6M tx, extra class study (part 16), Bishop (FNL low-band police monitor, mobile cw tx, Wichita auto-patch.

JUNE 70. DDRR ant, vfo circuit, remote SWR indicator, indoor hf vertical, two rx on one antenna, environment & coax loss, 2-el trap verticals, buying surplus, two 40M qrp tx, 21dB 2M beam, extra class study (part 17).

DEC 70. Solid-state vhf exciter, delta-fre control for SSB, 2M transistor FM tx, HW100 offset tuning, "little gate" dipper, 3-500Z hf linear, general class study (part 5), "transi-test" (no good – errors!), transistor p.s. current limiter.

JAN 71. Split fones for dxing, Heath Ten-er mods, cw duty cycle, repeater zero beater, HEP IC projects, 10-15-20M parabolic ideas, lightning protection, IC rx accessory, attic ants, double-balanced mixers, permanent marker tool, ham license study questions.

FEB 71. Metal locator, varactor theory, AFSK unit, SSTV patch box, ATV hints, RTTY tuning indicator, tone encoder/decoder, 220 MHz converter, SSTV magnetic deflection, IC code osc, 6M tx beeper, general class study (part 6), RTTY intro, perf-board terminal, low-ohmmeter.

MAR 71. IC audio filter, IC 6M converter, trap vertical ideas, digi counter info, surplus equipment identification, hf linear, simple fone patch, repeater audio mixer, digi RTTY accessories, coathanger gndplane, general class study (part 7).

APR 71. Intro to fm, noise blanker, repeater problems, Motorola HT mods, microwave repeater linking, digital ID unit, tuneable 2M fm rx/tx, repeater directory, fm marketplace, meter evaluator, varactor modulator, simple sig gen, touchtone hookup, hf preselector, 10M 12W tx.

MAY 71. 75M mobile whip, 2M preamp, transistor amp design, 10M dsb tx, portable fm transceiver directory, audio compressor-clipper, transistor LM freqmeter, 450 MHz link tx, simple af filter, 1-tube 2M transceiver, surplus 2M power amp, general class study (part 8)

JUNE 71. 2M beam experiments, 3 el 2M quad, multi-band dipole patterns, weather balloon vertical, pocket-pager squelch, two-er vfo, tuning mobile whips, transistor pwr supply, capacity decade box, 40M gain ant, general class study (part 9).

JULY 71. IC audio processor, audio sig gen, cw filter, 2M fm osc, 2M collinear vertical, FM supplier directory, Motorola G-strip conversion, transistor beta tester, general class study (part 10).

AUG 71. Ham facsimile (part 1), 500 Watt linear, dimensions for July collinear, 4-tube 80/40 station, vfo digi readout, Jupiter on 15M, general class study (part 11), pink ticket wavemeter.

SEPT 71. Transformerless power supplies, solid state tv camera, IC substitution, two rf watt meters, IC compressor-agc, multichannel HT-200, ham facsimile (part 2), causes of manmade noise, vfo with tracking mixer, general class study (part 12), transistor heat sinking, IC pulse gen, fone-patch isolation, hcd wattmeters.

OCT 71. Emergency repeater cor, transceiver power supply, predicting meteor showers, digi switching, reverse-current battery charger, passive repeaters, earth grounds, audio "tailoring" filters, Swan 350 mods.

NOV 71. 3-el 75M beam, motor-tuned gnd plane, 2M gain vertical, transistor biasing, split-site repeater, fox-hunting, audio filter, transistor/diode tester, xtal tester, 6M kw amp, 10-15-20M quad, transistor pi-net final, ant feedline, communications dbs, 2300 MHz exciter.

AUG 72. SSTV intro, speech processor, fm repeater info, test probe construction, GE progline ac supply, 432 rf testing, preamp compressor, Six-er mods, fone patch, Two-er info, solar info, SCR regulator for HVPS, "ideal" xtal osc, fm rx adaptor, auto theft alarm.

SEPT 72. Plumbicon tv camera, WWVB 60 kHz rx, cigartube sig gen, cw active filter, rf testing at 1296-3500 GHz, balun ant feed, transistor power supply, IC 6M rx, IC fm/am detector (part 2), active filter design (part 3), K2OAW freq counter (part 3), 2M freq synthesizer (part 1).

OCT 72. Corrections for Aug. fm rx adaptor, 2M freq synthesizer (part 2), 6M transistor vfo, nano-ampere meter, time-freq measurement (part 1), active filter design (part 4), repeater timer, extra-class Q&A (part 3), balloon vertical, ID gen, time delay relay, 432 filter ideas, DC-AC inverter, hc-diode converter, rtl decade and nixie driver, plus-minus supply for ICs.

NOV 72. Hf transistor power amps, RTTY selcal, IC trf rx, transistor keyer, emergency power, 220 MHz preamp, double-delta ant, simple converter using modules, hf RF tester, "lumped line" osc, 2M freq synthesizer (part 3), K2OAW counter errata, 2M preamp, extra class Q&A (part 4), hi-Z voltmeter, Nikola Tesla story, vhf swr meter, transistor regen rx, 432 SSB transverter, AC arc welder, intro to computers, hybrid am modulator, HR10 rx mods, 10M transistor am tx, 40M gndplane, IC logic demonstrator, overload protection, if/rf sweep generator, digi freq counter, aural tx tuning.

DEC 72. SSTV scope analyzer, 2M fm rx, tone burst encoder and decoder, universal if amp, autopatch hookup, LM380N info, voltage variable cap info, 2M 18 watt amp, SSB modulation monitor, xtal freq/activity meter, 10A var. dc supply, transmission line uses, radio astronomy, inductance meter, 75 to 20M transverter, LED info, 40M preamp, transistor vfo, 1972 index, 2M preamp.

JAN 73. HT-220 touchtone, 3-el 20M yagi, 50 MHz freq counter, speech processor, 2-tone gen, fm test set, tilt-over tower, 6M converter using modules, tuneable af filter, six band linear, 10M IF tuner, diode noise limiter, cw/ssb agc, HW22a transceiver 40M mod, HAL ID-1 mod.

FEB 73. CW id gen, tone operated relay, toroidal quadrature ant, active filter, time freq measurement (part 2), repeater timing control, SSTV circuits (part 1), 2M converter using modules, multifunction metering, FET biasing, freq counter preamp, TR22 hi-power mod, transistor rf power amps (part 1), light bulb rf power indicators, 75A4 filters, capacitance measurement, Gonset 201 mod, world time info.

APR 73. FM deviation meter, 2M FET preamp, two 2M power amps, repeater control (part 1), repeater licensing, European 2M fm, fm scanner adaptor, RCA CMU15 mods, lightning detector, cb alignment gadget, transistor rf power amps (part 2), repeater economics.

JUNE 73. 220 MHz sig gen, uhf power meter, repeater licensing info, RTTY autoswitch, 40M hybrid vfo tx, ant polar mount, 10-15-20M quad, K2OAW counter mods, double coax ant, ham summer job, tone decoder, field strength meter, nicad battery pack, ohm meter, FCC regs (part 1).

AUG 73. Log-periodics (part 1), tone burst gen, rf power amp design, transistor radio intercom, 160M ant, SSTV monitor, low cost freq counter, VOM design, qrp 40M tx, 432 MHz exciter, fm audio processing, FCC regs (part 3).

SEPT 73. Repeater control system, log-periodics (part 2), 2M rx calibrator, PLL ic applications, TT pad hookup, Heath HW7 "s" meter, Oscar-6 doppler, 2M coaxial ant, 2M converter, IC keyer, measure ant Z, FCC regs (part 4).

OCT 73. GE Pocketmate mods, microwave freq measurement, CA3102E 2M frontend, 2 kw hf linear, rf wattmeter, meter repair, 60/40 dipole, IC "hi" gen, vhf freq multiplier, FCC regs (part 5).

NOV 73. 450 MHz exciter, intro to ATV circuits, nicad voltage monitor, autopatch connections, IC meter amplifier, TR22 ac supply, indoor vertical, IC af filter, momentary power failure protection, 160M ant acoupler, Motorola HT info, SSTV ISB, Class-B af amp, FCC regs (part 6).

OEC 73. Code speed display, 2M kw amp, IC keyer, 8038 waveform gen, helical resonator design, sensitive rf voltmeter, proximity control switch, IC tester, sequential tone decoder, 2M portable beam, electronic calculator math, cw filter design, FCC regs (part 7).

FEB 74. SSTV monitor info, IC audio amps, scope sweep gen, 15/20M vertical, telephone line control system, pc board construction, var-Q af filter, blown-fuse indicator, 40m cw stn with Ten-Tec modules, simple preamp compressor, single-IC rx, "432-er" final assembly, transistor keying circuit, 7 segment readout with nixie driver.

APR 74. Vox for repeaters, tone-operated relay, hf transverter, 10-to-2m tx converter, remote control panel for scanner, RCA fm tx tuning, subaudible tone gen, FCC regs (part 9), Repeater Atlas.

MAY 74. Cd car ignition, audio compressor info, interference suppression for boats, auto burglar alarms, 2m ic preamp, 10m fet converter.

JULY 74. 4-1000A linear, universal freq gen, universal afsk gen, 555 IC timer, 80M phased array, 135 kHz-432 MHz preamps, 10M qrp am tx, 3000 vdc supply, how to read diagrams.

AUG 74. Toroidal directional wattmeters, 450 MHz FET preamp, use gdo to find "c", Trimline tt pad hookup, R390 & R392 rx mods, tracking cw filter, aural voltmeter, universal regulated supply, sstv scan converter, rtl logic problems, ID timer.

SEPT 74. MOSKEY electronic keyer (part 1), ex warning system, Heath 10-103 scope mods, qrp 6M am tx, rf speech clipper, audio noise limiter, wx satellite on SSTV monitor, universal IC tester, miniature rig construction, tower construction, infinite rf attenuator, electronic

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

WAYNE ON WARCC

You've probably heard about the preparations which are being made for the coming ITU conference. Committees are already at work on proposals for more ham bands . . . etc.

You probably haven't heard a lot about what happened at the last ITU meeting when amateur radio lost virtually all (99.8%) of its satellite bands. That was when the biggest part of the future of amateur radio went down the tubes. Just imagine what we could do with amateur satellites using the 1215-1300 MHz band . . . the 2300-2450 MHz band . . . and all the other bands above two meters! Amateurs anywhere in the world could have talked with any other just as we do via two meter repeaters. All that is no longer possible . . . and never will be possible, for those bands are gone and cannot ever be regained.

Now why were those satellite bands lost? You probably know the answer as well as I do . . . they were lost because we did not make adequate preparations for the conference. Have we learned from this? Possibly . . . but I have not yet seen *any* sign of it.

Before I lay more on you, let me cite my qualifications briefly. Firstly, I was one of the official delegates to the last ITU plenipotentiary conference in 1959, so I have a fair idea of how the ITU works and how the delegates from various countries interact. Since then I have made it a point to visit quite a few countries and talk with the heads of telecommunications. I'm up to 86 countries visited so far. All of this has given me a fair idea of how the world fits together as far as amateur radio is concerned.

Okay . . . if we really want to protect amateur radio and come out of the next ITU conference without more tragic losses, what do we have to do? We only have to look at the report on the satellite frequency losses to get a strong clue . . . and it was exactly what I have recommended in my editorials in the past . . . we need a ham with a good deal of background and the ability to speak well to visit foreign countries and do two major things. Firstly, he should find out what emotional blocks there are against amateur radio . . . and what, if anything, he or U.S. amateurs can do to counter these blocks. It may be that one of our DXpeditioners has left his mark there. Some of them visited countries and promised all sorts of things . . . propagation studies . . . medical help . . . tourists . . . etc. Some told just about any lie they could to get a license and permission to operate for a few days. Things like this may take a lot of ingenuity to overcome.

Other countries are still furious over U.S. amateurs who have been permitted to operate and who ignored the local rules. Some made phone patches home even though they knew they were forbidden . . . others ran illegal high power . . . etc. It was unresolved problems like this that shot us down the last time.

The other thing we can do is make sure that every country in the world understands the immense value of amateur radio to them. This is a story that I've written too many times, so I won't rehash it here. There is hardly a greater gift we can offer a small country than a healthy amateur radio group.

Once some sort of rapport has been established with the telecommunications leader of a country we then will have an opportunity to point out the benefits to the country of backing amateur radio at the ITU. We will also have an opportunity to discuss any position the country may already be considering with regard to frequencies now amateur or proposed for amateurs . . . and we might be able to come up with good alternates and a list of benefits to them for going the alternate routes. *This* is preparation for a conference.

Sitting in on committee meetings in Washington is important too, for if you don't have the U.S. behind you, you're in a poor spot. But the U.S. has one vote . . . and so have each of the African and Asian countries . . . and *these* are the countries that are now running the ITU.

What are our WARCC people doing? Little has been said. What are they planning? Even less has been said about that. I have a feeling that the ARRL will come up with some vague appeal for funds to be donated to either them or a front organization . . . but will these be used for anything positive — or will they be wasted on fun trips for ARRL officials as in the past? A few of us remember that $100,000 fund which was set up for the protection of amateur bands many years ago . . . and we also remember that no accounting to the members has been made of the expenditures from this fund. My own questions about those mysterious expenditures have gone unanswered . . . except in undercover calls from ARRL Directors who knew what had been going on, but were afraid to say anything in public. Yes, we have our own little Watergates, right here in amateur radio. Perhaps it is time for the ARRL to come clean on these things and set up their books so such things can't happen again.

SUPER SPEED CW

A small group of amateurs have been loafing along in the 80-100 wpm range with CW. You may be able to hear them chirping away if you check 7035 and 14035 kHz evenings. They're using codetyping keyboards for sending and copying in their heads.

Yes, I know that the record was set in the '40s by Ted McElroy at 73 wpm, but that was hard copy. As a matter of fact, I used to watch Ted at hamfests demonstrating his skill — it was amazing to behold. The sound was almost like a continuous tone. Ted would start up his code recording and let it play for a bit, talking genially with watching amateurs, then he would sit down at his typewriter and flay away at it, catching up with what had already been sent, continuing his joking with the watchers as he typed.

With a little practice you can join the gang . . . maybe that will take a lot of practice.

One of the benefits of high speed CW vs. RTTY is that full break-in is normally used. It makes it a lot more like talking. A make-break RTTY system could be evolved which would permit this, but as far as I know it hasn't been done yet. There are enough benefits to frequency shift keying, so RTTYers are not likely to chuck it. Amateurs using microprocessors to generate CW could have a

visiting views from around the globe

Lila Howard WA2JIO, receiving a message from Mr. Smith, the harbormaster at Oyster Bay, for transmission to one of the patrol craft.

Larry Stanecker WA2OLP, on the bridge of the Pajo II receiving messages from W2VL during the bicentennial celebration.

Tall Ships Are Tall Order

Friday, July 2, 1976, a day like most other days. Yet a day that would go down in history as one of the major events in a great nation's birthday party. It would also be a day where the abilities of the radio amateur to provide public service would be tested and found more than equal to the task.

The place? Oyster Bay, Nassau County, L.I., N.Y.

The cast? Thousands of visitors and tourists, hundreds of small boats, and six "Tall Ships."

The Mission? To provide radio communications for the harbor patrol, V.I.P. launches, harbormaster's office, and anyone else who needed to get a message from here to there.

The communications team? Dedicated members of the Long Island Mobile Amateur Radio Club (LIMARC)

Prior to the events of this day, the authorities at Oyster Bay, along with others involved in the upcoming "OPSAIL," were fully aware of the problems that could be created by this massive influx of people, boats, and planes, and the varied and sundry things that could be expected as an offshoot of the massive overcrowding of this relatively small area. Conferences were held between the port authorities and Duke Harrison K2OPF, and a game plan was set up wherein LIMARC would provide backup radio communications for all port operations. We were soon to find that "backup" communications can quickly become "primary" communications. The basic plan provided for a base station, located at the harbormaster's office, operating on 146.94/34 in the basic configuration of a repeater. Hand-held units operated by LIMARC members would be scattered about and located on the two V.I.P. docks, aboard the volunteer launches, and aboard the harbor patrol craft normally stationed in Oyster Bay Harbor. Police boats would rely on their own communications gear. Operations would commence at twelve noon on the second and end at midnight. Arrangements were also made with the Port Chester, N.Y., repeater group to keep their 34/94 machine off the air during this period. This was the only machine

that could cause local interference to the LIMARC operations, other than local operators using 94 direct.

Under the direction of K2LIO, a Station Master antenna was set up atop the harbormaster's office and two rigs were installed at a table on the shady side of the building. Commencing at twelve noon, W2VL (the LIMARC commemorative station) went on the air as the Oyster Bay command post station. Skillfully controlled by Lila WA2JIO, who was assisted by over twenty LIMARC members, the station began operating in earnest.

At first there was little to do – and then the deluge began. It appeared that the use of VHF marine radios in the harbor by the myriad small boats, all shouting at once, had rendered these channels totally useless.

CB radios located in the dockside office were also quickly jammed into a morass of 10-4s, 10-36s, 10-20s and Spaceman this is Beetle Buster. Our role as backup communications system had suddenly become that of being the only communications available. With consummate skill, Lila fielded the many calls coming from the launches and quickly set up an ordered net style pattern. With mounting rapidity, the messages came thick and fast: "Ice needed on the *Urania*" (her refrigeration had broken down); "Three crewmen from the *Magic Venture* to go ashore"; "There is a traffic jam of small boats near the Dutch ship *Eendracht*"; "Three V.I.P.s for a harbor tour at the northwest dock"; "Where is the captain of the *Urania*?" As these messages were coming in, the harbormaster had a constant flow of outgoing traffic for the patrol craft, the launches and the operators stationed at the docks. LIMARC members were riding around in Boston Whalers labeled "Harbor Patrol," luxury 28-32 foot skiffs, Bay constable cruisers, and anything else that could float. Out of this chaos came order and an orderly flow of traffic.

As a message handling exercise, it went off with textbook smoothness and great efficiency. As an example of amateur radio at work serving the public, there was no way that it could have been found wanting.

Without it, Oyster Bay harbor would have been a disordered maelstrom of boats, people and electronic noise.

It was best summed up by a harbor patrolman going off duty, who was asked by his replacement how the radios were working. "Well," he said, "the marine radio is no good and the CB is useless, but don't worry, the hams are here."

Weisbaden Riding High

Having been together for more than a year, the Wiesbaden Amateur Radio Club from Wiesbaden, Germany, decided to do something different for a change. Having the usual club activities in high gear, we were in need of another unique activity to push new blood into this already solid and growing club. What better way than to go on a *DXpedition!*

The Wiesbaden Amateur Radio Club was formed over a year ago. It is comprised primarily of U.S. Air Force and U.S. Army personnel stationed in West Germany, along with several American, French, and German civilians. The club has a solid foundation, and although quite new at being a club, has successfully sponsored two hamfests among its other normal club activities. Perhaps it's the lure of adventure or perhaps it's the traveling blood in so many of us overseas, but we decided to partake of the excitement of being DX.

In order to get our feet wet in this new adventure, we arranged for a practice trip to the closest country available for a DXpedition – Luxembourg. The 3 hour drive to LX-land was a worthwhile trip, because we were able to learn many things pertaining to a DXpedition. Our U.S. Field Day experience sure came in handy, and we were then ready to embark to our primary target – Liechtenstein.

Gathering camping equipment, food, personnel, and radio equipment, the first group arrived for our weeklong activity on May 24. The station was set up in a campground near Triesen with a beautiful view of the Swiss Alps to the West. A 50 meter endfed Hertz antenna was strung from one tent to a convenient tree with the aid of the campground owner, who proved to be quite intrigued with our intentions. Then our pride and joy was raised – a 2 element triband quad beamed stateside on top of a 10 meter high portable mast. The campground owner seemed a little hesitant at helping with the quad. Perhaps the awesome size of the antenna proved to be a bit too much for his imagination. We all had our moments of wonder as to whether that beast would ever get off the ground, but we managed to get it flying just before dusk. And, not to let an opportunity slip away to do some serious VHF DXing from such a beautiful mountainside QTH, we erected a 32 element long yagi for 2 meters between a power pole and the quad mast. The rope boom was a cool 25 meters long.

Having the antenna farm in place, we busied ourselves with the equipment. Two HF stations were set up – an SB-102 and SB-200 combination and an HW-101 and SB-200 setup. For VHF we had a Multi-2000 and home brew 200 Watt amplifier for FM and SSB.

Throughout the week we enjoyed many exciting hours of operation. Many local Swiss and Austrian hams came to visit our location. One fellow even brought us a 430 MHz station including the antenna. With that we enjoyed working many stations in Switzerland, Germany, and Austria, thus making our band coverage complete from 3.5 through 430 MHz. We even attempted some Oscar work, but couldn't seem to hook up with the satellite. Next time we'll be ready for Oscar.

We managed to contact 3000 stations throughout the week. We were a little disappointed not to work more Stateside stations, but conditions weren't the best that week. Our VHF operation also proved exciting, as we were able to work stations as far away as Belgium on 2 meters. On several occasions we rolled up the 2 meter long yagi and went to the mountaintop for some truly magnificent VHF mountaintopping.

With the week rapidly drawing to a close, we dismantled HBØXAA to embark on our 8 hour journey northward to Wiesbaden. It was good to get back to a real bed and real food, but what an exciting time being on the other end of DX! We thoroughly enjoyed the operation and found almost all operators to be courteous, thereby enabling us to work many stations with a minimum of QRM.

What's in store next for the Wiesbaden Amateur Radio Club? We have a solid core of DX blood in the group and we are now deciding which DX spot to invade next. There will undoubtedly be a trip in late September to another rare QTH here in Europe. The Weisbaden Amateur Radio Club will ride again. We hope to hear you.

Here We Go Again

I told you last month about how, after years of hard work, Marine Airlines was quickly extinguished when the planes they were planning to use were "pulled out from under them." I also mentioned that Tommy Hitchcock, a partner in Lehman Brothers (bankers), had a situation he wanted to talk to Jim Eaton and myself about. Well, believe me, we wasted no time in getting over to Lehman Brothers to see what he had in mind.

It seems that Lehman Brothers had the controlling interest in the American Export Line, which operated steamships from New York to Mediterranean and Black Sea ports. In addition to some twenty-odd freighters, they operated four combination passenger and freight ships on a scheduled biweekly service to the more important ports. They called the latter the "Four Aces." Hitchcock's idea was that Export, with its well-established routes and connections with the countries touching on the Mediterranean, would be a fine vehicle with which to start and operate a transatlantic airline. Now, Tommy Hitchcock, as you may remember, was a top-notch polo player. One of his principal adversaries on the polo field was "Sonny" Whitney. Sonny was on the Pan American Airways board of directors. Although nothing was ever said on the subject, I have always thought that Hitchcock's enthusiasm with the American Export idea was partially due to his desire to have a go at Whitney in the airline business as well as on the polo field. Hitchcock himself was a good pilot, and owned and flew his own plane.

Talks with Hitchcock started about the first of November, 1936, and then gravitated to officials of American Export, William Coverdale, President, and John Slater, Vice President. Both were associated with the well-known New York engineering firm of Coverdale and Colpitts. All agreed that the days of volume transatlantic passenger transportation by boat were numbered, and, also, that although the "state of the art" had not yet produced aircraft capable of carrying an adequate payload over the transatlantic distances, it would not be too long before such equipment would be available. Export wanted to protect the passenger and light freight traffic on its Mediterranean routes by originating its own airline service. At that time, most American steamship companies were heavily subsidized by the federal government. Each had its own routes laid out by the Federal Maritime Commission. The U.S. Lines, for example, couldn't send ships into Mediterranean ports, and Export couldn't go to Cherbourg, Southampton or North Sea ports. So all their thinking was along the lines of their maritime routes.

Export intended to initiate its service by carrying passengers on the "Four Aces" between New York and the Azores (possibly Horta on Faial), and then to transport them on to the continent and Mediterranean destinations in large flying boats. The equipment for this service could be available in less than a year. The use of flying boats on the initial phase of the operation was made necessary because of the lack of adequate land planes and land plane airports in the Azores and around the Mediterranean. We all knew that, since there was very little difference in safety between flying boats and land planes when it came to a forced landing at sea, land planes would most likely be the ultimate vehicle for over-ocean travel.

Pan American Airways had been largely responsible for pushing American flying boat development. By mid-1936 they, and their associated air carriers, were operating scheduled services from Miami all through the Caribbean islands and around South America. They also flew from San Francisco to Hawaii and on to Manila. In addition, they operated routes in China and Alaska. For over-water routes they used Sikorsky S-42 and S-40 flying boats (32-39 seats) and Sikorsky S-38 and S-41 amphibians (7-22 seats); Ford tri-motors and Lockheed and Fairchild land planes were used in Alaska and over land.

At that time, the U.S. domestic airlines were flying Ford (tin geese), Fokker and Boeing trimotors. The new Douglas DC2 was just coming into use. All snails compared to the present-day jets. Douglas was working on the DC-3 for TWA and Boeing was starting on the development of its 314 flying boats for Pan Am. It took WW2 to speed up development of the four engine DC-4. These planes could make it across the North Atlantic to Northern Ireland by refueling at Gander (Newfoundland) and Reykjavik (Iceland).

Pan Am's ambition was to be the U.S. "chosen instrument" in international air commerce worldwide. They already had plans and equipment being designed for an around-the-world service. Quite an antagonist for American Export to take on. A few years later, after extended and bitterly contested hearings, the Civil Aeronautics Board perversely awarded Pan Am the routes sought by Export and gave Export the northerly route to England, Holland and the Scandinavian countries. More on this later.

My mission on this trip was to check on the availability of adequate flying boat facilities on American Export's route. I was instructed to confer only with Export and U.S. consular personnel and not with government or airline officials of any of the countries involved. Strictly tourist on the surface, camera and all.

After a couple of weeks discussion and briefing in New York, and before we quite realized what had happened, Eaton and I were scheduled to depart on November 24th on the *SS Excalibur* (flag ship of the "Four Aces") for a Mediterranean survey trip. Between conferences with the American Export people and putting Marine Airlines to bed, we had a very short time to update wardrobes, get shots, passports and visas.

Come sailing day, Cleo (my wife), my baggage and I arrived at Pier F, Jersey City, only to find that the poor downtrodden engine department was on strike for some nebulous reason. So we hauled everything back to Brooklyn. Evidently the deck and steward's departments didn't think the engineers had much of a beef, because on December 2nd the *Excalibur* finally set sail as a cargo-only vessel. Eaton and I were signed on as supercargoes. The Engine Department was made up of personnel on loan from various oil companies' ships. The Chief Engineer was fresh off a tugboat in Boston harbor. Since Eaton and I were the only passengers aboard, we were assigned the best cabins and got lots of service.

Everything went fine, good weather, etc., until the fifth day out. Then we started to get salt water in our showers and basins. Due to the engine crew's unfamiliarity with all the various valves, etc., most of our fresh water had been pumped overboard and the tanks filled with sea water. This resulted in corroding quite a few boiler tubes and causing leaks that put one boiler out of commission entirely. So they had to heave to, put out a sea anchor and spend two days replacing boiler tubes. This was no easy task, as only two of the borrowed engine crew were small enough to be able to crawl into the boilers to make repairs. We limped into Ponta Delgada and, after a couple of days of boiler refitting, we took on a supply of fresh water and sailed for Marseilles. I took advantage of the Ponta Delgada stop to go ashore and have a talk with our consul about our proposed operation. I could see that the Ponta Delgada harbor was not large or protected enough for our operation, so the consul suggested the Horta harbor on the island of Faial and furnished me with a detailed map of the islands.

When the *Excalibur* docked at Marseilles, Jim Eaton and I were taken before the U.S. consul, discharged from our supercargo duties and paid $1 each for our services. That was December 14th.

Budd & Co., the Export agents at Marseilles, got Eaton and I rail tickets to Nice for that afternoon. We stayed the night in Nice then went on to Genoa the next day. John Gehan, Export's Mediterranean V.P., met us at the station and settled us in at the Grand Miramare Hotel. This hotel was situated high on the hilly part of Genoa and had an excellent view of downtown Genoa and the harbor. The Miramare was a beautiful old hotel. It was built before the modern concept that every cubic foot must bring in its

CONTESTS

Editor:
Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

Please note the change in my mailing address and callsign. I'm now permanently located in southern New Jersey at the address shown above. All contest material should be sent to that address, preferably at least three months before the scheduled event. We will also continue to list results received as space permits.

1976 RTTY ART CONTEST
Starts: October 1
Ends: November 30

All worldwide licensed radio amateurs and members of their immediate families are eligible to participate in this contest. Each entry must be originated by means of manual inputs to a teleprinter using a standard communications keyboard, and may be submitted only by the originator of the art, or by the amateur on behalf of a family member. Submitted art may be of any subject suitable for transmission via amateur radio, but preference will be given to bicentennial subjects. Entrants may submit any number of entries, but each entry must be given a short title. Tapes of entries shall be formatted to permit a reasonably short running time, and to be compatible with machines which do and do not downshift on space. Compatibility with machines that do not interchange the bell and apostrophe is not required. At least 3 functions must be used between each line (normally CR, LF, and LTRS). Each line of the art shall be limited to 72 characters maximum (including spaces), but overline shading is permitted. Prints must be in one single part with no splices. Tapes must be limited to a maximum running time of 40 minutes at 60 wpm for the art itself, exclusive of any other information on the tape. Each entry must have been transmitted for the first time via amateur radio after October 1, 1976, and must be accompanied by a confirmation of at least one receipt of its transmission, identifying the title of the art and the call letters of the receiving and transmitting stations. All confirmations must be in writing (not by RTTY transmission), and must have been obtained by the entrant from the receiving station. Entrants may obtain necessary transmission of their entry by any amateur radio station. The tape and prints of each entry shall carry the full name of the author, call letters of the submitting station, and mailing address. This information shall be both written upon a beginning leader of the tape and also punched in the tape to appear on the page copy when reproduced. Entrants must submit one 5-level paper tape and five prints of each entry, and by such submission agree that the tapes and prints may be used, duplicated, and published for any purpose. Tape, prints, and transmission confirmation information should be securely packaged and sent to: RTTY Art Contest, c/o Don Royer WA6PIR, 18765 Santa Isadora St., Fountain Valley CA 92708. Entries must be postmarked on or before November 30, 1976. Entries will not be acknowledged or returned. Winners will be announced as soon as possible after the closing date. It is suggested that paper tapes be wound tightly upon a hard core to prevent mail damage!

Entries will be judged on the originality of the author in selection of subject matter, on excellence of technique in producing the art and formatting the tape, on overall appearance of the art when viewed from a distance, on suitability for publication, and on the entrant's compliance with the rules. A committee of judges, made up from those amateurs who have exhibited an interest in RTTY art, will select 1st, 2nd, and 3rd places, as well as honorable mention winners. Winning entrants will receive a plaque for 1st place and certificates for 2nd, 3rd, and honorable mention. Winning entries will be published in the *RTTY Journal* and other amateur radio magazines. The decisions of the judges will be final.

CARTG WORLDWIDE RTTY DX CONTEST
Starts: 0200 GMT Saturday, October 2
Ends: 0200 GMT Monday, October 4

Not more than 30 hours of operation are permitted. Non-operating periods can be taken at any time during the contest, but a summary of times on/off must be submitted with scores. Use all amateur bands, 80 to 10 meters. The ARRL country list will be used for country status, with KL7, KH6, and VO being considered separate countries. Classifications include: single operator (single transmitter), multi-operator (single transmitter), and SWL printer. Individual operators of multi-operator stations may submit their logs singly instead of in the form of a group log.

EXCHANGE:

Message number, time in GMT, and zone.

SCORING:

All two-way RTTY QSOs with own zone count 2 points. All others will receive points listed in Zone Chart (same as last year's chart). Stations may not be contacted more than once on any band. Multipliers are number of different countries worked on each band including one's own country. Each US and Canadian district will be considered as a separate country. Final score is total QSO points times number of countries worked, times number of continents worked (6 maximum). A Canadian Bonus Point is added last — 100 points for each VE/VO contact on all bands.

ENTRIES:

Use separate log sheets for each band. Log sheets and zone charts are available for SASE or IRCs. Logs must be received before December 1st to qualify. Send logs, summary, and scores to: Canadian Amateur Radio Teletype Group, 85 Fifeshire Road, Willowdale, Ontario CANADA M2L 2G9. Many various plaques, medallions and certificates will be awarded!

Feb 19 - 20	YLRL YL-OM Contest — Phone
Mar 5 - 6	YLRL YL-OM Contest — CW

RESULTS

RESULTS OF THE 1975 MARTS SEANET WORLDWIDE DX CONTEST

Seanet Area Top Scorers —
Single band, single operator, Phone: 9VØSN — 188,421 points
Multi-band, single operator, Phone: 9VØSH — 530,784 points
Single band, single operator, CW: VS5PM — 14,418 points
Multi-band, single operator, CW: 9M2LN — 153,537 points

Outside Seanet Area Top Scorers —
Single band, single operator, Phone: LU2AFH — 4,293 points
Multi-band, single operator, Phone: IT9FKS — 5,400 points
Single band, single operator, CW: OH1QB — 609 points
Multi-band, single operator, CW: YZ4HA — 1,386 points

teurs to participate in the 1976 contest.

EXCHANGE:

RS(T) and consecutive serial number starting with 001.

SCORING:

For Oceania stations other than VK/ZL – score 2 points for each VK/ZL QSO on each band, 1 point for each QSO with the rest of the world on each band. For the rest of the world other than VK/ZL – score 2 points for each VK/ZL QSO and 1 point for each Oceania station QSO (other than VK/ZL) on each band. Final score is total QSO points multiplied by the sum of VK/ZL call areas worked on all bands. The same VK/ZL call area worked on different bands counts as separate multipliers!

AWARDS:

Attractive certificates will be awarded to each country (call area in USA, Japan, and USSR) on the following basis:

– Top scorer using all bands;
– Separate awards for phone and CW;
– Other certificates awarded depending on activity: 2nd, 3rd, and separate band awards.

ENTRIES:

Logs must show, in this order: date/time in GMT, callsign of station contacted, band, serial number sent and received. Underline each new VK/ZL call area contacted and make separate logs for each band used. Include a summary sheet showing callsign, name and address (block letters, please), details of equipment used, QSO points for each band, and total VK/ZL call areas worked on that band. Sign a declaration that all rules and regulations have been observed. All logs should be posted to be received before January 31, 1977. Send entries to: NZART Contest Manager, Box 489, Wellington, New Zealand, or NZART Contest Manager, 152 Lytton Road, Gisborne, New Zealand. Every log, even for only a few contacts, would be appreciated.

LISTENERS' SECTION:

A VK or ZL station only must be heard in QSO and the following details noted in the log – date/time in GMT, call of station heard (VK/ZL), callsign of station he is working, RS(T) of VK/ZL station heard, serial number sent by VK/ZL station, band, points. Scoring is on the same basis and the summary sheet should be included.

RSGB 21-28 MHZ CONTEST – PHONE
Contest period:
0700 to 1900 GMT,
October 10

Official rules were not received from England in time for this issue. However, last year's rules were as follows:

Work any British Isle station (G, GC, GD, GI, GM, GW) on 21 and 28 MHz only. The same station may be worked once on each band for QSO and multiplier credit. Use a separate log for each band. Entries are limited to single operators only.

EXCHANGE:

RS and progressive QSO number starting with 001.

SCORING:

Each QSO with a British Isle station counts 3 points. Multiply total QSO points from both bands by the sum of British Isle prefixes worked on each band for final score (GB does not count, giving a maximum of 36 prefixes on each band).

ENTRIES:

Logs should be sent to: D. J. Andrews G3MXJ, 18 Downsview Crescent, Uckfield, Sussex, ENGLAND.

WADM CONTEST
Starts: 1500 GMT Saturday,
October 16
Ends: 1500 GMT Sunday,
October 17

Use all bands between 80 and 10 meters on CW only. Stations outside DM call "CQ DM," while DM stations will call "CQ WADM."

EXCHANGE:

Stations outside DM send usual 6 digit number, RST and serial number starting with 001. DM stations will send a 5 digit number consisting of the RST and the number of their Kreiskenner.

SCORING:

Each station may be worked only once per band. Each completed QSO with a DM station counts 3 points, while incomplete QSOs or QSOs with log errors count 1 point. The multiplier is the total number of DM districts per band. The special stations (DM7, DM8 and DMØ) count for any missing district on the band on which they are worked. The maximum multiplier is 75. The DM districts are the last letter of the callsign (A through O). The final score is the sum of QSO points from all bands multiplied by the final multiplier.

ENTRIES:

Classifications: Single op stations all bands, multi-op stations all bands, and SWLs. Please use separate log sheets for each band and enclose a summary sheet showing the scoring and address. Logs must be sent not later than 30 days after the end of the contest period (postmarked) to: Radioclub of the GDR, DM Contest Manager DM2ATL, DDR 1055 Berlin, P.O. Box 30, German Democratic Republic. The decisions of the DM Contest Bureau are final and the right to change these rules is reserved.

AWARDS:

Certificates will be awarded. Applications for all DM awards (WADM, DMCA, DMDXC, DMKK) may be sent together with logs for the contest, but please use separate sheets for each award.

RSGB 7 MHZ CONTEST – CW
Starts: 1800 GMT Saturday,
October 16
Ends: 1800 GMT Sunday,
October 17

Again, official rules for this year's contest did not come in time for this issue, so the following are based on last year's rules. The contest is similar to the 21-28 MHz contest, except scoring is different.

EXCHANGE:

RS(T) and serial number starting with 001.

SCORING:

Score 50 points per BI QSO for non-European stations. An additional bonus of 20 points for each different British Isle country/number prefix worked is also available (36 maximum). NO BONUS FOR GB PREFIXES! Final score is total QSO and bonus points.

ENTRIES:

All entries should be mailed to: The HF Contests Committee, c/o John Bazley G3HCT, Brooklands, Ullenhall, Solihull, West Midlands, ENGLAND.

RESULTS

RESULTS OF THE 1976 BARTG RTTY CONTEST

Top 10 single operator stations –

I8AA	282,624 points
I1PYS	281,506 points
K4GMH	192,520 points
I5WT	177,054 points
DJ6JC	176,364 points
PY2CYK	166,680 points
IT9ZWS	166,584 points
WA3JTC/ZP5	149,400 points
W4CQI	133,480 points
HB9AVK	131,152 points

Top 3 multiple operator stations –

W1MX	156,240 points
SM6FUG	140,302 points
DL8VX	127,296 points

Top 4 shortwave listeners –

H. Ballenberger (DL)	133,632 points
R. Giarnello (I3)	116,480 points
Cech Lubos (OK2)	105,258 points
Paul Menadier (USA)	80,276 points

MANITOBA QSO PARTY
Starts: 0001 GMT Sunday,
October 17
Ends: 0300 GMT Monday,
October 18

The third Manitoba QSO Party is sponsored by the Amateur Radio Clubs of Manitoba. The same station may be worked on each band and mode. VE4 to VE4 and 2 meter simplex QSOs are also permitted.

EXCHANGE:

RS(T), name, and QTH-municipality.

SCORING:

Each QSO counts 1 point. VE4s multiply number of QSOs by the number of US states, VE provinces, and DX countries worked. All others multiply the number of QSOs times the number of Manitoba municipalities, local government districts, provincial parks, and forest reserves (134 maximum).

FREQUENCIES:

SSB – 3770, 3905, 7195, 7230, 14190, 14285, 21245, 21355, 28600; CW – 3705, 7105, 14065, 21205, 28205.

AWARDS:

Certificates for the highest score in each province, state, and country. Plaques for highest VE4 and out-of-province station. Additional plaques awarded if warranted.

ENTRIES:

Send log data and signed declaration to: Doug Bowles VE4QZ, 1104 First Street, Brandon, Manitoba, CANADA R7A 2Y4. Mailing deadline is November 12, 1976.

CQ WORLDWIDE DX CONTEST
Phone
Starts: 0000 GMT Saturday,
October 30
Ends: 2400 GMT Sunday,
October 31
CW
Starts: 0000 GMT Saturday,
November 27
Ends: 2400 GMT Sunday,
November 28

Rules should be the same as last year's contest, barring any unforeseen changes (please check the September issue of *CQ Magazine*). The basic idea is to work as many other amateurs around the world in as many zones and countries as possible. Use all bands, 160 to 10 meters – on specified mode only. Classes of competition include: single operator single band and all band, multi-operator (all band only) single transmitter or multi-transmitter.

EXCHANGE:

RS(T) and zone.

SCORING:

Score a multiplier of one for each different zone and each different country contacted on each band. Remember, stations are permitted to contact their own country and zone for multiplier credits – so don't forget to work other US stations! The *CQ*

LETTERS

PERSONALLY INVOLVED

I appreciate your acceptance of kudos and brickbats for suppliers of electronic gear. It affords an opportunity nowhere else available, to my knowledge, to report on one's personal experience in this area. The purchase of a major piece of gear with most hams takes place every few years; some suppliers, therefore, do not see the need for purchaser satisfaction as an inducement for subsequent sales, and only consider the sale at hand.

I welcome, therefore, this opportunity to praise the service and personal interest in my needs by one of your advertisers, Slep Electronics Co. My initial concern of dealing with a supplier outside of my geographic area was allayed by my feeling that Bill Slep was personally involved.

Andrew J. Bartilucci W2NKC
Garden City NY

ABOUT TIME

In conjunction with this 1976 bicentennial year I am working with the Maiden committee, who will plant a time capsule in Maiden, to be opened in the year 2076.

I want amateur radio to be part of this capsule. Please arrange to send me one copy of your July, 1976, *73 Magazine*. I would like, if possible, Wayne's autograph across the front cover. This will be part of the capsule contents which will be buried on the grounds of the Malden Government Center.

Mel Dunbrack W1BHD
Malden MA

Well, Mel, while I'm flattered, it is difficult for me to believe that anyone much is going to be around in 2076. — Wayne.

RESURRECTION

I'm sending this to you with the idea that it might help someone with a similar problem. I have a 12 year old pre-Novice friend named Brian. Brian secured a 1948 vintage Hallicrafters S-53 receiver for $10 (he'll mow my lawn three times and have it paid for). The S-53 was perfect in every way but one — it didn't talk. After a few minutes of troubleshooting we found a bad audio output transformer. A quick search of the junk box produced no audio output transformer (thought I had one somewhere), but I *did* find a 120 V/6.3 V filament transformer — hmmm, why not? I connected the 120 V side to the 6V6 output and the 6.3 V side to the speaker voice coil. Ta-Da, it worked! And the transformer even fit the same holes in the chassis. Mismatch? If there is any, it certainly doesn't affect the performance of the receiver by any noticeable degree.

So what do we have? A previously "dead" receiver brought back to life, an idea for a different "source" for audio output transformers, a happy boy (soon to be a Novice) who will soon be on the air for a $10 outlay (will loan him a transmitter). Now I ask you, can any CBer match this for sheer satisfaction?

Bob May WA4DBG
Jonesboro TN

ENOUGH TO PAY FOR IT

There is a newsletter, *Dr. Dobb's Journal of Computer Calisthentics and Orthodontia*, whose sole purpose is to find good software through cooperative efforts and put it in the public domain. Subscription: $10/year. Vol. 1 numbers 1 and 2 are probably still available; they contain a complete octal and symbolic listing for a Tiny BASIC interpreter for the 8080. If you do not object to not paying royalties, these could be your first software tapes (although they would probably object to your making a profit). The *Dr. Dobb's Journal* people — People's Computing Company, Menlo Park CA, are software types, I think, who probably have much to give to a group of hardware types such as yourselves. They are planning a disk operating system for a micro.

I like your magazine (enough to pay for it). I am a non-ham into personal computing. I would be happy to share my knowledge of systems and scientific programming with someone who can help me learn how to build and design my own system. Initial uses would be text editing — I am an academic type — and later super cheap graphics.

As an old-fashioned computer user (who would never mention DEC and IBM in the same breath), let me suggest a piece of hardware computer hobbyists really need, although they may not know it: a cassette tape recording system which can move forward or backward under computer control, and which can read forward or backward (and possibly write forward and backward). A tape recorder with these simple properties could store data in discrete blocks and read them rapidly and randomly — thus acting like a slow floppy disk. A floppy disk costs $1000 minimum — this cassette could cost $100-$200. My model for this tape is DECtape™ or LINKtape which can be used by mini and large computers *just like a disk*, only slower. You don't always have to start reading at the beginning of the tape to know where you are, so getting information is much quicker. This type of storage would allow sophisticated macroassemblers and compiler languages and real operating systems which would allow your computer to do what computers do best, more than one thing at the same time (would you believe writing one program while another is being assembled — that is easily within the speed capacity of micros right now!!). In addition, software for a block-structured tape medium could be trivially converted for a floppy disk system (perhaps even vice versa). Enough of my showing off my need for a computer text editor.

I wish you and your magazine the best of luck. I would be interested in writing for you if you think I might have something to say. Now that I've paid my money, don't stop with the computer oriented articles.

Bill Pearson
Pasadena CA

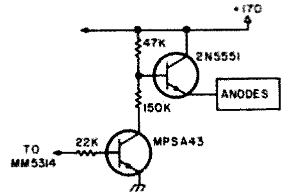
P.S. Computer Operations, Lanham Maryland 20801 sells a LINK tape for the PDP-11, LSI-11 and any 8 bit micro for $2k. Perhaps they could be convinced to make a kit for less, but the cassette idea is cheaper. If they can do it, you (we) can do it.

Love to have you write, but try to remember that I do not know what a macroassembler is, or block-structured tapes . . . and things like that. You'll have to bootstrap me to where I can understand what you are saying. — Wayne.

BRIGHTER DIGITS

Thank you so much for publishing "Behold The Giant Nixie Clock," by Jack Grimes W4LLR. I built it pretty much as per the article in your July issue, and it works just great! You wouldn't believe how many comments it has drawn from visitors in my lab.

I would like to make several suggestions that can result in much brighter digits. First, I built mine in a large metal box, so I had to use an isolation transformer. A transformer with a 6.3 volt and 125 volt secondary from a junked VTVM supplies the power. If you use this arrangement, you'll get over 170 volts B+, and brighter nixies. Also, I checked the transistors off the surplus boards on a Tektronix Curve Tracer, and found



that the UL624 units could handle only 24 to 72 volts, so beware! None of my SA480 units were any good, and none of my substitutes worked well, so I subbed the accompanying circuit, which replaces Q8-Q13.

The 2N5551 transistor may be any 50 to 60 volt NPN unit; it only switches 40 volts. The Motorola MPS-A43 may be nearly any 180 volt switching transistor. Finally, I changed the 3000 pF cap to 0.015 uF. The results are far superior to the original circuit using those ancient (ugh!) transistors!

Gary McClellan
La Habra CA

FIRE ONE

Chalk up another -1 for Trigger Electronics. About 1 year ago I placed an order and sent along my charge card number. Somehow the prices on items ordered went up an average of nearly 30% since the date on the catalogue I had just received. Some items nearly doubled! One that doubled I sent back and purchased locally for about the original (reasonable) price.

Thanks for providing a forum in which we can sort out reputable mail order suppliers.

Harrison K. Clark WB2YKH
Clifton Park NY

WHY BUILD IN AN ERROR?

The "Instant Counter Calibration" in the August issue describes a procedure I have used for some time, and it works well. The frequencies printed, however, are slightly in error.

Color horizontal frequency was originally selected so that, divided into the 4.5 MHz intercarrier, an integer would result, 286 yielding the closest to the original 15,750 Hz. In order to interweave the sideband clusters' horizontal-rate multiples from both visual carrier and color subcarrier, the subcarrier is centered between integral multiples, i.e., 227.5 times line rate, or 15,734.26573, yields 3,579,545.455 Hz.

This is all well and good, but in practice, horizontal, as all other pulses, is derived from a subcarrier frequency source, which the FCC has *defined* as 3,579,545 ± 10 Hz. The network rubidium standards output this center frequency, so the ".455" does not exist. As a result, the actual horizontal rate is 15,734.26374 rather than your published 15,734.265. While .08 ppm may seem insignificant,

considering the potential accuracy of this reference, why build in an error?

Other notes: The old monochrome standard, using 15,750 Hz, is almost never used in broadcast stations. Any network program will be using color standard, regardless of program content. "Mini-cam" frequencies will be as accurate as other network sources if not a live pickup, as videotape machines will lock to the house standard, that being rubidium for networks. Even local programs will have sufficient frequency accuracy for most counters, as the FCC requires ± 10 Hz, or .000279%.

Dave Powell WA4BRI
Lexington KY

NO KEYER

I ordered 20 "recent" ('71-'75) back issues of your magazine. They made interesting reading. Boy, OM Wayne really gets nasty in some of his editorials. A friend who subscribes to your magazine and I found them enjoyable. I finally broke down and bought the June '76 issue in a radio store, and I couldn't pass up the three year subscription offer. I find the computer articles interesting, as I am a Navy data processing technician. Also found the "Glass Arm" article in the June issue enlightening, since I am a CW freak at heart and use a straight key in all my CW contacts. Adjusting the key as mentioned in the article really makes a difference. I might stick with my straight key and not even buy a keyer.

Martin S. Roe WBØJNV/KH6IOO
FPO San Francisco

THE HUMAN FACTOR

I am writing in reference to the clock article on page 70 of the July '76 issue of *73* describing a digital clock using Borroughs B7971 Nixie tube readouts. As a clock builder since the introduction of the MM5314 clock chip, I would like to call your attention to the following errors in the schematic diagram presented with this article:

1. Leave pin 1 (output enable pin) of the 5314 unconnected or connect it to pin 12. It is shown connected to ground/vdd, which will blank the display.

2. The capacitor labeled 3000 uF is a bit large for this application. This capacitor sets the multiplex frequency of the display, and should be 3000 pF (that is, smaller values of this capacitor *raise* the multiplex frequency — a 3000 mF as shown would blink slowly, *if it would work at all!*).

3. The emitter of transistor Q8 is not connected on the diagram. It should be connected to the emitter of Q9 (that is, the +150 volt supply line).

4. The SA480 transistor is a PNP type; your artist drew them as NPN types.

5. You might advise your readers that the pinouts for the MM5314 chip as shown on your diagram would be as you were looking from the bottom of the chip, and not from the top, as ICs are usually shown.

Mr. Grimes should be applauded for his excellent article, and, of course, his courage in experimenting with the "unknown" UL624s, and SA480s from the boards. The fact that no one knew how much these would stand has probably prevented the purchase of these board assemblies by a great many.

Gary Joe White WB9BUU
Pittsfied IL

Dear Gary Joe:

Your comments are appreciated. Some are correct, one not correct.

Two of the errors are my fault — as *73* simply copied my circuit and I was in error in copying my rough sketch.

These two errors are PNP transistors drawn as NPNs, and the lack of a connection on Q8 to the 150 V line.

Your no. 1 comment concerning pin 1 — look closely. It is *not* connected to ground. That is simply a tie point to connect pin 2 and the 100k resistor to vdd. There is *no* short connection over to pin 1. So this is no error, but one might have to look closely to realize there is no connection to pin 1.

My original sketch specified 3,000 mmfd (or pF) — which dates me as rather ancient to use mmfd. So this was probably an artist's error.

The schematic is drawn almost as the board is laid out.

I apologize for my part in the errors, but I guess that is the human factor.

Jack Grimes W4LLR
Memphis TN

FIRE TWO

I am writing to let you know of the troubles I have had ordering a Hy-Gain 18AVQ/WB vertical antenna from Trigger Electronics.

On December 12, 1975, I sent them a money order for $82.01 and received notice that they got my order. A month went by, so I wrote them and said either send the antenna within two weeks or return my money. A month later I received a postcard from "customer service" telling me I would receive my order within 4 weeks! Two months went by so I wrote again and begged them to return my money. A month later I got another postcard from "customer service" telling me to send back the card along with shipping instructions because *my order* was *in!* I sent back the card and again told them to return my money. I even wrote a letter to the owner, Irael Treger W9IVJ, but I have gotten no response. I am really mad now and am trying to get help from the Direct Mail Marketing Assn. and from "Mr. Fixit" of the Philadelphia *Evening Bulletin*. I wrote to you so you will not accept their advertising and for any possible help in this matter. I notice that Trigger used to advertise in *QST*. Thank you for your time and trouble and a very good magazine.

George Schmidt AA3NOY
Philadelphia PA

DRAMA

Send your most dramatic emergency ham experience for inclusion in my book, "Introduction to Ham Radio." Free copy if used.

Jerry Swank W8HXR
657 Willabar Drive
Washington Court House OH 43160

ONE OF THE BEST

I am not interested in ham radio, but do find *73 Magazine* has enough other material to be one of the best magazines.

Bill Trail
Guadalajara, Mexico

BOLT BELIEVER

J. K. Bach might, in reference to his article in the July, 1976, issue of *73*, like to have my corroboration of his statement that the diameter of a lightning bolt can be approximately eight inches.

Around 1940, I was working for Northwest Airlines as a radio operator, and was familiar with the evidence of lightning strikes on the aluminum shells of DC-3s. The metal was fused, in several cases, in about a 1/8" diameter circle, and the heated metal concentric to the fused spot was discolored out to the size of a quarter. In a freak incident, the aileron of a DC-3 in flight was in the path of a lightning bolt. The ailerons of a DC-3 are of linen, and the cloth had a hole approximately eight inches in diameter burned cleanly through it, with a very small ring of charring.

A picture was taken of the aileron by one of the mechanical crew at the Billings, Montana, service hangar, but it did not "turn out." So no record is available.

Kenneth G. Axvig W7EPL
Kremlin MT

TAKE MY ADVICE

For the past several years, I have been an avid ARRL supporter, and thought of *73 Magazine* as just a second rate magazine. Was I ever wrong! Our radio club subscribes to it, and I had a chance to read the club's copies of both *QST* and *73*. I have no choice but to subscribe to *73*.

Also, W8LWS was right. Don't build his world's smallest field strength meter. I didn't take his advice and went through a dozen of those 35mm film cans before I got one to work. The rf choke was $4.38 — the only part I didn't have in my junk box. It does look cute, but, *73* readers, wait for his next project. Take his advice, and mine.

Craig R. Schmidt WBØGFZ
Dickinson ND

NEW PROOFREADER

Well, I had better do it. I hereby request that you extend my present sub by an additional 3 years. I enclose a check for $17.76. Too bad I lacked the foresight (and the cash) to obtain a life subscription while they were only $37.00. Anyway, thanks for a tremendous magazine. (My dictionary defines *tremendous* as "huge, terrifying through great size or force" — close enough!)

In my article, "Build A Deluxe TTY Keyboard," published in the October and November/December 1975 issues, there are several errors. The basic keyboard described in Part I is OK, but the automatic function module in Part II contains some small errors and one large one. The following are the small errors:

1. Pin 2 of U213C should go to pin 8 of U213B, not pin 6.
2. Terminal A should go to pin 6 of U209, not pin 8.
3. U209 is a 74121.
4. There should be a 3.3 kΩ resistor in series with the base of Q203.
5. The diode connected to pin 13 of U213D must be reversed.
6. The 2 diodes connected to pin 4 of U203A must be reversed.

Now for the major error. The AFM (Fig. 2, Part II) connects to the wrong points in the basic keyboard (Fig. 5, Part I). In the basic keyboard schematic, terminals A and B are the connection points for AFM terminals 1 and 3 respectively. Well, that's wrong. Short terminals A and B permanently. Break the connection between U4A pin 5 and U7A pin 2. U214 contains a couple of spare inverters. One of those has to be used. Connect AFM terminal 1 to U4A pin 6. Connect AFM terminal 3 to U214 pin 9 (spare input). The output of that inverter (pin 8) should be connected to U7A pin 2. With the AFM connected this way, the serial input should be low when the keyboard register is empty (full of space coding).

As far as I know, that's it for errors. I'm sorry if anyone gave up on this project because of them. Next time I'll get a new proofreader for my author's proofs.

Bob Hart K7YGP/7
Medford OR

MICRO MAYDAY?

I am building an 8080-based microcomputer system, and would like to

get in touch with other hams who are also interested in microcomputers. With the growing interest in computers and computing among your readership, I feel that a small space in *73* devoted to getting us together would be appreciated by many — something like "Ham Help," but for we hams who are interested in computers.

Scott C. Crumpton WB4JTB
Gainesville FL

AIRPLANE! AIRPLANE!

Your July issue arrived June 8 and after finishing my evening munchies I turned to my favorite author, W. Sanger Green. Yes, I know, the period he writes about is for oldtimers. But then how many youngsters had the experience of everyone rushing out of their homes when the cry, "Airplane! Airplane!" was raised in the neighborhood. (Background noises were low in the '20s.) I've had the thrill of seeing the zeppelins floating south to a place called Lakehurst, N.J. Mr. W. Sanger Green is doing us a great service by recording the past and helping us to appreciate the progress made for our benefit in a few short decades.

Seeing his picture with Amelia Earhart gives one thought as to why offspring never seem to benefit from the handsomeness of their parents. My mother always insisted children tend to resemble their grandparents. Apparently, she was right.

I like the new magazine format. The change from 2m repeaters to minicomputers is fine, too, since I have neither. But, please, don't forget to include the simple construction articles. Not all of us have the time and facilities for the major projects. Still, the smell of hot rosin is preferred to aftershave lotion and lawnmower exhaust.

Joe Lisanis
West Caldwell NJ

I/O, I/O, IT'S OFF TO WORK . . .

I enjoy the I/O articles very much. I am a field engineer with Burroughs and I find that they supplement very well. Good magazine. Keep up the good work.

Tom Lawrence WB4QLW
Danville VA

MOSTLY BOURBON

Just a note of thanks for your "buy centennial" offer. I'm half Scotch, quarter English and the rest is mostly bourbon I think, but a bargain of this kind cannot be ignored, especially since I just borrowed a current copy at *QST* to find out what the cat left in the tuna can.

Only four — count 'em, 4 — articles that I can even remember being in the issue (I just looked at it yesterday), and acres of contest results and advertising. More ads, it seems to me, than *73*, and less magazine. That's nonprofit?

The point I'm getting to is that I personally value *73* highly as 1) entertainment, 2) instructive literature, 3) reference material, and, yes, 4) inspirational enough to get me off my duff to build things I can't buy because nobody makes it, and 5) knowing you get your feet muddy by not living in an ivory tower. As a comedian (Dave Gardner) once quipped when referring to a preacher's sermon on sin, "How's he know so much about that if he didn't ever?"

You and the gang keep up the good work and I'll be pushing up daisies before my subscription expires. Thanks again.

Chester C. Childs W5HVJ
Metairie LA

THE HUMAN TOUCH

Many thanks for running the article by Anthony Curtis K3RXK, "What's Up on 156 MHz?" in the July, 1976, *73*. It was very well done, and sure filled a gap that I have long been curious about. I am sure that the fleet will find the article very handy!

By the way, I have done business with one of your advertisers, and find that John Meshna is everything that a businessman should be. I just wish more people could be like him. He certainly handled my small business with the human touch. I ordered just a small bit under $10, but he was out of stock of the item . . . but he did have a set of bristol wrenches I wanted. He sent me the $10 back, and also sent the bristol wrenches! You can't beat that!

CIRCLING PATTERN

I very much appreciated the article by Chester Brent WB4GVE, entitled "Aim Your Beam Right" (*73*, June, 1976). Chester is to be congratulated for finding a workable, short solution to great circle computation problems, despite his self-confessed "rusty" math.

While the method presented should be quite OK for most U.S. amateurs, a few will not be fully satisfied. The choice of positive signs for *east* longitude and negative signs for *west* longitude was unfortunate for users of the HP-65 computer who are used to precisely the opposite usage of designators for east and west longitude (all NAV PAC programs standardize on positive values for *north* latitude and *west* longitude, and on negative values for *south* latitude and *east* longitude). Also, the symbol used by Mr. Brent for latitude (λ) is the one used almost universally for *longitude*. Latitude is generally abbreviated as Lat or simply L.

For those readers having access to the HP-65, here is a simple modification of the Great Circle Navigation program (NAV 1-10A) which will compute the beam heading between any two points on the globe. With this version, you only need enter your QTH latitude and longitude once. As an added bonus, the program automatically calculates the distance in nautical miles between any two terrestrial points.

The program accompanies. To use it you merely:

1. Key in your location using standard DDMM.m notation as follows (assume your QTH is Chicago, 41°52' N, 87°38' W):

   4152 Enter 8738 A

2. Key in desired location, say, Perth (32°00' S 115°54' E):

   3200 CHS Enter 11554 CHS B

3. The HP-65 will automatically calculate and display the beam heading in true degrees (290.2°). If you then want to know the distance to Perth, simply press C and it will be immediately displayed (9531.4 nautical miles).

For new locations, begin at step 2 above.

SUB TIME

Thanks for a great magazine. I've been buying it at the local electronics store for almost a year, and decided that it's time to get a subscription. I especially enjoy your computer artjcles. I've been a computer programmer for about 10 years, and it seems that we get further away from the machine all the time. This is great for getting a particular job completed, but not as much fun. I'm in the process of trying to decide which micro to buy.

I'm also buying a set of your code tapes in hopes that they will help overcome the mental block I have against learning code. Been trying since the Boy Scouts, with no success.

Richard R. Zeh
Dayton OH

LITTLE BROTHERS GROW UP

Right on baby, right on! Your editorial in the July '76 issue was more on the mark than all the so-called sophisticated comments I've read in the past five years put together. I think you hit the nail right on the head. Nothing gets changed unless someone stands up and yells, loudly. It does little if any good to stand in a corner and mumble about the bad old "them." If you feel like you have been wronged, scream, at the top of your lungs. True, the odds may favor that you will turn out to be the voice in the wilderness, but at least you will have discharged part of your responsibility to our 200 year old experiment in individual liberty and self-determination.

My on again off again relationship with *73* is now about six years old. No, I'm not a ham. As much as I would love to be a part of the fraternity, the code has baffled me for the better part of twenty years. But, I still enjoy tuning in your world on my R-4C and sharing some of the amateur achievements via *73*, and, yes, even *QST*. As somewhat of an outside observer, it strikes me that amateur radio and its headstrong little brother CB really represent the essence of what our American experience is all about – the freedom of people who think to communicate freely. Certainly, we will frequently disagree (wouldn't it be a pity if we didn't), *but at least we can communicate*, which is more than ¾ of our brothers on this globe are allowed to do. Most people forget, or don't know, that most everywhere else in the world you need a license for a receiver, let alone a transmitter.

Enough of my soapbox. Keep it up, Wayne. You may not win, but hopefully you will keep a few people thinking. After all, that's what it's all about. By the way, those hams willing to key a mike on (heaven forbid) Children's Band might notice something unusual – if you give your callsign in addition to your "handle," more than likely you will get a legal callsign back. Even little brothers grow up.

Doug Shear
Arlington TX

SOFTWARE SUPPORT

It's actually your excellent I/O section that I'm subscribing for. *Byte* has not lived up to its promise, and you have the vision and imagination – evidenced by the July editorial on the future of the home computer – to expand the I/O section wonderfully. Count on me to support your plan to distribute software. I'm in the market for anything entertaining that will run on my IMSAI with George Morrow's cassette board and PTCo's video board and BASIC and 20+K of RAM and still growing.

In the meantime, I'd like to have a copy of your tape of Ed Roberts' interview. I want it for my archives, but if it will make you feel better I will gladly share it with the North Texas Computer Hobbyists Group, to which I belong.

Dan Wingren
Dallas TX

. . . AND AS WE ARE!

Enclosed are the proof sheets for my article (*Upcoming. – Ed.*). They look good to me. Sorry to be a little slow but I just got back in town. Of all things, I was in the northern mountains making radiation measurements on a mutilated cow. A real weird deal. Some thing that flew in a vehicle with tripod landing legs and that walked all over the place leaving four inch circular foot prints, removed the lips, ear, tongue, and rectum of the animal. All this was done without leaving any blood or signs of bleeding.

Also the vegetation wilted and died near where the legs of the vehicle rested. Sounds like I am cracking up but I was working with the New Mexico State Police and other officials. They are as confused as I am.

Howard Burgess W5WGF

TO ERR IS HUMAN

Regarding my article in the July, 1976, issue of *73*, "Perfect CW – drive 'em crazy with the Keycoder I":

In the Parts List, I neglected to give the part number of the recommended Amidon Associates' toroids. It is FT-50-75 (price: 65¢ each). These are the ferrite (not powdered iron), high permeability cores needed for this project – some others we tried didn't work.

Also, in the schematic: R9 (1k), that feeds pin 2 of F/F 7, should be connected to +5 V dc, and the Vcc connection to IC2 (the monitor) should be labeled pin 8.

Yes, I know you sent me the galleys to check, but "to err is human," and I hope you'll be divine and forgive these oversights.

I've had 3 congratulatory letters on the article to date, from one of which I quote: "Thanks again for the fine article of the type which keeps me a current Wayne Green subscriber."

Bob Way WA9VGS
Hales Corners WI

SOMEDAY

Haven't got very far into minicomputers yet, but am reading all the articles and maybe I'll be inspired to buy a few chips and experiment. (The prices of the complete units are beyond my means and I'm sure beyond most hams' pockets – but they will come down someday.)

Henry Pattee W5POH
Mountain Home AR

C(W) URCHIN

You won't believe the popularity of your code tapes. On vacation, I encountered a street urchin in New York who could not live without your 5 wpm cartridge. He was in such a hurry that he took the tape recorder it was in, too. Oh, well . . . enclosed is a check for a new one. Tape, that is. Don't know what to do for a tape recorder yet.

from page 8

share of the revenue. Everything – lobby, dining room, guest rooms, etc. – was spacious. Eaton and I each rattled around in a large two room suite. The only bad feature was that it was too far from the Export office to walk – particularly on the uphill return trip. When Cleo and I were in Genoa in 1963, I drove up to what had been the Miramare hoping to stay there, only to find that it was by then a convent.

A week was spent in Genoa conferring with Gehan and his staff. Eaton and I had to get used to slowing down our working speed to half throttle. The Export offices were in an old palace on the Via Garibaldi. The palace had no central heating, but it did have high vaulted ceilings that were painted hundreds of years ago with biblical scenes. The days went something like this: Get to the office about 9:30 am, out for a capuccino at 11:00, then to the Union Club at 13:00 for a few drinks, a game of dice and lunch (excellent food). Then back to the office at 15:00 and work until cocktail time (19:00). Dinner was usually around 21:00 at someone's home or at the "Buca di Santa Matteo," "Gambrini's," or another fine restaurant. Then possibly a few rubbers of bridge and we were ready to "hit the sack."

After much discussion about procedure, it was decided that I should take a look at the possibilities for flying boat operations at Marseilles, Algiers, Oran, Casablanca and Tangier. Jim Eaton was to go to Paris and confer with our ambassador regarding French landing rights possibilities, for survey flights. So on December 23rd I flew to Marseilles in an Ala Littoria Savoia-Marchetti twin-hulled flying boat. That afternoon I went to Algiers in an Air France flying boat. The next morning was spent with the Export agent and the U.S. consul. The Algiers harbor seemed to be OK for flying boat operations. That evening I caught the wagons-lits for Oran, about 250 miles away.

Very, very early Christmas morning I debarked from the train at Oran and checked in at a hotel to get some more sleep and freshen up a bit. After looking over the harbor and deciding it wasn't our "cup of tea" I dispensed with the formality of disturbing the agent's holiday. Instead, I treated myself to a very fine roast goose and liebfraumilch dinner and got the afternoon train for Casablanca (about 500 miles via Oujda, Fez, Meknes and Rabat). A very comfortable journey with good accommodations and service. Of course, there was the usual commotion at the frontier. All very polite.

Before leaving Genoa, John Gehan advised me to live at the Hotel Excelsior while in Casablanca, so I checked in there on my arrival. Since it was Saturday, I phoned Toledano & Son (Export agent in Casablanca) and told them I was in town and would be in to see them Monday morning. They were expecting me and invited me to tea on Sunday. They were a very nice family and I enjoyed several fine meals with them. I spent over a week based in Casablanca. The port was entirely inadequate for our purposes, so I got Joseph Toledano to drive me up to Port Lyautey (about 85 miles). On the way we made a courtesy call on the U.S. minister at Rabat to advise him of our plans. Port Lyautey provided the only adequate place for a large flying boat base on Morocco's Atlantic coast. Its disadvantage was its distance from Casablanca (85 miles) and Rabat (25 miles).

On January 4th I was ready to return to Genoa, so I phoned the Export agent at Tangier to see if any passenger ship for Marseilles or Genoa was sailing in the next few days. They had a Rotterdam-Lloyd ship, the *Indrapoera*, departing for Marseilles on the morning of the 6th on her way to the Dutch East Indies. I asked them to arrange space for me to Marseilles on the *Indrapoera*, and, since I was coming up to Tangier on the evening train, to reserve a room for me at the El Minza Palace Hotel. Quincy Stanton, our consul in Casablanca, gave me a "laissez-passer" to get me through Spanish Morocco. They were having a good-sized revolution going on in Spain at the time between Franco and the communists, and I didn't want to get caught with my passport down (no Spanish visa). It was lucky I had this document, for when we got to the frontier the train filled with armed soldiers. They not only checked passports, but also examined all luggage and personal papers. They spoke no English and I no Spanish, but they were plainly not happy about my passport. Something that the "laissez-passer" corrected. I still don't know which side those fellows were on.

In the morning, I called on U.S. Ambassador Blake and obtained advice from him and information of value from his abstracts and files. The afternoon I spent sightseeing. Next morning, I boarded the *Indrapoera* at 8:30 for the trip to Marseilles. On the evening of the 7th they had a big party aboard to celebrate the wedding of Princess Juliana of Holland to Prince Bernhard of Germany. We arrived at Marseilles at 10:30 on the 8th and I was back in Genoa before midnight on the chemin de fer.

Next month, to Egypt.

Looking West

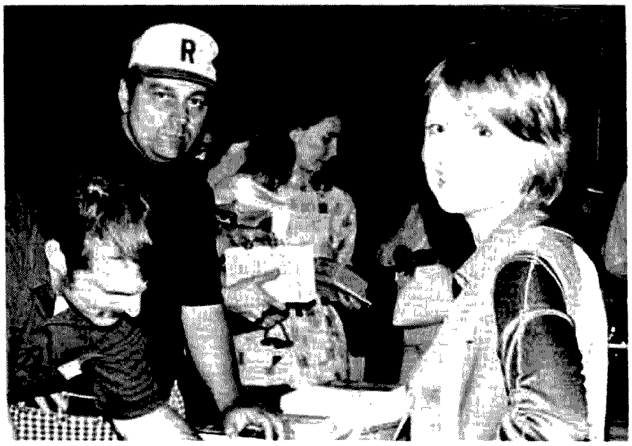
Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

Many of you have asked how this column got started. Honestly, many times I have wondered this myself. Actually, the story is quite simple, and I hope it might be the kind of inducement necessary to get some of you interested in writing about the many diverse aspects of this wonderful world we call amateur radio.

"Looking West" began about three weeks before I left New York City in 1972. I had mentioned to Wayne that I would be driving cross-country, and the thought occurred to me that the seeds of an interesting article might be found in the fact that I was equipped for two meter FM. Anyway, about one month and three thousand miles later we arrived in the promised land, and I took out my notes about the trip and proceeded to write an article entitled, "Looking Back Ahead." To say the least – the very least – it was bad. After all, it had been exactly ten years since I had sat before a typewriter, that prior effort being a product review of the then-popular Clegg 99er six meter transceiver. At any rate, I do not blame old Never Say Die for turning down "LBA"; as I reread it now, I realize how lucky you all were to have been spared the agony.

Anyhow, earlier in 1972, *73*'s now long-gone *Repeater Bulletin* had carried an interesting article on Southern California FM by Bob Greenberg WB6INR. In fact, during August of '72 when I had ventured out here to seek employment, I had a chance to meet with Bob and his lovely wife Rene and learn a bit more about the Southern California FM community. Since Bob's article/letter had but scratched the surface of this interesting part of the nation, and being undaunted by my rejection notice on "LBA," I proceeded to write the first of what has since become a regular feature of this magazine: the only amateur radio FM column devoted to letting you know what's happening in this fascinating part of the country, with the technological advancements, the interesting people, and even the politics. This is all a part of the Southern California FM scene, a scene that I take great pride in being a part of, and even greater pride in sharing with you. Now, thanks to you, we are beginning to branch out a bit and are slowly getting into a position to bring you information of happenings elsewhere in the nation and the world. The column is finally developing into what I always hoped it would: a forum for developing lines of dialogue between amateurs of common interest everywhere. As I have said before, I consider "Looking West" your column. I may write it, but without you and your input the whole effort would be for naught. So thanks to all of you from a grateful writer, and I sincerely hope that in the future we will continue to serve you well. Now . . . on to DAYTON!

Ever flown on a Boeing 727? That's the aircraft with three engines mounted in the rear (one on either side, and the other as part of the tail just below the elevator assembly). Let me tell you, when that baby climbs out you know it . . . it's some moving machine. It was on such an aircraft that we departed New York's La Guardia Airport about 8:30 am for an hour or so breakfast flight to Dayton, Ohio. Two and a half hours later we were checked into our Holiday Inn. We hopped into the Avis rental for a nonstop trip to Dayton's Hara Arena, home of the 1976 Dayton Hamvention. (At this point I should digress for a moment and offer special thanks to TWA for a fantastic on-time flight, to Avis for having our rental car waiting promptly as we arrived, and to the folks at the downtown Dayton Holiday Inn for some good accommodations. I always hear people complain that big companies "don't really care." In my case, they sure did care, and this is a personal thank you to all three.)



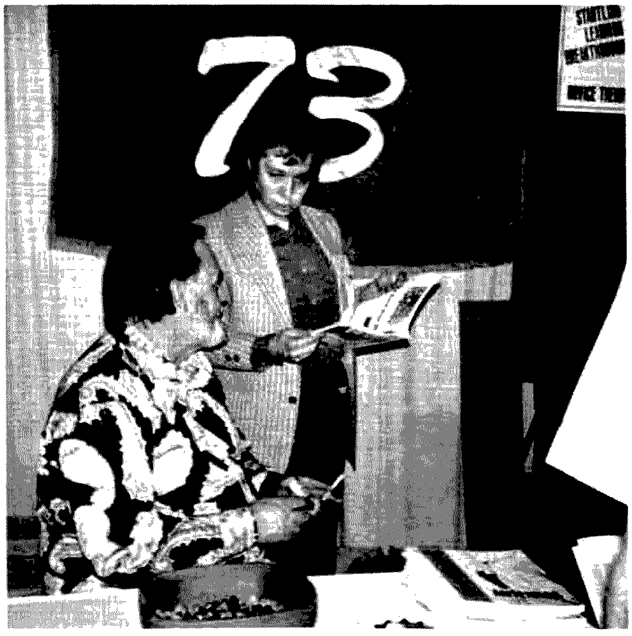
With a smile like Sherry Smythe's, how could anyone resist buying a sub?

While I have been to a good number of amateur conventions in my time, including the biggie in Las Vegas called SAROC, what greeted me at my arrival at the Hara Arena was almost hard to believe. (Please refer to the August aerial photo cover on *73* if you do not believe this report; it will more than substantiate it.) Acres upon acres of vehicles sporting amateur callsign plates and/or other identification that proved them a part of the amateur community were in attendance at this unbelievable gathering. I had heard many stories about the Hamvention, especially from my buddy Fred Deeg K6AEH, but until I saw it firsthand I really did not believe all that I had been told.

Somehow, Sharon and I made it to the ticket/information area, identified ourselves as being part of the *73* contingent and were given excellent directions as to where the booth was located and how to find it. About five minutes later we arrived and were quickly pressed into service. The place was a madhouse, with amateurs from all over the nation, and, as we found out later, all over the world, stopping by to say hello and buy subscriptions or other *73* goodies. To let you in on a secret, both Sharon and I were having the time of our lives. While it was work, for both of us it was a labor of love.

Since I had noted what seemed to be rain clouds moving in when we arrived, I excused myself for a while, and, after making the rounds to see the exhibits and say hello to many friends, I headed directly to the flea market, Bell & Howell Super 8 camera in hand. What I saw and also recorded on film was beyond my wildest imagination. If there were acres of autos in the parking area, there must have been as many acres of flea market. Standing as far away as I could and still be able to get an

W2NSD/1 eyeballs with WA2DHF.



WA6ITF (standing) and Advertising Director Bill Edwards WB6BED/1 hold the fort.

Larry Moldauer WA2PZI drops by to say hello.

A familiar face at many conventions, Fred Deeg K6AEH takes a break by relaxing at the 73 booth.

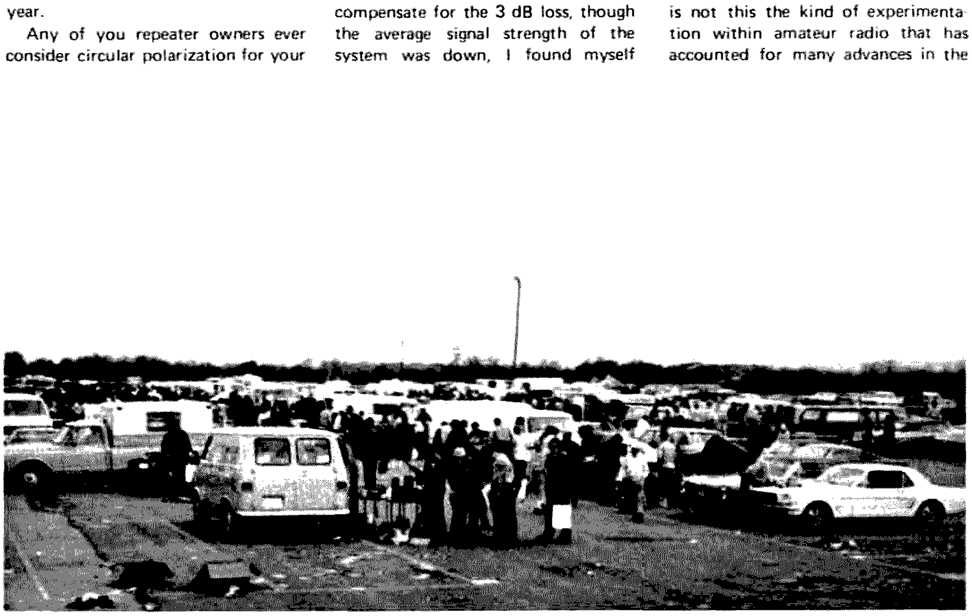
unobstructed view, and with the camera set at full wide angle (approx. 9 mm), it was impossible to photograph the entire flea market without resorting to the well known slow pan shot. It was also impossible to cover the entire flea market in the few short hours I could devote to it. I suspect that I got to see about a third of it firsthand that day. My only regret was that I had spent almost all my bread in NYC on such "unimportant" things as clothing and the like. Here I stood in the middle of "ham heaven" without a paltry farthing in my pocket. There were many goodies I would have loved to have carried home aboard that L-1011, but maybe I was smart in letting my better half handle the financial aspects of our Dayton stay.

No sooner had I arrived back at the *73* booth than I heard, "So this is where you have been hiding!" I turned around to be greeted by Steve Mendelson WA2DHF, long-time friend and now Secretary of the newly-formed Tri-State Repeater Council serving New York and vicinity. Now, you might find this hard to believe, but somehow, even though I had spent the previous week in the big apple, Steve and I kept missing each other. Now, about 900 miles west, we finally got to eyeball. Steve eventually took off (after we had made a dinner date), and I got back to work, but only for a minute or two. Up walked one of our closest east coast friends, Larry Moldauer WA2PZI. I cannot tell you how long this friendship goes back. I guess I've known Larry ever since I've been a ham. It's one of the beautiful friendships that develop from amateur radio and last a lifetime. Larry and I have flown airplanes together, sold and swapped ham equipment over the years, attended each other's weddings, worked contests, and done probably everything else that two friends with common interests can involve themselves in. Since time in New York had been short, we had not been able to drive to Jersey to see Larry and Linda. The time we had to spend was all too short, but I did get a promise that he and Lin would be out to visit again this summer. For me, the best part of Dayton was that it was a chance to renew old friendships such as those with Steve and Larry, with a myriad of other old "SUR" people, and with many LIMARC members that I have known for years.

Yes, the southland was more than well represented. Many of the people that you have come to know through this column, such as Fred Deeg K6AEH, Capt. Dick McKay K6VGP, and "Uncle" Earl Surad WB6MUQ, to name but a few, passed by the booth to say hi. Dayton to me signified something very special: a mingling of the minds and hearts of amateurs from all over, on a face-to-face basis. I sincerely think that this, more than anything else, accounts for the success year after year of this event. Dayton is the "ham convention of conventions" and you have but to attend once to realize why. If I were never to attend another convention, at least I could say I was a part of the better than 12,000 amateurs who were Dayton 1976. God willing, I will be there next year.

Any of you repeater owners ever consider circular polarization for your system? This is being tried by one of the major Los Angeles open repeaters, WR6ABE. When the Stationmaster that normally serves the system was taken down from its perch 200 feet above Mt. Wilson, it was replaced with a specially-manufactured JAN-PRO circularly polarized broadcast type antenna cut for 146.40 MHz. While CP is quickly becoming a trend in FM broadcast radio, I am told that to date very little experimentation has been tried in the use of CP for two-way FM communication, and therefore little is known as to how well it might work in comparison with the now standard and widely accepted vertical polarization. Burt Weiner K6OQK decided that 'ABE might be an excellent testbed for such experimentation, and therefore went from a 9 dB gain antenna to a 3 dB loss antenna. While no final conclusions have been drawn yet, my personal observations might interest you.

Most noticeable are two things. First, before power was raised to compensate for the 3 dB loss, though the average signal strength of the system was down, I found myself hearing the repeater in places I had never heard it before. Not well many times, but it was there and that amazed me. The rapid flutter normally encountered in poorer areas had now become something akin to "low band" fade, due, I suspect, to the minimization of multipath loss. While what users term overall system sensitivity (the ability to burp the system from 20 megamiles past normal coverage area) was obviously lowered, you could now walk around your living room, HT in hand, without having to look for that one special spot from which to talk. You could also turn your hand-held sideways and not lose the system. So while users on the fringes may have suffered a bit, and while many a user gripes that he can no longer use 'ABE twenty miles past Podunk, by and large the CP experiment does seem to have a lot of merit. Much valuable information is currently being gathered, thanks to the inquisitive mind of Burt Weiner K6OQK, owner of WR6ABE. After all, is not this the kind of experimentation within amateur radio that has accounted for many advances in the



Acres and acres of flea market...

world of communication? Again, an amateur has proven that you can do more with a repeater than just talk over it. Who knows what advancement this, as well as the earlier WR6AJP CP experiments, will lead to?

In the meantime, if you are interested in working with CP or possibly have some ideas or experiences to share with Burt, he can be reached by dropping a note to Burt Weiner K6OQK, c/o The Mt. Wilson Repeater Association, PO Box 10193, Glendale CA 91209. I suspect that Burt would be interested in hearing your ideas.

While on the subject of WR6ABE, we regret to announce the temporary (we hope) discontinuance of the weekly bulletin service. After better than two years of uninterrupted service, Bob Sudock WB6FDF has found it necessary to step down from the position of producer-editor-narrator of this weekly service. Speaking for many amateurs, I know that Bob will be missed. The true professionalism that he brought to this service will be long remembered by many of us here and in other parts of the country where the bulletin service was taken by tape delay. While the search is on for a replacement for Bob so that the bulletin service can again resume, I for one feel that he will be a hard act to follow. Thank you, Bob, for a job well done.

On the topic of amateur radio bulletin services such as this, Bill KH6IAF recently returned from the Island State with word (and tape) that a very similar service had been instituted there. Using a format similar to Mt. Wilson's, and the facilities of the interlinked Hawaiian repeater system, amateurs there now have a chance to get up-to-the-minute information on things that concern them. Congratulations to the KH6s who have taken the initiative on this worthwhile project!

"Moving Up To Amateur Radio"

Once again, the expertise of filmmaker Dave Bell has brought forth a production of outstanding merit. However, unlike previous productions on the subject of amateur radio, "Moving Up To Amateur Radio" is the first such film that is intended for a non-amateur audience. It is an 11 minute experience designed to introduce the wonders of amateur radio to those who have in the past been exposed only to Citizens Band radio or to no form of two-way hobby radio at all.

NBC-TV News correspondent Roy Neal K6DUE is your host and guide. He starts by very tastefully comparing Citizens Band radio with amateur radio and explaining in the simplest of terms the differences between the two. He then takes the viewer further into the world of amateur radio by explaining how one goes about obtaining the necessary training to obtain an amateur ticket, and then on through a tour of the many diverse aspects that combine to make amateur radio one of the world's most interesting hobby services. The audience is allowed to glimpse such things as DXing, RTTY operation, slow scan TV, amateur satellite communication via the OSCAR satellites, and FM. The film ends with a two meter repeater QSO that truly epitomizes the fun of that aspect of amateur radio.

The main question is: "How well is the public going to respond to this film?" If my experience is any indication, I suspect that this vehicle by itself may bring many new members into the amateur radio community. Though the film was not intended for public school audiences, I had the opportunity the other day to make such a showing. Before screening the film, I asked the audience how many of them had an interest in amateur radio. The response was two hands rising above two young heads. We ran the film and again asked the same question. Now 16 students showed interest, and many expressed a desire to take the school's amateur radio training class. The film had done for this audience what it was hoped it would do for all audiences: act as the necessary catalyst for fostering interest in the world of amateur radio.

"Moving Up To Amateur Radio" may be the key that many of us have been looking for, the key that will unlock the door to growth within the amateur radio community. To that end I am happy to commend "Moving Up To Amateur Radio" to the non-amateur world – and especially to the members of the Citizens Radio Service. Through this film, those outside the amateur world can learn not only about us, but, also more important, how to become part of us.

Build a Weird 2 Band Mobile Antenna

--fantastic parking lot car locater

If you have operated 75 and 40 mobile, you are well aware of the problem of stopping (on a freeway?) to switch resonators on your antenna only to wish you had stayed on the other frequency. Wouldn't it be great if you could switch bands even more conveniently than in your home station . . . no levers, switches, sliders or moving parts?

Here is an electronically switched multiband mobile antenna that can be built with the minimum of parts that are available at the corner home improvement discount house.

I had been anxious for a no-nonsense, non-mechanical multiband mobile antenna for years. The final straw, however, occurred somwhat suddenly one stormy afternoon away from home in our travel trailer. I was talking to a long-time friend across a couple of states and without warning he suggested we shift from 75 to 40 and "click" — he was gone. Normally this would not have been a big deal, but under the circumstances it was downright inconvenient.

This was in 1969, and almost the first person I saw after returning home was Walt W6IJA. He came to our place sporting a three band antenna on his mobile.

Walt had all three of his resonators, 75-40-20, mounted fan fashion on a single base section fed with a single feedline. It was so stupidly simple and practical that I had carbon copies installed on my car and travel trailer within hours. Using just about any resonators available, most of the mobiles in the area were multiband from then on. See Fig. 1.

Not All Roses

Even with the W6IJA multiband antenna, I kept looking for that better mousetrap. Along the way there were plenty of failures. One that I think worth mentioning was what I thought was my greatest pride and joy.

By early 1971 I had a dual bander that looked just like a monobander going down the road. Simply, it was constructed with two insulated top whips laid side by side and held together with shrink tubing. One whip was attached to the top of the coil for 75 and the other brought down to a point where it would resonate on 40 meters (see Fig. 2).

The rig used was a small low powered 75-40 SSB transceiver. The antenna was used mobile for over six months and I was so convinced "this was it" that I submitted a patent disclosure.

Then one weekend I shifted it over to another vehicle with a higher powered rig. After the second syllable — nothing — complete failure. Looking outside toward the antenna, I saw a neat little smoke ring drifting across the canyon! Inspection revealed that the whips had arced through the insulation and they were shorted together at the center. Every type of available insulation was tried, but anytime anything but the little rig was tried . . . fireworks! Back to slaving over a hot soldering iron.

Mother of Invention

Then there was the time I completely demolished my W6IJA dual band antenna with no spare parts for miles around. I did salvage enough

for a 75 meter resonator and a couple of top whips, and I was going to be content to get out and short out a few turns to get on 40.

The more I thought of this the less I liked it, having been spoiled by the dual band convenience, so I haywired together a modified version of the earlier "Ol' Smokey." See Fig. 3.

This worked the very first try, and the antenna noise bridge indicated a good match to the 50 Ohm coax on both bands using the old tried and true "Z" match at the base. A surprise bonus was several dB gain in signal strength over the monobanders.

Within a few months this model was cleaned up mechanically, using easy to obtain parts and far fewer of them. Also, the current model described in this article is a little easier on the eye. With a large number of them on the road for the past few years, it has exceeded all expectations. Mechanically it is rugged – none has been reported broken. It has been operated thousands of miles in ice, snow, mud, rain, hot and cold. Everyone has been pleasantly surprised with the performance.

During six months in 1975 the XYL and I traveled 15,000 miles to the four corners of the United States and we never missed our daily 75 meter schedule to the home base in California. Time, 1900 PST; frequency, 3830; rig, TR-3 with the big DK antenna.

No, This Is Not a Broadband Antenna

It may be redundant, but I have to repeat that, like any other good HF mobile antenna, this is not a broadband device. In my travels to clubs last year this was usually the first question that was asked. This appears to be a point that has eluded even a lot of the old-timers. Maybe it is just wishful thinking.

When you are messing with a high Q HF mobile antenna, twiddling the transmitter knobs will not make the antenna work any better. The antenna must be resonant and then matched to the feedline. The more abbreviated the antenna is in relation to the wavelength, the less the usable bandwidth. That's just the way it is! See Fig. 4.

For some of the hard to convince, I have tuned and matched their transmitters to good fifty Ohm dummy loads and then switched it over to the antenna to prove that twisting the transmitter knobs wasn't the secret to get the antenna to take the load. As a matter of fact, this is a very acceptable way to match your antenna to transmitter and feedline. Just switch off from the dummy load and then do all the adjusting to the antenna system to obtain maximum output. The big DK as shown will present a 50 Ohm load at the base on both 75 and 40. The swr will be less than 1.1 to 1.

Preparing the Coil Form

The loading coil is wound on a nineteen inch piece of one inch, schedule 40 PVC pipe. The 1" is the inside dimension. It's a little over an inch and a quarter on the outside. You should be able to bum this much pipe out of your friendly plumber's scrap box. When you cut off the ends, use a pipe cutter if possible to be sure they are square. Don't use too much pressure and crowd the cutter.

With a straightedge, lay a line the full length of the pipe along one side. Measuring from the bottom end, accurately mark points at 1", at 7

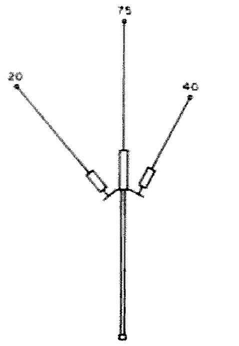

Fig. 1. The 1969 W6IJA special.

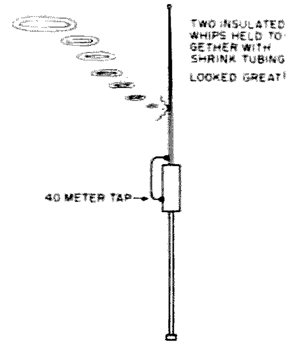

Fig. 2. Ol' Smokey.

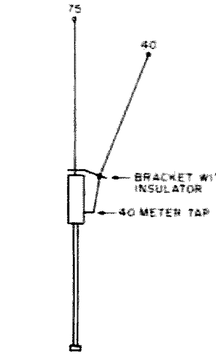

Fig. 3. The 1972 impromptu dual bander.

1/8" and at 17 5/8". Use a number 30 drill and drill holes through the side of the pipe at these points. At the 1" mark only, drill on through both sides of the pipe (see Fig. 5).

The next step is to install the bottom plug to provide the mechanical and electrical connection to the usual 3/8-24 stud that is found on mobile antenna base sections. If you dig around in the plumbing supplies, you can find a regular 3/4" to 1/8" pipe bushing that has a lot of threads both inside and out. The inside 1/8" pipe threads will be tapered and it may be necessary to run a 3/8-24 tap all the way through so it will screw all the way onto the bottom mast section. The cast bushings are not so good, but usually in the same bins there will be ones that appear to be machined and are also plated. A brass bushing would be dandy.

Screw this bushing into the bottom end of the pipe until all the outside threads disappear. Here's where a lathe would be great, because it is important to get this plug in straight so the antenna will stand at attention properly when it is finally mounted on the vehicle.

The pipe bushing will screw in very tightly and makes its own threads as it is turned in. Be sure the pipe is at room temperature so it won't crack. I have never used any glue or cement to hold the bushing in and have never had any reports of any coming loose. Believe it or not, this makes a really rugged mount. I have hit low obstructions with the coil hard enough to break off the bottom mast section with no damage to the coil.

When the bushing is in, drill and tap for an 8-32 screw on the side of the pipe, through the PVC and into the bushing. Do this directly below the 1" point where the number 30 drill came out opposite the penciled line. This screw will be used for the lower coil connection.

Winding the Coil

Winding the coil is really the most difficult part of construction, particularly if a lathe is not available. The coil is wound with 196 turns of #18 solid copper wire space wound to 12 turns per inch. The 40 meter tap will pass over the tap hole at the 71st turn. 85 feet of wire will be sufficient to wind the coil and leave plenty to play with on both ends.

Before you go at it the hard way, check with one of the local adult education classes where someone is taking shop and a lathe is available. Set up the lathe for 12 threads per inch, run the wire through a guide on the tool post, and it will take the operator about one minute to wind the entire coil. Note how the start and finish wire is dressed through the holes in the PVC coil form (see Fig. 6).

Also, if I am winding on a lathe, I spray a thin coat of adhesive on the pipe just ahead of the winding to help keep the wire in place. Sometimes when I am not in a hurry, and can leave it in the lathe for a while, I brush on a generous coat of fiberglass resin or varnish over the windings and let the coil keep turning while the stuff sets up. This makes a very attractive finish and it can even be painted to a color of your choice. Just be sure you are careful about the kind of paint used. No metallic particles, please! I have been that route.

If resin or varnish is used, be sure to put a toothpick or some similar plug in the 40 meter tap hole so it can be cleared later without damaging the wire.

Those of you who have shrink tubing available can go ahead and use it over the coil; it works fine. Also, it is advisable to drill a small drain hole on the side just above the bottom plug. I found this necessary as I unscrewed my coil one day to show it off. The coil holds exactly one coatsleeve full of water!

As I say, if you can get to a lathe, you have it made. I would certainly make every effort to locate one. If not, there are other tedious ways to space-wind coils, but one this size gets to be a problem. Our luck has been that when the XYL and I are very carefully winding one by hand, the phone will ring. The question is who drops what, or do you just start over only to have the whole thing "clunk" together at the very last turn?

A popular way, of course, is to select another piece of wire or a string that will give the correct spacing, and then

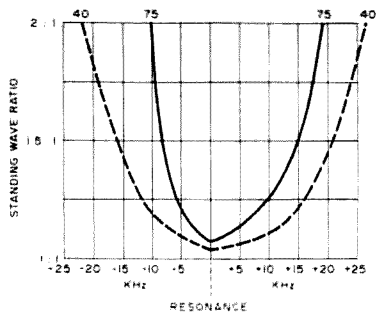

Fig. 4. Swr curves for typical big DK.

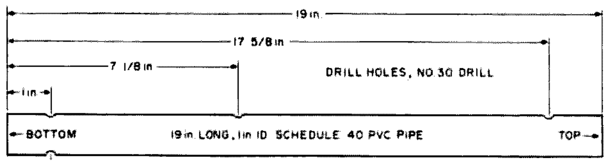

Fig. 5. Preparing the coil form.

wind it side by side with the coil wire. When the winding is completed and secured, the wire or string is carefully removed.

Preparing the Coil Wires

Remove the insulation from the end of the bottom coil wire and place it securely under the 8-32 screw that goes into the side of the 3/4" pipe bushing. I use a brass screw and then a dab of solder to be sure there is a good electrical connection. This is a low voltage point and it is wise to continually inspect all connections from here on down to the feedline to keep the I/R losses to absolute minimum. Dissimilar metals and constant exposure to the elements encourage trouble, causing corrosion in a very short time.

For the 40 meter tap I use an eighteen inch piece of the inner insulated conductor from stripped RG-58U or other similar small coax. Strip the insulation from this inner conductor 2" on one end and 3" on the other. Be sure there are no nicks in the wire.

Remove the insulation from the coil winding that passes directly over the hole drilled for the 40 meter tap (turn 71). Be sure you don't take any insulation off the adjacent windings. Clean out the hole under this wire.

Now shove the wire just prepared down through the inside center of the coil form from the top so that the bare end stripped 2" comes out through the 40 meter tap hole. This is not hard to do. Put a long 90° radius on the bare 2" end and then hold the pipe and wire in such a way that as you shove it down toward the tap hole you have a good chance of it coming out on the first try.

Pull this wire out so the insulation is tight up against the inside of the 40 meter tap hole. Use a small soldering iron and solder this wire to the winding that passes over the hole. Put a little bend or hook in the end of the tap wire to help hold it mechanically. Try applying a little pressure to this connection with the soldering iron, pushing it just below the outside surface of the PVC. Don't push too hard or you'll have a horrible mess. When soldered, carefully trim off the excess wire and examine closely to make sure there are no solder blobs or bitter ends touching the adjacent windings.

Cut off the wire coming out of the coil from the 75 meter hole so the wire extends three inches beyond the top end of the pipe. Remove two inches of insulation from the 75 meter wire. Tin both the 75 and 40 meter wires. Now your masterpiece should look like Fig. 6.

Preparing the Tee

The support for the two whips on top of the coil is a one inch PVC pipe tee that slips on the top of the completed coil. When obtaining this fitting, ask for a "slip-slip-slip" one inch PVC tee for 1" schedule 40 PVC pipe. No threads.

Drill two 5/16" holes, 1 1/4" each side of center, through the top of the tee for

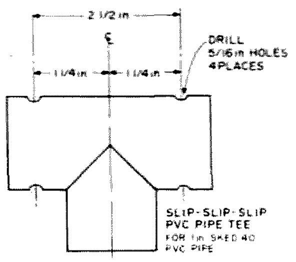

Fig. 7. Preparation of PVC tee for top whips.

mounting the two whips (see Fig. 7).

It is important that these holes are absolutely parallel to both the sides and ends of the tee. A drill press is a big help here but it can be done with a hand drill if both sides are very accurately marked and caution is used while drilling. Don't let the drill or the tee wobble and make the holes egg-shaped because this will affect the proper installation of the whips. Of course where I drill a large number at a time, I have cheated and fabricated a fixture so if I make a mistake I have a box full of instant surplus!

Installing the Tee

Align one open end of the tee so that it will line up with the hole where the 75 meter wire goes through the side of the pipe. Place the 75 and 40 meter coil wires up into the tee and out their respective ends, and push the tee onto the coil end. Be sure that the open end selected is still lined up with the 75 meter wire hole. This is very important to provide maximum clearance between the 75 and 40 meter connections. Also be positive that the two wires are not crossing over each other inside the coil form or the tee. There are tremendously high voltages here and precautions must be taken to prevent arc-over. When the alignment of the tee is verified, tap it all the way down onto the coil form as far as it will go. I use a rawhide hammer.

Here again I have not found it necessary to use any PVC cement because this slip fitting is plenty tight and, if necessary, it can be driven off again. The coil now looks like Fig. 11.

The Top Whips

The top whips on mobile antennas usually take a pretty good beating from low branches and flourescent bulbs in service stations. They have to be flexible enough to give when an immovable object is struck, but still stiff enough to recover to the original position without taking a set.

The position that a top whip maintains determines the exact resonant frequency. It should not wave around too much while underway. This is why I do not use, nor recommend, a spring mobile mount. The mobile antenna must maintain the same relative position to the vehicle at all times to keep it at resonance. When you see someone tearing down the road with the antenna swinging wildly in the slipstream, you'd better get in contact quick, because by the time he gets down to the next corner he's going to be out of range!

Over the years I have tried various brands and combinations for top whips, but there was always something lacking. Many times the price bothered me. Currently I am using 1/4" diameter solid fiberglass poles covered with copper braid. The best source for these fiberglass poles in small quantities is the six foot bicycle safety flag. Cheap, too; less than a buck.

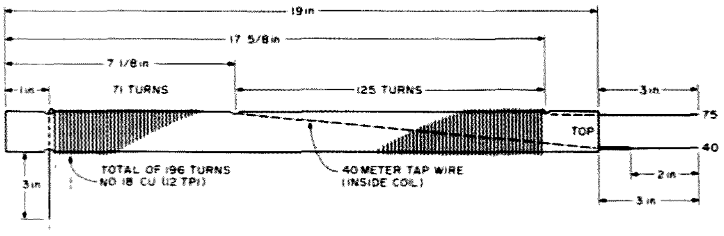

Fig. 6. Big DK loading coil.

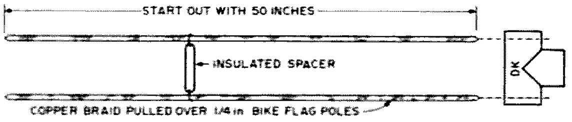

Fig. 8a. Fiberglass whips.

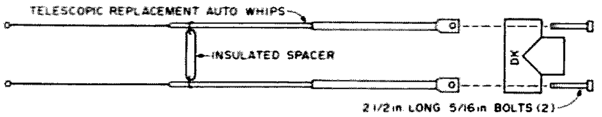

Fig. 8b. Adjustable auto replacement whips.

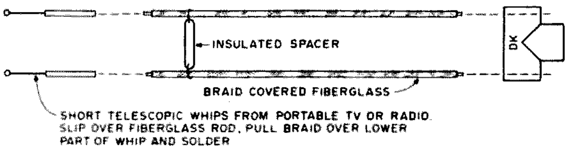

Fig. 8c. Adjustables on fiberglass whips.

Probably the best source for the copper braid to slip over the fiberglass poles is some old scrap coax. I found some old RG-6U and used the silver tinned braid. It looks real classy while it is new.

To make the whips using the fiberglass poles, cut two of them 50" each and slip the copper braid over them. Pull the braid up tight on both ends, give a good twist and cut off the excess (see Fig. 8).

Later on, the whips can be painted, doped or just left as is. My Sunday antenna is striped FAA orange and white. It gets a lot of attention. When the other driver hesitates for the second look, you get the jump on him at the traffic signal.

Alternate Top Whips

You might come up with some alternate top whips which will work as well as the cheapie bicycle flag poles. A couple of the local mobileers have used their retired fiberglass CB whips and just pruned them down to resonance. Another ex-fisherman used two of his old tapered hollow fiberglass fishing poles. For the conductor, he just merely shoved a #12 copper wire up through the center and, when it was trimmed to the proper length, he soldered a neat little corona ball on top.

Automobile Replacement Whips

I have also used a number of the automobile replacement whips (Fig. 8b). These are the type that slip over the 5/16" diameter auto whips that get ripped off. One source is the Ward TCFR-1; another is Radio Shack part #12-1309. These telescopic whips are not really the greatest for mobile use because when they hit something they normally bend and take a set which puts the antenna off resonance.

For the travel trailers and mobile homes and other stationary installations, the replacement whips work out just fine. The advantage, of course, is being able to vary the length easily if you have the urge to move around the band.

Installation of the Top Whips

Installation of the braid-covered fiberglass whips is relatively simple. With the braid pulled tightly over the 1/4" fiberglass poles, they will go into the 5/16" holes in the PVC tee with a very snug fit. Push the whips on through so the bottoms protrude out the bottom holes in the tee about an eighth of an inch (see Fig. 8).

Pull the 75 and 40 meter tinned coil wire leads around their respective whips. Take up all the possible slack from inside the coil form and then solder to the braid on the whips (Fig. 9). Be very careful that the PVC tee doesn't get too hot. It melts very easily. Cut off any excess wire and dress so that sharp ends are pointing toward the outside ends of the tee. If you have some Glyptal, it won't hurt to coat these connections. Don't leave any debris that might encourage corona inside the tee.

Use a piece of the leftover 1/4" fiberglass rod for a spacer to hold the two top whips parallel. Cut the spacer 2 1/4"; drill two small holes crossways close to both ends. Thread a 2" piece of bare wire through each hole. Place this spacer between the whips about 36" up from the tee, wrap the bare wires around the braid and then solder to hold it in place.

Be sure you can identify which whip is which, and then plug up the open ends of the tee. Cap-plugs that are often used to protect pipe threads can be modified to snap in. Maybe you have a couple of spare plastic shot glasses.

Finally glue, dope, epoxy, or what have you around the four holes in the tee where the whips fit.

Bottom Section

The bottom section of the mobile antenna should be installed to place the bottom of the antenna coil a minimum of 6" above the highest part of the vehicle. The length of the bottom section will vary with the location of the base mount on the vehicle. I have installed lower sections with lengths varying from 18" to 6 feet without degrading the efficiency of the antenna. Anytime any part of the loading coil is placed below the highest part of the vehicle, the radiated signal suffers considerably.

Bottom Section Fabrication

A very simple, sturdy and cheap antenna bottom section can be made from a piece of 1/2" EMT – thin wall conduit. Cut off the desired length and then in each end braze a 5/8" by 1/2" long hex-head bolt. Chuck this up in the lathe and drill and tap 3/8-24 both ends (see Fig. 10a).

If a lathe is not available, you'll have to come up with the old "drill a hole in the bolt trick," which could be to sneak it in on one of the local shop teachers while your coil is being wound.

Antenna Mount

While you are at it, you might as well go all the way and make your own base mount. This can be done with a 1" bolt and a few homemade insulating washers.

Dig out a bolt that has no threads within a couple of inches from the head. Make a very square cut and saw off the threaded end and discard. Using the same "drill a hole in the bolt trick," drill and tap a 3/8-24 hole 3/4" deep in each end. Cut out a few washers from some good insulating material and drill the

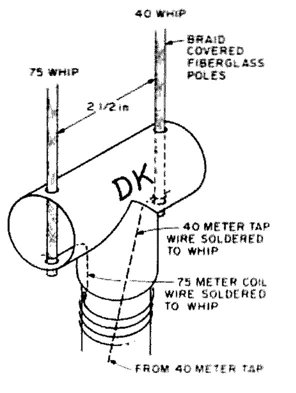

Fig. 9. Detail of coil wires' connection to whips.

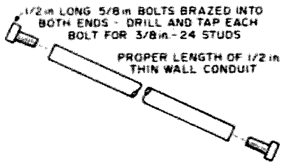

Fig. 10a. Lower mast section.

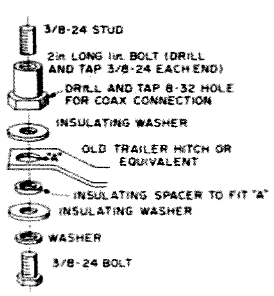

Fig. 10b. Homemade antenna mount.

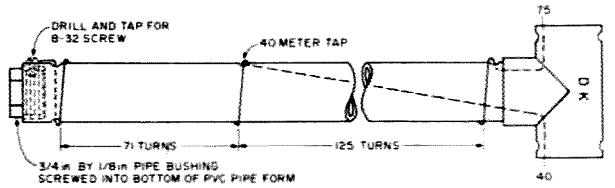

Fig. 11. Completed loading coil ready for whips.

centers of each with 3/8" hole. Assemble as in Fig. 10b.

Matching Capacitor

The capacitor across the antenna end of the feedline preferably should be a variable with a range that goes through 500 pF to 1500 pF. I was able to pick up a few compression screw driver adjusts, Arco part #310. These worked out very well and they could be put right on the money for a good match. The way to adjust the cap is to jump back and forth from one band to the other, readjusting the capacity for the lowest swr on both bands with the same setting. This will affect the resonant frequency of the antenna a small amount, so be sure you have the capacitor in place and adjusted close to the correct value before pruning the whips the last few kHz. See Fig. 12a.

If one of the adjustable trimmers cannot be located, start out with a fixed 820 pF silver mica. It is very possible the 820 pF will give an swr of 1.1:1 or less.

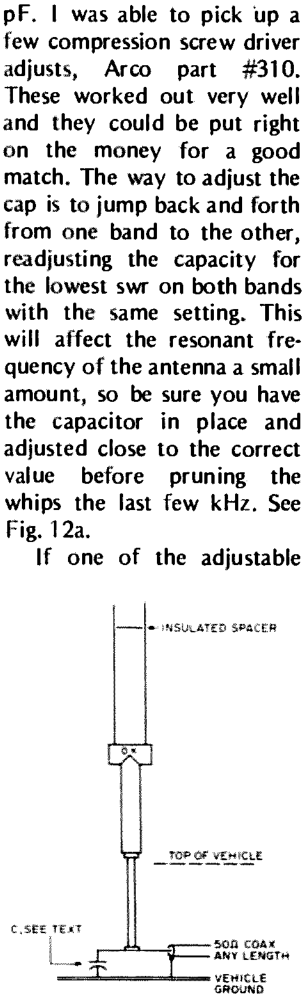

Fig. 12a. Installation.

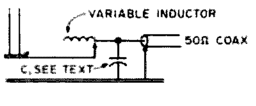

Fig. 12b. Installation of variable inductor.

Pruning the Top Whips

With the assembly installed on the vehicle as in Fig. 12, connect the antenna noise bridge in the line and look for the resonant point on both bands. Using the braid-covered bike whips, each 50" long, will place the antenna quite low on both bands. Thinner whips, however, will require lengths up to twenty percent longer.

First of all, if you are using a variable inductor at the base, as in Fig. 12b, be sure it is set at the minimum inductance before you start pruning and tuning.

If resonance cannot be located starting with the 50" whips, don't overlook the fact it may be so low that it is at a point below the frequency range of the receiver.

Slide the braid down on the whips, saw off one inch of the fiberglass, pull the braid back up tight, give it a twist and cut off the excess. Continue this, cutting off shorter and shorter pieces until the desired resonant point is reached. It is very doubtful that the whips will be much shorter than 46" each when the antenna is completed. Don't get confused; be sure the proper whip is being trimmed, because it gets embarrassing when one of the whips keeps getting shorter and the frequency does not change. After the last and final prune, pull the braid up tight again, give it a twist, put a bit of solder over the end and trim off smoothly.

Normally one inch removed from the 40 meter whip will raise the frequency 50 kHz. One inch removed from the 75 meter whip will raise the frequency 25 kHz.

Using the telescoping types of top whips will make tuning a lot easier, but you are not going to be happy with them mobile unless you have some of the exceptionally good ones made particularly for this type of service.

Random Info

This antenna has been developed in various other directions: 160 and 75 meters; some three banders, 160-75-40 and 75-40-20; two whips on the same band, permitting CW and phone band without retuning the antenna; MARS and amateur.

On mobile homes and travel trailers, a base section of approximately 14 feet, plus or minus a little, will permit operation on 20 in addition to 75 and 40 by just using the two whips. The big DK on the top appears as a top hat on the 20 meter 1/4 wave vertical.

With the antenna mounted on the rear of the vehicle, the resonant frequency on 75 will go down as much as 30 kHz when a travel trailer is hooked on behind. Likewise, if you have the antenna installed on a travel trailer and then connect the tow vehicle – zip – down the band it goes again. The amount of shift depends on the location of the antenna in relation to the added vehicle.

Don't expect any directivity from 75 or 40 mobile antennas. The pattern around a vehicle on a properly installed 75-40 meter antenna is very symmetrical. If someone says "I'm headed toward you now and I should be louder," – don't get sucked into agreeing with him.

A properly matched antenna presents a 50 Ohm load at the base, and the length of coax feedline has no effect on the resonant frequency of the antenna. Of course I would not recommend a couple of hundred feet under the front seat; it gets sort of lumpy.

It may be noticed that I did not mention "roller" inductors for the QSY variable coil at the base. There are other ways to produce a variable inductor, probably right out of the scrap box. Think about it.

Another way to lower the frequency of a fixed whip is to alligator clip a "stinger" on the whip right above the tee and let it trail aft (see Fig. 13). A clip and a piece of wire with an overall length of 8" will move the 75 meter resonant frequency down about 30 kHz.

One owner mounted a tiny telescopic antenna out of the 75 meter end of the tee. He can reach this adjustable whip out of the pickup window while underway. We call him "Hot Fingers Ralph."

Another mobileer starts out early in the morning, checking into a weather net, and then drops 25 kHz down the band. He installed his

spacer at the very top of the whips. At the center he wedges in a 4" plastic spacer to bow the whips out from one another in the center. This four inch plastic temporary spacer is attached to a fishline leading into the car window. After he checks out of the weather net he jerks the spacer out and pulls it in the car. Presto! He's 25 kHz down the band. The next morning the spacer goes back in. This illustrates how important it is to keep the two whips in the same relation to each other at all times.

The bicycle poles with the braid covering are also doubling around Wireless Hill as 2 meter verticals, VHF and UHF beam elements. Uses around the station are limited only to the number of bicycles ripped off.

It is best to orient the tee on the antenna crossways to the vehicle. This allows for better fore and aft flexibility. Also it has been found that, with the tee aligned fore and aft, the turbulence from the leading whip creates a severe flutter to the trailing whip which causes the whole assembly to vibrate.

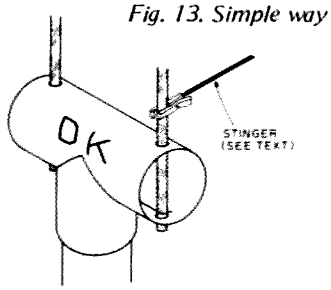

Fig. 13. Simple way to lower frequency in a pinch.

Acknowledgements

I want to thank the numerous amateurs who put up with my haranguing in addition to contributing their time, money, materials, ideas and field testing during the development of the big DK. They are all the greatest. This has certainly been a cooperative project and it is continuing. ■

New Products

HOW ELECTRONICS GOT FASTER AND EASIER TO WORK WITH THANKS TO MODERN SOLDERLESS BREADBOARDS

A P Products Incorporated of Painesville, Ohio, originated the modern solderless breadboard in 1968. Since then, tens of thousands of solderless breadboards have been used each month by electronics experimenters and designers in a wide variety of fields.

But just what is a solderless breadboard? How does it work? What advantages does it offer? Where can it be used? And how?

Before the era of modern solderless breadboards, designing and testing any given electronic circuit was an aggravating, tedious, time-consuming task. First a circuit would have to be designed on paper. Then the schematic diagram of the circuit would have to be translated into a circuit board parts layout for either point-to-point or printed circuit wiring. If a printed circuit were to be used, as was most often the case, the circuit layout would have to be transferred to a copper-clad board, the copper selectively etched, holes drilled, and components soldered in place. Then, if a component proved the wrong value, it would have to be desoldered and a new one soldered in place. If the printed pattern were in error, a whole new board would have to be laid out, etched, drilled, filled and soldered. A lot of time, a lot of work.

Then A P Products came up with the idea of arranging a breadboard with a matrix of interconnected holes. The interconnections are made by conductive spring clips that grip each component lead firmly to establish a good electrical connection without soldering. The matrix of holes was laid out in a tenth-inch spacing pattern to conform with standard component lead spacing.

The interconnection pattern was designed to provide ample access to each lead of each component, especially with modern transistor and integrated circuitry in mind. And distribution strips were designed to provide power and signal lines where needed.

Circuit designing now becomes plug-in-easy. ICs and/or discrete components plug into the solderless breadboard and ordinary 22 gauge solid wire jumpers are used to interconnect them.

A given circuit can now be prototyped in minutes rather than hours or days. Many designers work directly with component specification sheets, many with schematic diagrams. Changes in parts values are as easy as pulling out one part and plugging in another. And the geometry of the modern solderless breadboard translates into a printed circuit layout readily, once the circuit is ready to commit to hardware.

In addition, solderless breadboards can serve as a basis for semi-permanent circuits in applications where the need for a given circuit requires reliability but does not require longevity.

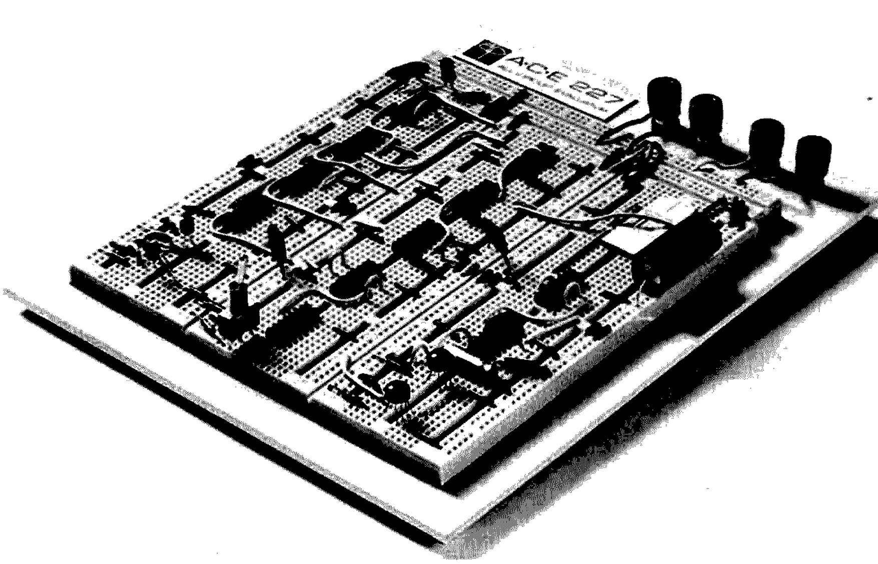
Applications for modern solderless breadboards are as wide as all of electronics. There are professional applications in machine control, data processing, test and measurement, device testing, prototyping and equipment adjunctive aids. There are hobby applications ranging from communications to photography to automotives to biofeedback to music to model railroading and more.

And, of course, solderless breadboards are perfect for educational and instructional applications.

Solderless breadboards and breadboarding aids come in many sizes and prices, capable of circuits as simple as you like or as complicated as a small computer.

A P Products continues to be a pioneer in the development and application of modern solderless breadboards. If you have questions about what solderless breadboards can do, how much they cost, or what's available, contact A P Products at Box 110, 72 Corwin Drive, Painesville OH 44077. A P Products has available a free catalog of their ACE All Circuit Evaluator solderless breadboards, Super Strips™, Terminal and Distribution Strips, IC Test Clips and accessories.

For more information, contact Robert J. Gabor, A P Products Incorporated, Box 110-P, Painesville OH 44077. Phone: (216)-354-2101; TWX: 810-435-2250. Direct all inquiries to Rita Mercer.



DRAKE RCS-4

Checked the price of RG8-U lately? Want to beat that price and clean up the unsightly mess of coax running down your tower? The boys at Drake have a real winning number for you.

The RCS-4 is a remote controlled switch that will switch 5 antennas from 1 feedline, ground those not in use – and will ground them all when not in use. Cheap lightning protection, right?

This unit will take full legal power, and operates up through 2 meters like a champ. Only 24 volts dc to motor – and has rain hat construction to prevent moisture damage.

This jewel works like a dream, with swr less than 1.5 to 1 even on 146.94. At $120.00 this has to be one of the top buys. We aren't easily impressed, but this got our attention. Switch 3 beams and a couple of inverted vees, all with only 1 up lead. Fantastic! Available at your dealers.

Build a Counter for Your Receiver

- - updating receiver fun

About 18 months ago, I sat down to design a simple digital dial for my receiver. I ended up building a deluxe, no-compromise received frequency counter. My reasoning was that with TTL IC and LED readout prices being so low, it would only cost a little bit more to go all the way. In retrospect, this appears to have been a wise decision. Component prices are still declining. During the development period, I had occasion to use the digital frequency readout with single, double and triple conversion receiving setups. All I ever had to do to change over to the new receiver was connect its oscillators to the counter and reprogram the count direction for each oscillator by means of a few wire jumpers.

The basic features of my digital frequency readout system are illustrated in Fig. 1. The multiplexed up-down counter principle is used. Since 4 inputs are available, the system is directly applicable to up to triple conversion receivers. The up-down controls for each input are made available as external connections. This facilitates reprogramming the unit for use with a different radio or with more than one radio. I found that tri-state logic buffers (8T97B, e.g.) are ideal for a multiple receiver interface.

The received frequency counter shown in place on top of my HRO-50T receiver. This chassis contains all of the circuitry described in the article except the crystal oscillator, power supply, and multiple radio interface. These are still in breadboard form and are not shown for aesthetic reasons.

The system has a 50 MHz

Jack Regula WA3YGJ
105 Sutcliffe Lane
Conshohocken PA 19428

guaranteed, 75 MHz typical maximum input frequency. Its error limits are ±¼ count times the number of counter inputs used, ± the timebase error. 100 Hz accuracy as well as resolution is readily achieved for a double conversion receiver with only a 6 digit counter. Since the counter updates its display at a rate equal to one twentieth of its resolution, 10 Hz resolution is still usable. I built a 7 digit counter with switch selected resolution. I don't employ the higher resolution in normal operation, but it comes in handy when aligning the timebase and when using the counter on the test and development bench. And, like I said before, it only cost a little bit more to add the extra digit.

Interface Design

The success of any digital frequency readout system hinges on the user's ability to connect it to his radios without upsetting their operation. Careful shielding and layout and avoidance of ground loops are necessary to ensure adequate isolation between the analog and digital circuitry. The biggest headache I had occurred when I created a logic signal from a bfo right on the receiver's chassis, then found I couldn't keep it out of the i-f. You can probably save yourself a lot of time by avoiding that mistake. An easily implemented and relatively foolproof interface is shown in Fig. 2. Use an FET buffer close to the oscillator tank circuit to isolate it from the logic circuits. Bring the buffered signal to the counter's chassis in coax with the shield grounded at only one end to avoid ground loops. If you have at least .6 V p-p at this point, an inverting tri-state buffer with resistor feedback will convert it to TTL levels. If gain is required, try a step-up transformer. If you've got a lot of signal, install a protective diode at the 8T98's input.

That's the circuit design. Systems considerations dictate a modular, expandable packaging approach. To prevent spurious responses in the receiver, we need to shield the high speed digital lines and to isolate the oscillator signals from each other. For these reasons, I put 2 sets of the interface circuits shown in Fig. 2 in a 2¼" x 1½" x 2" minibox. Female BNC connectors mounted to the minibox wall bring the oscillator signals in. Feedthrough terminals on the opposite wall couple the tristate TTL outputs to twisted pair lines daisy chained between the miniboxes. Each minibox contains a single 8T98 IC mounted in a wire wrap socket on a copperclad board. Isolated pads are cut to hold the discrete components. All of the interface miniboxes are enclosed in a larger metal box to shield the twisted pair lines. These lines are terminated, as shown in Fig. 3, and additional drivers send the signals to the counter chassis via coaxial cable.

While I haven't tried them all yet, several techniques are available for expanding this digital frequency readout system's versatility. By pre-

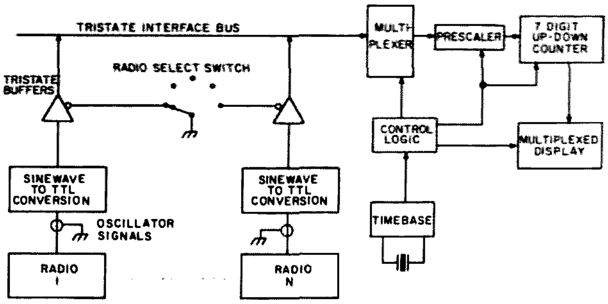


Fig. 1. Block diagram of digital frequency readout.

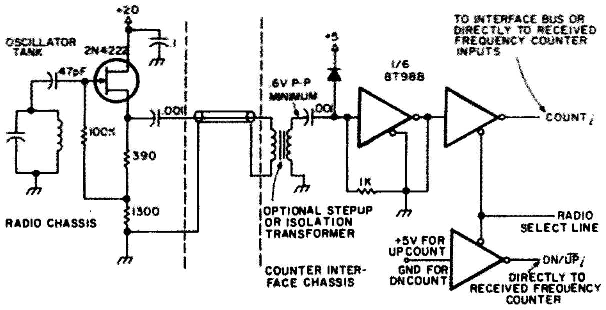

Fig. 2. Oscillator-counter interface details.

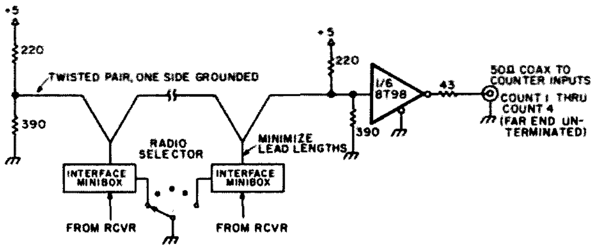

Fig. 3. Interface bus details.

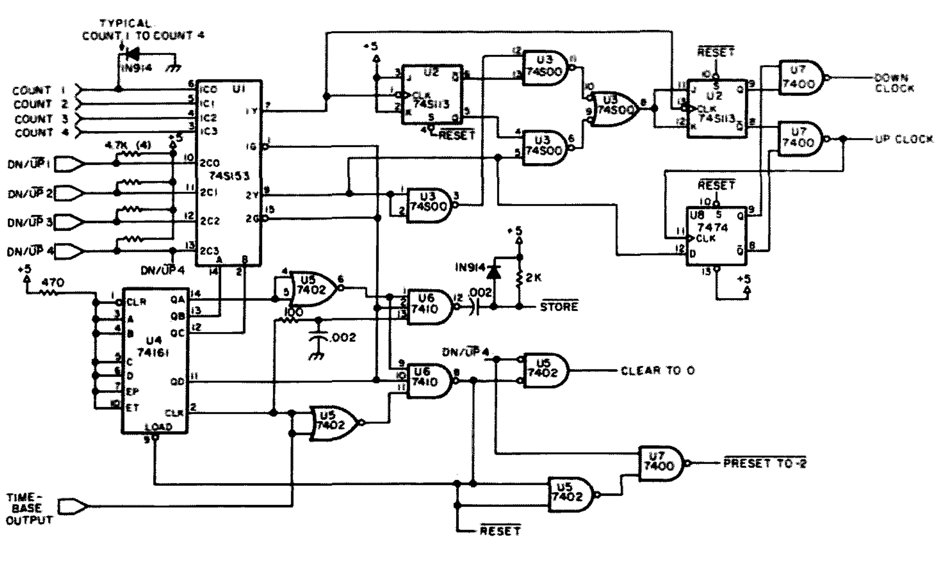

Fig. 4. Counter front end and control circuitry.

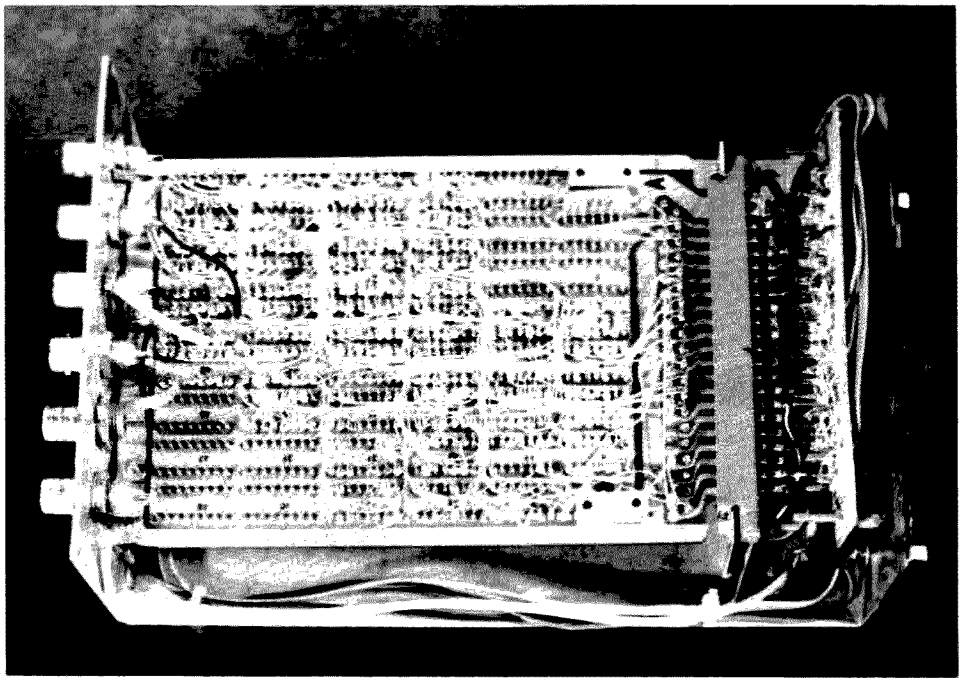
scaling every oscillator, you can use it with VHF and UHF converters. A frequency multiplying transmitter can be read out by connecting its vfo to 1, 2, 3 or 4 counter inputs, depending upon the band in use. With a voltage to frequency converter and additional control circuitry, you could fashion a digital voltmeter with automatic correction for offset voltage. Once you have the basic system built, I'm sure that additional uses will suggest themselves.

Counter Front End

The counter front end circuitry is shown in Fig. 4. IC1 is a dual 4:1 multiplexer. Its purpose is to scan the four COUNTi and the associated DN/UPi inputs, connecting each pair in ascending numerical order to the circuitry which follows. Short lead lengths and power distribution techniques are moderately important here due to the sharp rise and fall times of the signals involved. In particular, mount IC1 near a board edge so that short, direct point to point wiring can be used between it and the coax connectors on the chassis walls.

The top multiplexer output clocks a 2 stage up-down counting prescaler implemented with Schottky ICs for high speed. Its count direction is controlled by the bottom multiplexer output. The flip flop and NAND gates at the prescaler's output generate the separate UP CLOCK and DN CLOCK signals required by the 74192 decade up-down counters which follow.



This photo shows the methods used to mount the main logic and display boards. Note the direct wiring from 4 of the coax jacks to the multiplexer IC's inputs.

Note that the control flip flop (IC8A) changes state synchronously with the UP CLOCK output. This ensures error free operation when the count direction is changed, but requires some additional precautions in the unit's design and application. With this technique, the last up count that occurs should have been a down count. Unless corrected, the display will be 2 counts high. We correct the count in advance by starting it from -2 instead of 0 if there is going to be a down count.

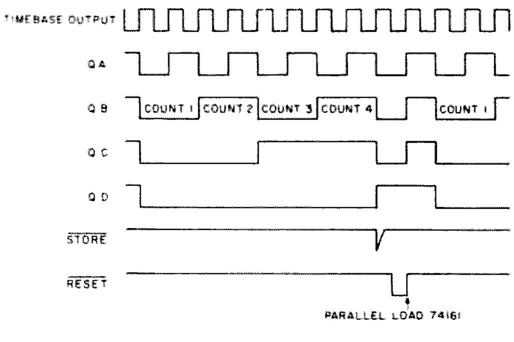


Fig. 5. Control logic timing diagram.

The unit assumes that if there is going to be a down count, then the fourth pair of counter inputs (labelled COUNT4 and DN/$\overline{\text{UP}}$4) will be set for a down count. It can only correct for a single change of count direction so ensure that all of your oscillators which require up counts are connected to lower numbered inputs than those requiring down counts.

Control Logic

The control logic provides the signals which cause the multiplexer to scan the four inputs, store the final count, initialize the counters, and start the frequency measurement cycle over again. Its operation is diagrammed in Fig. 5. The frequency of TIMEBASE OUTPUT should be at half the desired display resolution. It is divided by the 74161 (a 4 bit binary up counter) to control the multiplexer IC's "select" inputs. Qd of the 74161 is used as the count gate. It works by enabling (low) or disabling the multiplexer IC. The timing diagram shows that the frequency measurement cycle begins when a positive edge of TIMEBASE OUTPUT increments the 74161 to the all zero state. Subsequently, each count input and down-up control input is connected to the prescaler for precisely two periods of TIMEBASE OUTPUT. Qd then goes high, inhibiting further counts. This transition is followed by the $\overline{\text{STORE}}$ and $\overline{\text{RESET}}$ pulses.

$\overline{\text{STORE}}$ loads the received frequency count into the recirculating shift register memories that are part of the multiplexed display drive system and synchronizes them with the digit strobe circuitry.

$\overline{\text{RESET}}$ initializes the prescaler flip flops and sets up the 74161 for the next frequency measurement cycle. For reasons discussed previously, this signal is steered to CLEAR TO 0 or $\overline{\text{PRESET TO -2}}$ depending on the state of DN/$\overline{\text{UP}}$4 to initialize the main up-down counter.

Don't omit the RC network at the input of the 7410. It's needed to eliminate

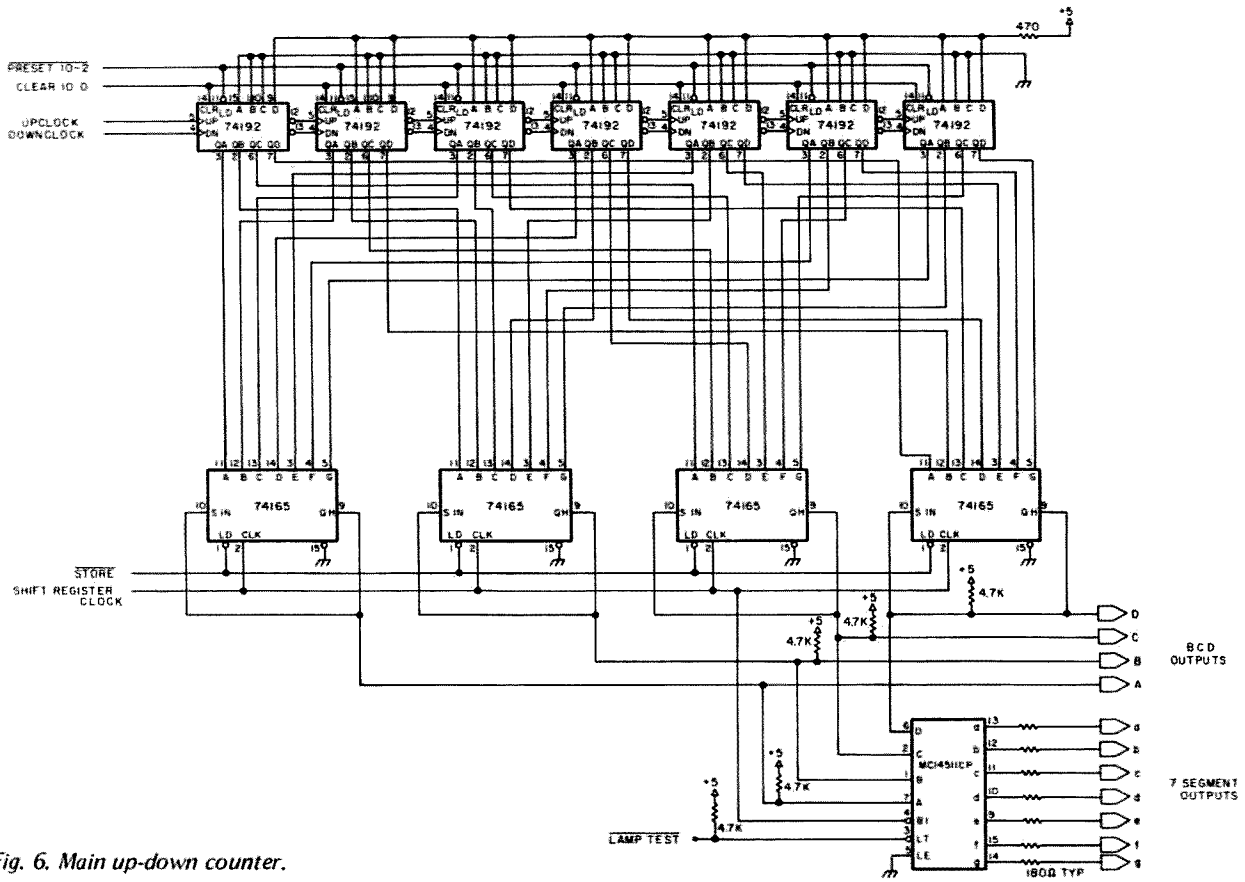

Fig. 6. Main up-down counter.

a glitch and adds to the delay provided for the last count to propagate to the final counter stage.

Main Counter

Seven (or as many as you want) 74192 dual clock up-down counters are used as shown in Fig. 6. Note that the clear function requires a positive pulse while preset needs a low going pulse. The data inputs of the counters are connected to represent 9999998 or -2 in BCD code. Their outputs are wired to the parallel load inputs of four 74165 8 bit shift registers.

Multiplexed Display Drive

Several advantages result from using a multiplexed display. These include minimum parts count, lower cost, fewer interconnects and lower power dissipation. With this technique it is often a simple matter to mount the display remotely in a window originally intended for a receiver's slide rule dial. The actual displays are easily wired up. Just connect like segments in parallel and run individual digit strobes to the common cathode or common anode of each digit. Radio Shack sells a universal multiplexed display PC board for this purpose which appears to be ideal for use with any of the larger LED digits.

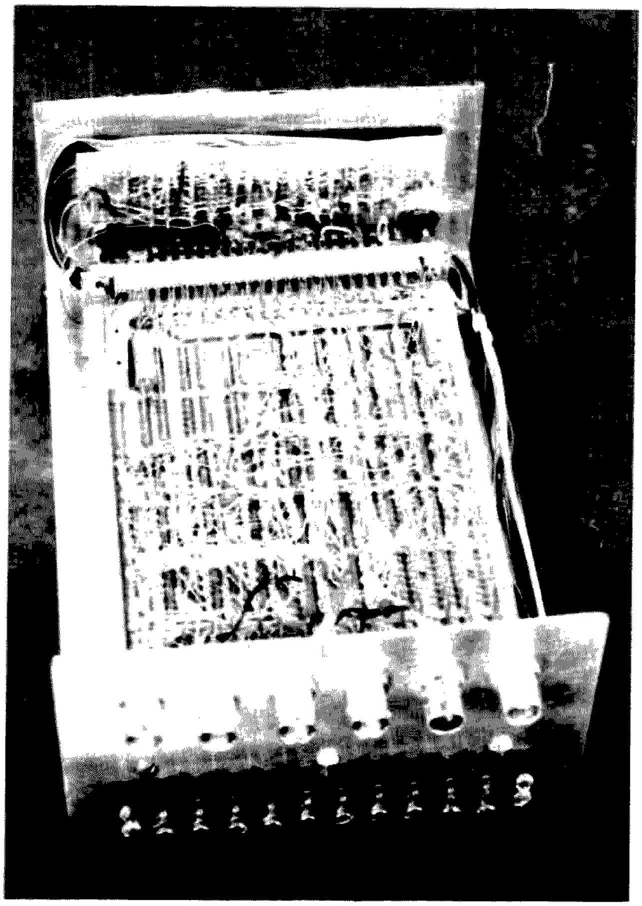
Using 8 bit shift registers for the display memory, rather than separate latches for each digit, helps keep the DIP count down. Data indicative of a received frequency is loaded into the registers shown in Fig. 6 by the STORE pulse at a 5 or .5 Hz rate depending on the resolution. Subsequently, each SHIFT REGISTER CLOCK pulse moves the data one place (actually one digit) to the right. The four bits for each digit appear in sequence, most significant digit first, at the inputs of the seven segment decoder driver IC and are recirculated by means of the serial inputs to the shift registers.

The digit strobes are generated in a fifth shift register, shown in Fig. 7. This IC contains a single "1" which is shifted down its length in synchronism with the received frequency data in the other shift registers. Simple buffers enable the "1" to turn on the LED digit corresponding to the data currently at the inputs of the 7 segment decoder/driver. High beta emitter followers with a pull-up resistor to +5 V at each shift register output will allow strobing of common anode displays. The buffer circuitry in Fig. 6 is for common cathode displays and features the use of an integrated digit driver. I'd better point out that for common anode displays you should change the 7 segment decoder to a 7446.

Interdigit blanking is incorporated by connecting SHIFT REGISTER CLOCK to the active low blanking input of the 7 segment decoder. This eliminates ghosting effects seen in multiplexed displays when one digit is not given sufficient time to turn off before the next digit is turned on. SHIFT REGISTER CLOCK can be as high as 10 or 20 kHz if necessary or convenient so display flicker needn't be a problem. Use a signal from the timebase divider chain that has a high duty cycle (a Qd of a 7490) for minimum loss in brightness due to the interdigit blanking.

Timebase

To operate the received frequency counter, we need a switch selected 5 or 50 Hz TIMEBASE OUTPUT signal



The rear panel connections are visible here. The coax jacks are for a direct input to a VHF prescaler, the 4 COUNTi inputs, and the 5 MHz frequency standard. The barrier strip is for power, count direction control, and outputs from the input selector switch.

as well as a SHIFT REGISTER CLOCK. To make the counter's resolution meaningful, these must be derived from a crystal oscillator of more than ordinary stability and accuracy. I chose a crystal oscillator frequency of 5 MHz for easy comparison to WWV. A cascade of 6 7490 decade counters yielded all of the required frequencies.

My timebase circuitry is shown in Fig. 8. The oscillator circuit is from an article by Kelley[1]. He described a circuit which employs a 4 MHz crystal and also provides all of the output frequencies we need here. A significant advantage of his circuit is that he made a circuit board available for it.

How important is timebase accuracy? It doesn't take much more than .3 ppm error at 30 MHz to cause a 10 Hz received frequency error. To obtain such accuracy you must adjust the oscillator to zero beat with WWV using a visual indication of zero beat, such as a Lissajous figure on an oscilloscope, or your receiver's S meter. The oscillator should be aged by at least a week's continuous operation with several hot-cold temperature cycles, then carefully temperature compensated. See Kelley's article for a good description of these procedures.

Power Supply

Thanks to three terminal voltage regulators, power supply design holds no mystery. The only problem is finding suitable components at reasonable cost. I spent less than $12 on the major power supply components at a local Radio Shack store. The received frequency counter requires 5 volts at at most 1.5 Amps. The transformer shown in Fig. 9 can supply twice that load. The second filter capacitor and regulator provide margin for powering the interface components and other equipment.

Construction

The major construction problem is how to interconnect all of the ICs. As discussed earlier, display and timebase PC boards are available. 21 other DIPs remain, plus whatever interface components you use. It's not too great a chore to use wire wrap or a similar technique using solder strippable enamelled wire for these interconnects. Indeed, if you're at all serious about experimenting with digital ICs, you shouldn't consider any other approaches. Economical alternatives to Gardner-Denver tools are available from Godbout Electronics. You can even make your own.[2] With wire wrap, you'll get your projects off the ground faster, be free to make changes at any time, and have an easier time debugging and troubleshooting because the ICs will be in sockets.

I make my own wire wrap boards by pushing the IC socket leads through holes in "P" pattern vectorboard. It's not necessary to solder them in place; the wrapped wires

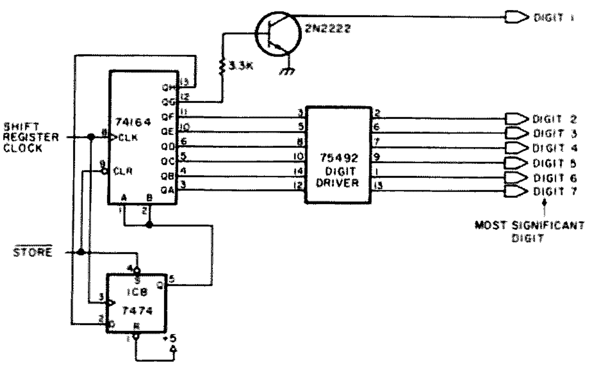


Fig. 7. Digit strobe circuitry for common cathode displays. Modification for common anode displays is discussed in text.

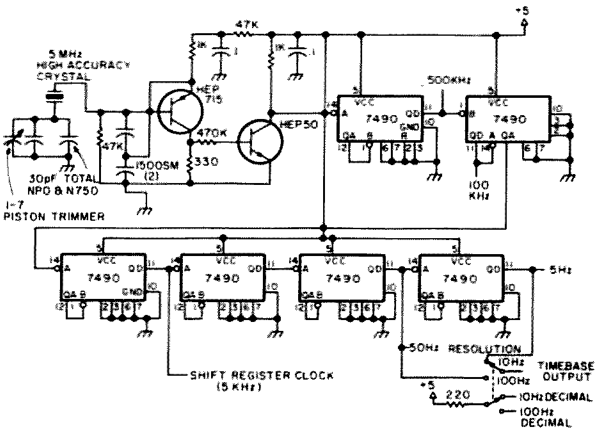

Fig. 8. Timebase schematic.

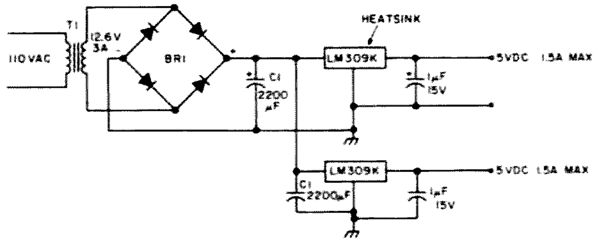

Fig. 9. Power supply. T1 – Radio Shack #273-1511; BR1 – Radio Shack #276-1146; C1 – Radio Shack #272-1020; heat sink – Radio Shack #276-1361.

will be sufficient to hold them in place. The leads of discrete components can also be pushed through the holes and wrapped to or soldered to other component or socket leads. Bus strips for power distribution can be fashioned from lengths of 3/8 inch wide, 1/16 inch thick double-sided copperclad board. These will just fit on edge between push-in terminals placed in alternate rows of holes in the board's grid at convenient tap-off points. The photograph shows the technique applied to a 8K x 8 bit dynamic RAM board. Hopefully, it will give you an appreciation for some of the details I've glossed over.

A word to neophyte wire wrappers: Limit yourself to 2 wraps per pin. Connect top wraps only to top wraps and bottom wraps only to bottom wraps so that entire chains don't have to be unwrapped in order to move a single wire. Keep your leads short and laid out neatly, but leave enough slack in them so that you can tug on one end of a wire and find the other end by noticing what moves when you tug. Avoiding mistakes is far easier than finding them, so be sure to pencil over each wire on the schematic as you put it in.

Packaging of the resulting circuit boards can be as simple or as elaborate as you choose. The woodgrain finished aluminum cases which became available too late for me to use seem ideal for this purpose. In my unit, separate display and counter boards are mounted at right angles to each other on adjoining chassis walls. The U-shaped chassis was bent up from a piece of scrap aluminum and a cover fashioned from a salvaged chassis bottom plate complete with ventilation slots. A can of blue spray paint and a silver on black escutcheon for the front panel added character to this most economical enclosure.

Checkout and Debugging

When you've got all the DIP sockets wired up, it's time to plug in the ICs, turn on the power and cross your fingers. Check each DIP with your fingertips. If one is painfully hot, it's probably defective. If it's more than ordinarily warm, it may have an output shorted to 5 V, ground, or another output. Don't jump to false conclusions here because counter and shift register chips run warmer than less complicated ICs.

After passing this "smoke test," it's advisable to check the power and ground bus noise levels. Greater than 200 mV p-p switching spikes or erratic operation that can't otherwise be explained may indicate a need for more power supply decoupling capacitors. You should use at least a 47 uF tantalum bypass where the power leads attach to the board and additional .1 uF disc ceramics for every 4 or 5 ICs. This will suffice for a low ac impedance power distribution technique such as that described earlier. Less ideal methods may require a .02 uF capacitor at each IC's power pins (except for the 7490s, the standard corner pins) for reliable operation.

Next, hook up and examine the display. With no COUNT inputs, you should be able to change the reading from 9999998 to 0000000 by grounding DN/UP4. Put in a signal of known frequency from the timebase divider chain and you should get a display that is correct to the last digit. Repeat this step with different frequencies and you can check out all of the main counter and display

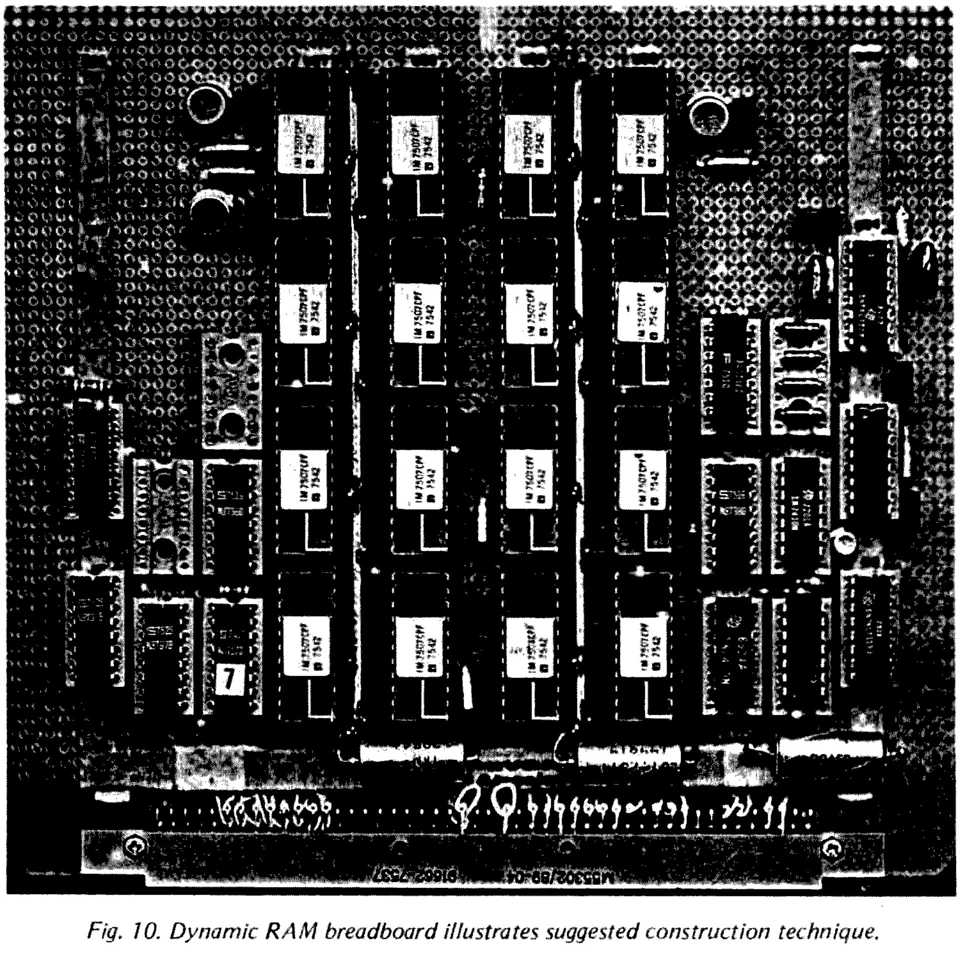

Fig. 10. Dynamic RAM breadboard illustrates suggested construction technique.

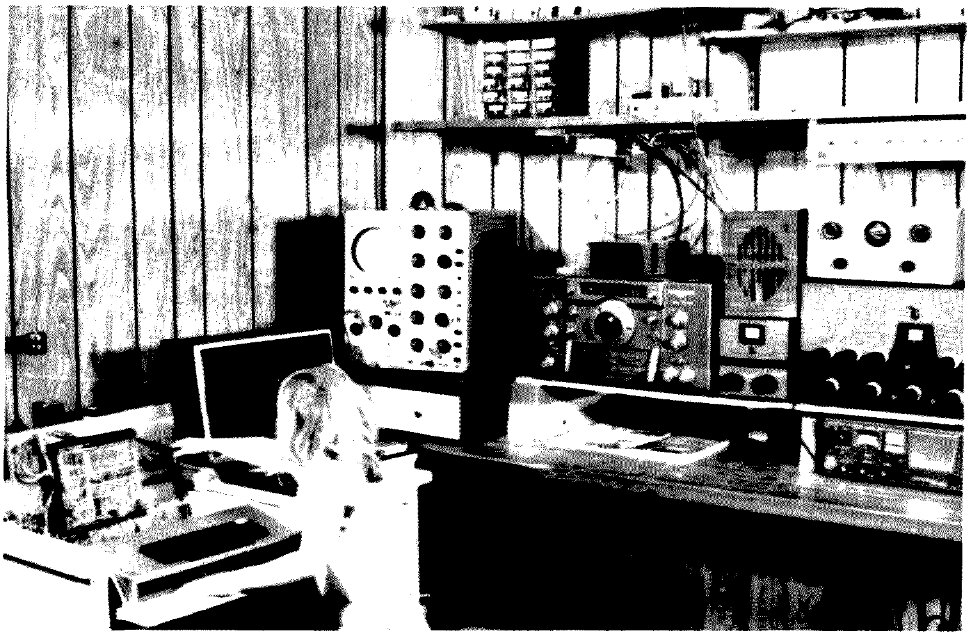
circuitry. Exercise each of the COUNT and DN/UP inputs and verify their proper operation. This will complete the checkout phase.

You can expect a problem or two during checkout. If one arises, try to isolate it to a functional circuit area. Check your wiring there and replace or swap any suspect ICs.

The control logic can be proved out by verifying its timing diagram given in Fig. 5. If you don't have a scope, substitute a debounced switch for the timebase output signal and measure the appropriate logic levels with a VOM or logic probe after each alternation of the switch. Measure $\overline{\text{STORE}}$ to the left of its coupling capacitor (CI in Fig. 4) so as not to be misled by its narrow width.

Most problems in the counter chain can be located by signal tracing. With a high enough input signal frequency, simply look for logic level transitions at the counter's Q outputs and at the interconnections between counter stages.

Many display defects can be diagnosed from their visible symptoms. A digit driver stuck "off" will blank its digit. One stuck "on" will cause its segments to glow with perhaps unequal brightness. Wiring errors between the segment driver and the segments or between the shift registers and the 7 segment decoder/driver will cause some numbers to be displayed incorrectly.



View of the station with a junior operator helping debug my microprocessor/TV display system. The .19" MAN 4 display LEDs on the received frequency counter are too small to be seen from this distance.

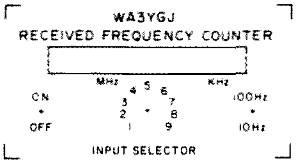


Fig. 11. Front panel screening artwork.

Conclusion

One must own and use a digital frequency readout in order to fully appreciate its value, so I won't expound on the subject. The received frequency counter is more complicated than a conventional frequency counter, but its added complexity adds more to its versatility than to its cost. It's not the simplest digital frequency readout available, but it's the only universal one I know of. To me, these points make it the obvious choice for construction by a radio amateur and I hope you agree.

All of the required ICs, with the possible exception of the Motorola MC14511CP and the Signetics N8T98B, can be purchased from *73 Magazine* advertisers. These two are readily available from their manufacturers' franchised distributors. In any case, I'm confident of being able to locate a parts source, so drop me a line if you have any problems.

I'd like to hear your comments on this article. If sufficient interest exists, a printed circuit board can be made available. ■

How Do You Use ICs?

-- part II

Alexander MacLean WA2SUT/NNN0ZVB
18 Indian Spring Trail
Denville NJ 07834

The 7400 gate is the workhorse oscillator IC. There appear to be more circuits using this one IC than any other. It would seem the logical one to begin with.

Its full name is quadruple two input NAND gate. As many of the ads will just list it as 7400 gate, let's leave it at that. You may also see it as SN7400N or something similar. The basic thing to look for is the number 7400.

This identifies it as the 7400 series of logic. This is the transistor transistor logic (TTL or T^2L) family you want to start working with. There are other devices in the 7400 family; it just happens that the first one, the 7400, is the particular one we want.

The name tells a few things about it. First it is a gate. A computer will make much of that, but for our use it's just an identifying name. There are four of them in the package. These are identical units. This is helpful. Helps account for all those pins.

It is a NAND gate. This is a specific digital logic function for a computer. At the moment it does nothing for us, so ignore it.

Its use as an oscillator was chosen to familiarize the experimenter with the 7400. In a frequency counter the device would also be used to perform various switching or signal routing functions. The device is also adapted for mixing, product detecting, and small signal amplification.

The oscillator circuits are more complex than many of these other uses, and easier to isolate and explain. Once the makeup of the device is learned, other uses and circuits with them should be no problem for you.

The first two questions are: Where does the voltage go and what are the other pin connections? Table 1 shows the various pin connections.

Voltage is simple. Pin 14 is the Vcc pin and gets the five volts regulated. Pin 7 is the ground connection. This stays the same for all circuits using the 7400 gate.

Each of the sections has an output pin. The output is between that and ground. The input, naturally, is between the input pins and ground. Here we have a slight problem, and embarrassment of riches, so to speak.

There are two input pins to each section. This is not just an oversight by the manufacturer. They are supposed to be there, but it can be a problem in some circuits.

The oscillator circuits seem to be quite tolerant in many respects. One of the simplest is shown in Fig. 1[1]. This type of oscillator uses two gate sections.

As all of the sections are identical, it makes no difference which two are used; however, physical layout may suggest using two on the same side of the IC package.

In this oscillator circuit, both input pins of each section are tied together. Usually one of the extra sections of the IC is used as a buffer for the oscillator as shown. Here too the extra input is tied to the other.

Fig. 2[2] shows a similar circuit. In this one the extra input is left floating. Notice that the crystal and the feedback capacitor have changed position in the circuit. A trimmer capacitor

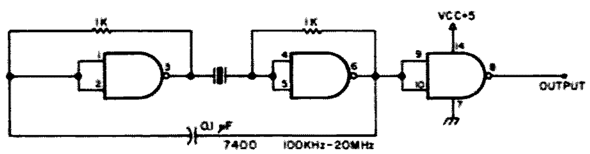

Fig. 1.

has been added to alter the crystal frequency. Notice also that the values of the two resistors are different.

There are a number of circuits which are quite similar to these two. From inspection it would appear that the circuit will operate over quite a wide frequency range. A trimmer capacitor may be added to change the crystal frequency, and the value of R1 and R2 is not too critical; values between 220 Ohms and 2.2k Ohms were common.

The original plan was to compare the performance of the various circuits and gather more definitive data about the operation and tolerances of the circuits.

Unfortunately, I quickly learned something, which none of the articles mention, that has a direct bearing in experimenting with IC oscillators.

WARNING: Testing IC oscillators can be extremely hazardous to your health! In all of the bench testing of experimental oscillator or other circuits I have done, I have never found any that caused as much or as severe TVI as IC oscillators.

Just the one little circuit powered by a transistor radio battery was enough to obliterate Walter Cronkite. It completely took out almost all stations, both sound and picture.

This meant that there was to be very little actual testing, and that confined to the more obscure hours. However, some data was obtained.

To understand why there was so much TVI, it is necessary to go a little bit into the theory of what the circuit is doing. Normally when you build an oscillator, you are trying for a sine wave output as free from harmonics as possible.

The IC oscillator is not actually an oscillator at all. The nearest thing to it in tubes would be the multivibrator circuit. It is not actually oscillating, but switching at a rate determined by the crystal. The digital ICs were built for switching purposes, and this is an adaptation of their ability to switch at high speed.

The output is a form of square wave. It may not even be a pure square wave at that. What this means is that it is very rich in harmonic content. Also, the harmonic content is at about the same level as the fundamental.

The 7400 is supposed to be guaranteed to 20 MHz and the harmonics go even higher. The lower the initial frequency, for example, 100 kHz, the worse the TVI. There are so many subharmonics.

Using a higher frequency crystal helps slightly, but there was still awful trouble with a 3 MHz crystal. As far as a TV set goes, the interference is the worst on the lower channels and seems to drop off slightly with the higher channels.

Another fun thing about ICs is that they love to oscillate all by their lonelies. Take out the crystal and the circuit still oscillates and still generates TVI.

It was not possible to determine the frequency at which this was going on, as the oscilloscope wouldn't show it. This too is something of a problem. The 100 kHz oscillator used did not show the correct pattern on the scope. It appeared that there were so many subharmonics present that the trace could not be stopped to show just the fundamental.

This IC horror story has a slightly happy ending. In actual use there may not be too much trouble with them. The basic factor in the TVI problem occurs in testing. Any meter or scope lead looks like an antenna and the thing takes off.

They also have a tendency toward some form of spurious oscillation along with the desired one. Be generous with the bypassing. The test circuit bypassed both the input and the output of the regulator and, at the same time, the IC Vcc pin.

The IC seems to find the signal it wants in all that mess. The later divider circuits seem to function at the correct frequency. It just looks like testing is going to be trouble. The test leads themselves are going to broadcast the crud.

The problem with the oscilloscope might be solved by using a triggered scope. Then the waveform might hold still for viewing.

When the test circuit was set up inside a shield, the TVI problem disappeared. All well and good, but it may still be a problem when any cable is connected to the output, for example, of a frequency standard. You may still be broadcasting harmonics to more than just your receiver.

This should also be kept in mind for inside the equipment. While the IC seems to respond to the desired frequency, there may be many spurious signals generated that will be floating around inside of the IC equipment.

The square wave is inherently a harmonically rich signal. While the specific IC it connects to may not be affected, a stage designed as an rf amplifier or other linear signal handling stage may respond to this as easily as to the desired signal coming in from the antenna.

Be prepared for TVI problems if you are going to do much testing of circuits before you use them. ICs are such that there should not be too much need to test or experiment. If the circuit is in use in a similar piece of equipment, it should be what you need for your equipment and will probably work as well.

The two circuits shown so far are quite similar in configuration. A somewhat more complex type of circuit is shown in Fig. 3[3].

Instead of the two

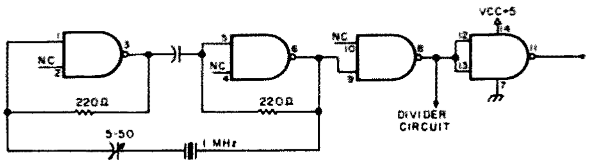

Fig. 2.

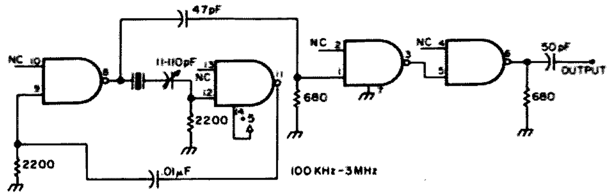

Fig. 3.

resistors being between input and output of the two sections used, the resistances are between gate input and ground.

The oscillator output is capacitor coupled to the two section buffer stage. The buffer input gate has a resistor to ground and the buffer output stage is resistively loaded and capacitor coupled.

This is another wide range circuit with a trimmer capacitor to change the crystal frequency. The only part which seemed to be critical was the 47 pF oscillator coupling capacitor. Other values around it worked, but not something like the .001 or .01 values used in some of the other parts of IC circuits.

Fig. 4[4] shows a circuit similar to Fig. 3. Here the gate outputs are connected to the Vcc pin through equal resistors. Another difference is the direct connection between the input of the first gate and the output of the second. The feedback (?) capacitor in this circuit goes to the Vcc pin. Notice the change in the usual value for this capacitor and the addition of the 150 Ohm resistor between the input and output of the second section.

The tolerance of this capacitor, while not critical, is not as broad as with some other circuits. The oscillator output is directly coupled to the following buffer stage.

While in detail these circuits do have differences in their configuration, an overall view shows that they are more similar than different. They have a number of features that are almost the same for all.

This allows us to generalize a bit about IC oscillator circuits, which will help to simplify them and make them more easily understood by inspection of the schematic.

The most common IC oscillator circuits use two gates for the oscillator section. The remaining gates are often used for buffers.

With the 7400 oscillator, it is common to leave the unnecessary gate input of each section floating. The two gate inputs may also be tied together.

Each gate section of the oscillator has a resistor of equal value. This may be between each gate input and its output pins, between input and ground, or between output and ground.

There is usually some sort of feedback or coupling capacitor of a value of .01 to .1 uF. The output of the oscillator is usually either directly coupled to the buffer stage or is capacitively coupled.

They normally operate over a wide frequency range and most circuits show a trimmer capacitor in series with the crystal for minor adjustments.

There are, of course, variations in the circuits. However, by the time these normal features are noted and looked for, what little remaining that is abnormal will be easily spotted and understood.

By thinking of these circuits as sections of this IC, it will not be long before you can recognize and place any sort of IC oscillator circuit of its type.

One thing to remember is that the circuits use two gate sections. The 7400 is a NAND gate. There are other gates that will also work and other families of ICs which will also work. The circuits will be much the same in configuration and the parts values will be similar.

There are circuits shown that are able to operate with one gate section instead of two. These should not be a problem to understand, as they are as simple as the others.

There was one example, Fig. 5[5], of a circuit that returned several of the unused gate inputs to the Vcc source pin. One gate input was used as a switch to turn the oscillator on and off by connecting or disconnecting to the Vcc source. This does not appear to be common, but it obviously can be done and might fit some requirement you have.

You will also see circuits drawn with the rectangular shape of the unit instead of the section symbols. All this requires is a look at the pin chart to figure out what goes where.

By now you should have little trouble redrawing the circuit in Fig. 6[6] to the sectionalized symbols and seeing how it resembles other circuits.

Which schematic representation is used depends on how the IC fits into the whole equipment. If it is sectionalized so that one gate may be applied to another circuit, it is more common that it be drawn that way and the sections labeled U1A, U1B, etc.

If the IC is completely used by the particular section of the equipment, it may take less schematic space to draw it as a rectangle and just put the pin numbers around the edge. There is no hard and fast rule.

The nice thing to remember is, for the most part, that you can take any of these circuits and simply drop them into the place you want them in your own equipment, with a high degree of certainty that they will work.

This leads to the next logical question: What if it doesn't work? Another nice thing about ICs is that the low voltage level and the general simplicity of the circuit make troubleshooting easier.

If you duplicate a known circuit you should have no trouble, but if you are making parts substitutions you may have to cut and try a bit.

If it doesn't work at all, the first thing to check is the supply voltage and then the wiring. Be sure you read the IC pins correctly and got the components to the right terminal.

If that isn't it, try varying the feedback capacitor value above and below what you are using. The next step would be to change the resistor pair to a higher or lower value. Be sure it is enough of a change to make a difference.

Testing the circuit

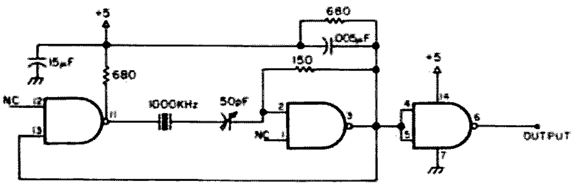

Fig. 4.

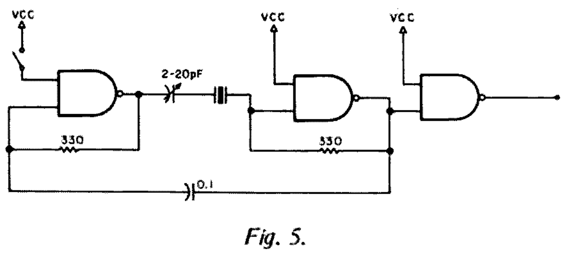

Fig. 5.

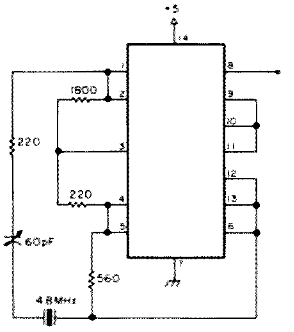

Fig. 6.

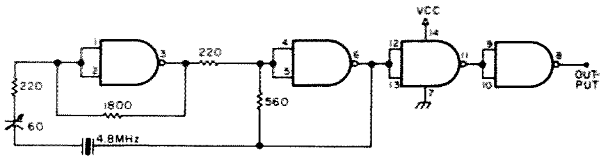

Fig. 7. (Fig. 6 redrawn.)

outboard is one way to get the bugs out. You might have a defective IC section which is easy to test by substitution before you solder the IC in. Sockets can be very handy.

It might be the crystal. Normally IC use will not damage a crystal, but some crystals are more active than others. Try another crystal in the circuit. The 7400 is designed for 20 MHz or lower so don't expect a high frequency overtone crystal to work well.

While you are breadboarding, it is not that hard to try one of the other circuit configurations. That might just solve the problem.

One of the more easily noticeable problems is a slow starting oscillator. If changing the crystal doesn't make a difference, it is most likely a question of wrong parts values. In this case, the resistances should be varied, although it might be the feedback capacitor.

As TVI is a problem, testing will have to be brief. IC oscillators are not shy about telling you if they work. A triggered scope would be the first choice, but any scope will show if oscillation is taking place, if the frequency is not too much higher than the scope will show.

You should be able to hear it on a monitor receiver, and it probably will show on your TV set. The TV set won't tell you if it is the correct crystal frequency or self-oscillation, though.

Most of the IC oscillators are designed for clock, counter or other continuously running circuits. You may have to experiment to find a circuit that works well when keyed fast, such as one used for a CW transmitter. Here the monitor receiver is first choice. If it sounds OK locally, it will probably work in the finished circuit.

With the circuits tried, it was hard to find one that wouldn't work over a wide range of parts values. Individual requirements would suggest some testing to see that all conditions are met by the oscillator before installation.

When the unit is finished, it's a fine time to find out that the oscillator won't key properly or doesn't work at all. ■

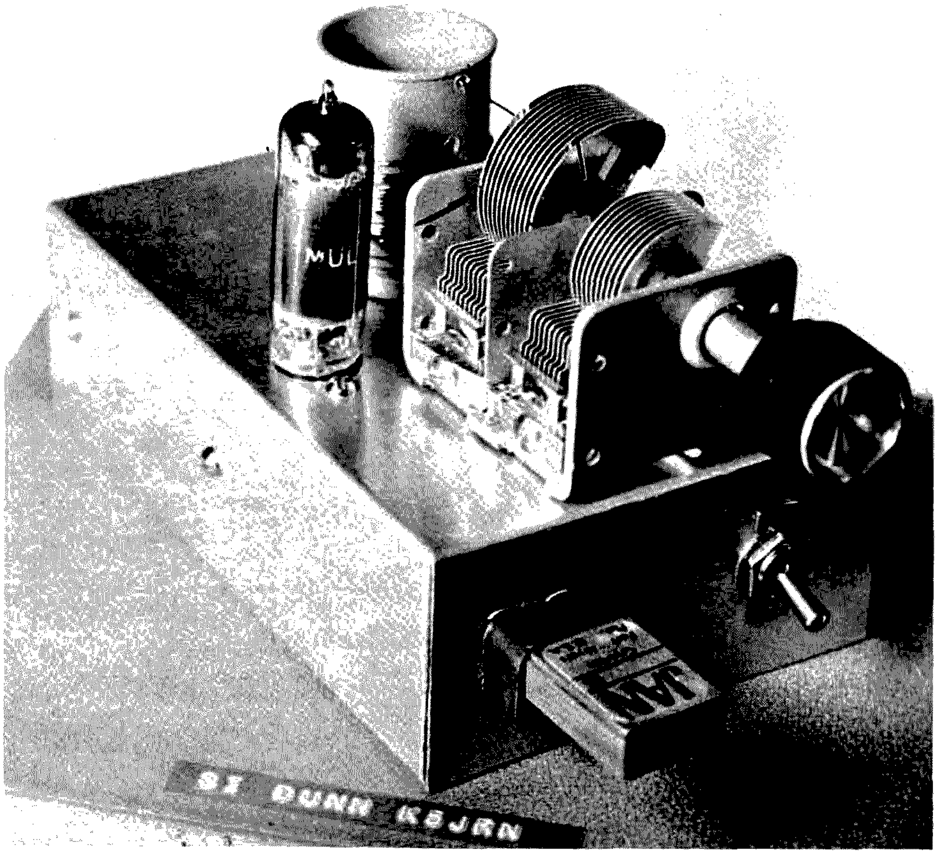
QRP Fun on 40 and 80

-- have a real ball with just 5 Watts!

Si Dunn K5JRN
3607 Binkley
Dallas TX 75205



Nostalgia can do funny things to a ham. Recently, I recalled the one tube transmitter that first got me on the air as a Novice back in 1957. And before I knew it, I was doodling a schematic and looking through my junk box for parts to build a similar rig.

My first 6AQ5 oscillator was quite a peanut whistle. It put out enough rf to burn out the flashlight bulbs I link-coupled to the tank coil for tune-up. And that was enough power to work all states and some DX on 40.

The transmitter described in this article has several applications: (1) its circuitry is simple, so many beginners and "appliance operators" should be able to build it and get it on the air in a matter of hours; (2) its 4 to 5 Watt

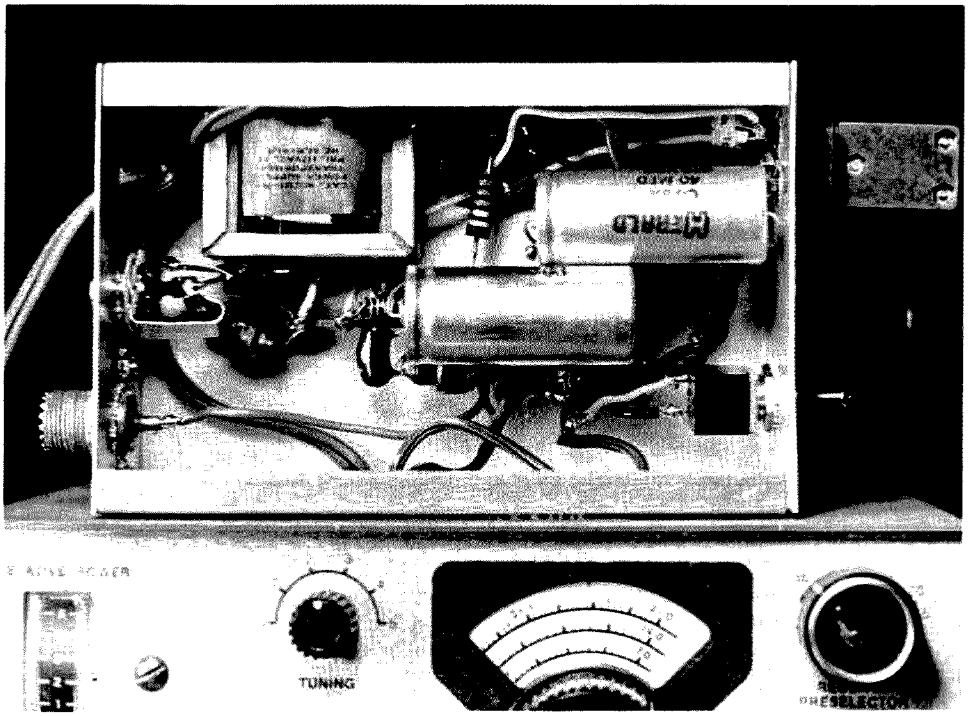
input is ideal for QRP work; and (3) it's cheap – a good parts scrounger can build it for a few bucks at most. Even if everything has to be purchased new, the cost can be kept below $20.

I built mine straight out of the junk box and had it on the air in five hours, including the time spent in drilling and filing holes in the 4½ x 6½ x 2 inch aluminum chassis. Parts layout is not critical, but a beginner building his first rig might want to use a slightly larger chassis.

The power transformer used in this rig is rated at 15 milliamperes continuous service. However, I've experienced no difficulties while drawing 20-25 milliamperes on CW. Naturally, the key shouldn't be held down for more than a few seconds at a time while tuning up. A transformer with a slightly higher voltage and current rating could be substituted, with a corresponding increase in input power.

My third "CQ DE K5JRN QRP" brought a 579X report from a 500 mile daylight hop on 40 meters. Since then, this rig has given me hours of operating pleasure and many fine QSOs. A good antenna is desirable, but my dipoles are only 8 feet high.

While simpler transmitters can be built, this one is just about the bare minimum: no VFO, no meter and no bandswitch. Crystal control requires a bit more patience than VFO operation, but plenty of contacts can be made with just a couple of "rocks." With Novices now able to use VFOs, crystals can be picked up dirt cheap at hamfests and surplus stores.



Tune-up is simple. Connect the rig to a dummy load or to a 50 to 75 Ohm antenna. Temporarily slip a two turn link soldered to a 2 volt flashlight bulb over the tank coil, and tune for maximum brilliance. The full wave voltage doubler circuit delivers about 200 volts under load, and the 6AQ5 plate draws 20 to 25 milliamperes (four to five Watts input).

Tune-up also can be accomplished with a field strength meter, if you have one, or with the forward scale of an swr bridge. If you really want to get fancy, you can add a 0-50 or 0-100 milliampere meter between RFC2 and the B plus.

The plastic form for the tank coil is one and a quarter inches in diameter. I used a film container from a roll of 35mm Kodak film. A cardboard tube also would work, and so would a piece of broomhandle. A good home brewer makes do with what he's got. Don't be afraid to substitute parts of nearby values for the ones in this circuit.

The tank coil – 15 turns of #22 enameled copper wire – and the 365 pF variable (C2) resonate both on 80 and 40 meters. Care must be taken not to double an 80 meter crystal to a frequency outside the 40 meter band. Eighty will appear with the variable's plates meshed about 80 percent, and resonance on 40 will be with the plates about 40 per cent meshed.

Trimmer capacitor C1 is adjusted for best keying characteristics while listening to a harmonic of the transmitted signal.

Early morning is my favorite time for QRP work. At 5 or 6 am, many frequencies on 80 and 40 are

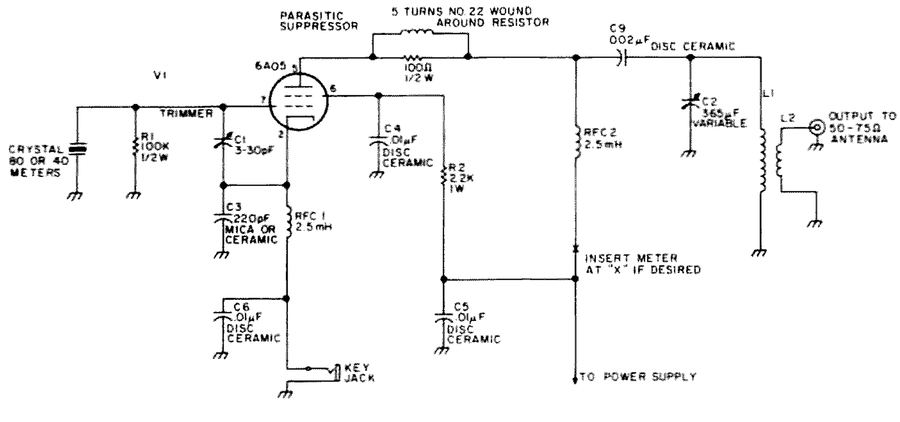


Fig. 1.

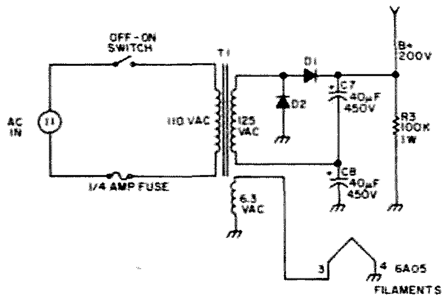

Fig. 2.

clear of signals and the skip is good for low power DXing. A short CQ and "QRP" usually results in a contact and a query: "How much power you running, OM?" ■

Parts List

Xtal – 80 meter or 40 meter fundamental crystal (Jan Crystals, 2400 Crystal Drive, Ft. Myers FL 33901)
R1 – 100,000 Ohm, ½ Watt
R2 – 2,200 Ohm, 1 Watt
R3 – 100,000 Ohm, 1 Watt
C1 – 3 to 30 pF trimmer (or similar value)
C2 – 365 pF broadcast band variable capacitor
C3 – 220 pF disc ceramic or mica
C4,5,6 – .01 uF, 600 volt disc ceramics
C7,8 – 40 uF, 450 working volt electrolytic capacitors
C9 – .002 uF disc ceramic, 600 volts.
RFC1,2 – 2.5 millihenry rf chokes
Parasitic suppressor – 5 turns #22 wire wound around 100 Ohm, ½ Watt resistor
L1 – 15 turns #22 enameled wire on 1¼ inch plastic form
L2 – 3 turns insulated hookup wire wound around cold end of L1
T1 – 110 V ac primary, 125 V ac 15 mA, and 6.3 V ac secondaries (see text)
D1,D2 – 800 PIV silicon diodes
V1 – 6AQ5, 6AQ5A or equivalent

CONTESTS

from page 11

Zone Map, DXCC country list, WAE country list and WAC boundaries are standards for the contest. QSO points are as follows: 3 points for QSO with station on different continent; same continent but different country counts 1 point, except between NA stations, which counts 2 points; contacts between stations in same country count 0 points per QSO. Final score is the result of the total QSO points multiplied by the sum of zone and country multipliers.

AWARDS:

Various certificates, plaques, and trophies will be awarded, and all scores will be published in *CQ Magazine*.

ENTRIES:

Logs must show all times in GMT, and use separate sheets for each band. Indicate zone and country multiplier only the first time worked on each band. LOGS WILL BE CHECKED! Each log must be accompanied by a summary sheet; official logs and summary sheet are available from *CQ* for a large SASE. All entries and requests for logs should be addressed to: CQ WW Contest Committee, 14 Vandeventer Avenue, Port Washington NY 11050.

SPECIAL EVENTS STATION WW9WWW

The Sheboygan County DX Association will once again operate special events station WW9WWW during the period from 0000 GMT, 12 September, 1976, through 2400 GMT, 18 September, 1976, in observance of Wonderful Wisconsin Week. Operation will be all bands 80-10, CW and SSB, on or close to the following frequencies: 3550, 7050, 14,050, 21,050, 28,050, 3810, 3910, 7175, 7280, 14,215, 14,285, 21,300, 28,550. QSL via WA9UEK, P.O. Box One, Plymouth WI 53073 USA. SASE or SAE and 2 IRCs is an absolute *must* for those wishing QSL.

CORRECTIONS

"A Test Lab Bonanza – using a transistor radio," WA7SCB, *73*, September, 1976, pages 64ff.

- page 66, column 1, line 13 should read, "as 1.5, 5, 9, etc."
- page 67, column 2, line 18 should read, "19 and you will rejoice when".

WORKED ALL MANITOBA AWARD

The Worked All Manitoba Award will be issued for confirmed contacts with amateur radio stations in specific numbers of Manitoba municipalities, local government districts, provincial parks, forest reserves, and national parks in the following classes: Class E = 50, D = 75, C = 100, B = 125. A special honor plaque will be issued for Class A, all 134. All contacts must be made after January 1, 1976. Record book, application forms, maps, rules, and conditions are available for a $1.00 fee from: Doug Bowles VE4QZ, 1104 First Street, Brandon, Manitoba, CANADA R7A 2Y4.

WORKED ALL MASS COUNTIES AWARD

Submissions must include a log listing dates, stations worked, mode and frequency. No QSL cards required. All QSOs valid including contacts through repeater stations. Station worked must be operating from county claimed. Log must be signed by another amateur certifying that the applicant has made the contacts claimed. Awards will be issued for a single band or mode if requested. A self-addressed stamped envelope must be enclosed for the return of the award. Submit logs to WR1ACT, South Shore Repeater Association, Box 284, East Milton MA 02186.

The Hybrid Quad

--has low windload, expense, hassle

The hybrid quad is a little used, little discussed antenna design that has been largely neglected by the ham community. One reason may be the lack of data available from the various texts covering antenna design. Over the past few months, the number of amateurs that have shown interest in the antenna, and the requests I have received for the specifics of its construction, have given the incentive for writing this article.

It must be noted that the design I chose is not the only possible combination in an antenna of the hybrid quad design. I do feel that the rewards of building and operating with my particular antenna demonstrated to others and myself its particular qualities over other two element arrays, especially for those amateurs looking for performance on a budget. My antenna, complete and ready to use, cost under 150 dollars. This included all hardware, coax, rotor, and a ten foot tripod.

The parameters for the basic layout are determined from studying the important characteristics of the full wave loop and the half wave dipole in their individual arrays. The spacing for the elements, especially the determination of using a reflector instead of a director, came from design characteristics of the two element yagi array. The feedline impedance and connection is that of a full wave loop array. The ARRL *Antenna Book* furnishes these basics.

Description

The true advantages of the full wave element are realized when used as a driven element. Through comparison, it was found that the noise level is lessened while signal level increases over that of a dipole. The feedline of a quad may be directly connected without any matching devices. At my QTH, it was easy to make the one and only length adjustment, from the peak of the roof that the tripod is mounted on. The only test equipment needed is an accurate swr bridge. The loop makes an excellent match to RG-11/U. Judging from the standing wave, demonstrated in Fig. 2, the two element array interacts for a feed match impedance of approximately 70 Ohms.

In all probability, the two element quad will outperform the hybrid version. There are two reasons for the design compromise. The first is cost. When working out the original parts list, I found it was far costlier to make the reflector a full wave loop. The weight would increase. The balance point would also have to be changed, and in doing this the windload of the antenna would increase dramatically. The result – the necessity for much heavier hardware, boom, and a heavier duty rotor. All of this adds to the cost of the antenna. The second point to mention would be the added fragility of the full sized quad versus the hybrid quad.

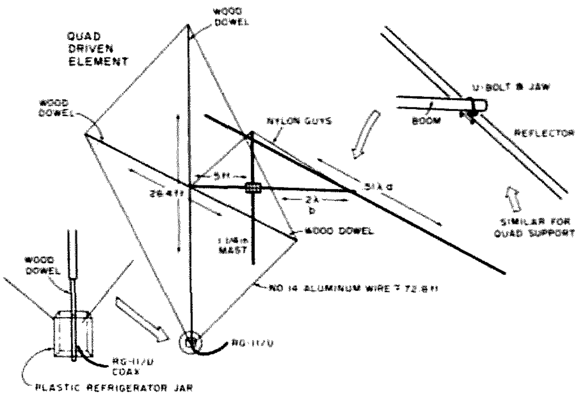

Fig. 1. a = 36', b = 13.85'. L = 1004/f(MHz). Note: Must be trimmed for lowest swr.

Due to the probability of ice and heavy rainstorms, the quad is best built in the diamond configuration. The entire structure, including the boom, is assembled from lightweight aluminum. 1¼ inch tubing is used for the boom and mast sections. The quad supports and the reflector element are made from telescoping 1 inch to ¾ inch tubing. The wire for the driven element is number 14 aluminum. The insulators are wood dowels treated with lacquer for waterproofing. They are inserted into the ¾ inch tubing ends and clamped down.

Construction

The two pieces that make up the quad structure are

Sgt. Ralph J. Volpe USAF WB8VCS/5
3333 Weir Ave., Lot #10
San Antonio TX 78226

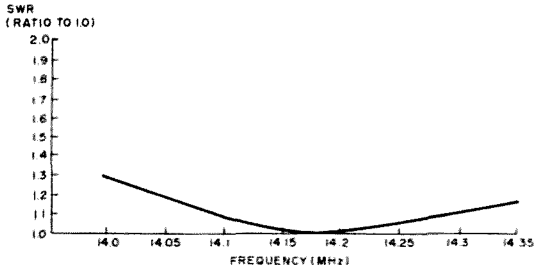

Fig. 2. Hybrid quad standing-wave chart, adjusted to 14.175 MHz.

made from telescoping aluminum sections to an approximate length of 26 feet. This can be accomplished by using a twelve foot tubing of 1 inch diameter. Into this tube you insert a section of 7/8 inch tubing. Finally, a 3/4 inch tubing can be inserted and all three adjusted for the appropriate length. Adjustable clamps used for plastic pipe can be used to make fast the sections of aluminum. See Fig. 3. The wood dowel insulators are telescoped into the end openings and clamped down. Small diameter holes are drilled in the wood dowels. The wire element is threaded through these during final assembly.

The reflector is similarly constructed. The ends of the reflector are capped with plastic furniture leg caps of appropriate size. The reflector is adjusted for the proper length and balance, then drilled in the center of the 12 foot section of 1 inch tubing. A TV type U bolt with jaw is inserted and fastened to the boom, as are the cross sections of the quad structure.

The measurements given are for 20 meter operation. They can be easily scaled for another band. If a director is used instead of a reflector, the actual spacing will be more critical. A director arrangement will show slightly more gain at its design frequency, with a more restricted bandwidth. Being more interested in ease of construction and total bandwidth, the director is ruled out and dimensions are calculated for a reflector.

A total spacing of .2 wavelengths with a reflector length of .51 wavelengths will give the best forward gain with an acceptable front-to-back ratio over the entire band, with the design frequency around 14.175 MHz. The actual gain of the array figures at 7.1 dB over a half wave dipole. This includes the gain of the full wave loop over a dipole as a driven element. The front-to-back ratio approximates 14 dB with the front-to-side ratio much larger. The Q of the antenna approximates 4.7.

The boom is made of 1¼ inch tubing 14 feet in length. As this will show some sagging, a strut type support is used from the mast to absorb the excess strain. The boom to mast bracket can be fabricated from a piece of aluminum stock with TV type U bolts and jaws. The mast is extended beyond the boom by 4 feet and nylon guys connect the elements at the ends of the boom.

A length of 36 feet is used for the reflector. The spacing from the driven element is 13.85 feet. This element should be tightened down while the array is on the ground.

For 20 meters, a length of 74 feet can be used for the wire loop for a start, trimmed for the appropriate operating frequency. If 14.175 MHz is used as the center frequency, the curve for standing waves will be very similar to the one shown in Fig. 2. The use of a 1 to 1 balun could be used to further balance the currents and flatten the swr. RG-11/U will match directly to the quad. The transmission line should be connected to the lower corner of the diamond. A plastic refrigerator container was used on my antenna to enclose the antenna to transmission line connections. A homemade toroid balun could also be enclosed in the container. If the builder would rather use 50 Ohm coax, an appropriate matching section could be employed.

The mast is connected more toward the quad element to balance the weight and windload on the antenna. A distance of from 4-6 feet may be determined by trial and error.

Operation

The moment of truth has come. The questions that arise are numerous; most can be answered by examing the reasons for its construction:

For simplicity and efficiency sake, the single band design is used.

Total cost of antenna materials and installation.

Efficiency and low angle of radiation at lower heights above ground; one specific advantage of the quad over the dipole.

A low Q design for a broad bandwidth for full twenty meter operation without prohibitive standing waves at band edges.

Possible ice and wind damage had to be considered in the structure design.

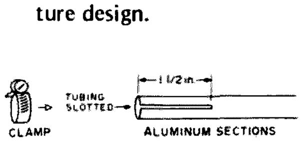

Fig. 3.

The design, construction and adjustment had to be within the capabilities of any simply equipped station.

In operation I have noticed the specific characteristics of the antenna. There is an excellent front-to-side ratio, of an average 30 or more dB in attenuation. This has been verified in reception and transmission. The front-to-back is more difficult to determine. The farther away the other QTH, the more noted is the directional attenuation. Averages range from 12 to as much as 20 dB. When short skip conditions are in effect, the front-to-back is noticeably less. Although I can only suppose, I feel this is due to a plain distance effect between the quad element and the reflector at varied radiation heights.

Conclusion

I work many DX stations with 30-100 Watts SSB. The reports I received from these amateurs are quite favorable. In the states, my signals are compared with those of stations using the full power limit. With 1000 Watts PEP I can very successfully compete in most of the DX pile-ups. My antenna is at a very modest height of 32 feet. The rotor I have been able to use without problem is an old TR-2.

I will not try to compare this antenna with those of larger design and complexity. My main desire is to open some thought to an antenna design that may be very useful to the do-it-yourself amateur. If you want an antenna that performs very well at low heights, is very efficient, easily built and adjusted, demonstrates exceptional directivity and broadbandedness, and all this at a cost most of us on a budget can afford, you may find this an antenna to strongly consider. ■

Frequency Detector for Your Counter

-- sounds alarm when set frequency occurs

Now that you have spent a small fortune on LED readouts, ICs, and assorted goodies, and countless hours to build that frequency counter, it is time to create another valuable addition for that basic tool.

What we are about to describe is an inexpensive device that will detect any frequency that your counter is able to display and activate an alarm of your choice (horn, gong, etc.). Even if the selected frequency occurs for only a fraction of a second, this device will trigger and lock until reset manually. The frequency desired is set with the use of inexpensive *decimal* (not BCD) type thumbwheel switches. Enough switches must be employed so as to cover the number of digits in your counter. In this manner, the desired frequency can be pre-dialed to the last cycle.

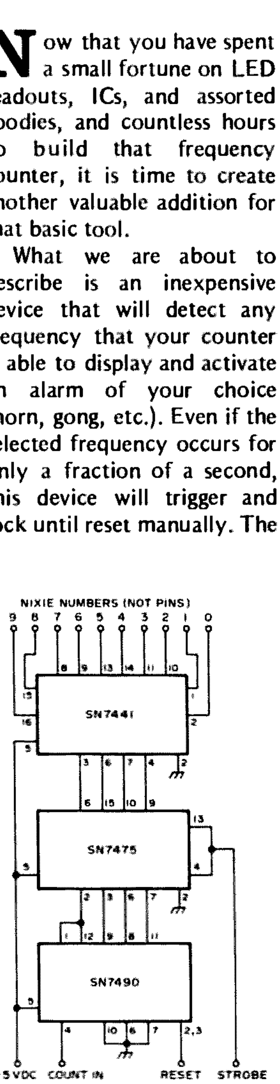

Fig. 1. Typical counter stage.

Even if the thumbwheel switches are not available, common garden variety single pole multi-position rotary switches can be pressed into service for this device.

When you are using your frequency counter to measure a transmitter VFO frequency or output frequency, an alarm such as this can be used to provide indication of an amateur band edge. Not only this, but a specific frequency can be "switched up" without even having to look at your counter or VFO dial, and the alarm will sound when you have arrived at the preset frequency. This feature would lend itself nicely for use by blind amateurs. By cutting a small notch in the "0" thumbwheel, the digits of the switch could be counted mentally by clicks until the desired digit was selected. This would make the average frequency counter usable by the blind, as he could "hear" the dialed frequency. In fact, a counter *without readouts* could be constructed for the blind amateur.

This device may be used with gadgets such as digital thermometers, clocks, etc., as an alarm. It is necessary only to have a BCD (binary coded decimal) system driving decoders for your particular type of readout. The conventional counter uses a 7490 decode counter driving a 7475 quad latch, which in turn may drive a 7441 (Nixie decoder) or a 7446 (7 segment decoder). The binary data may be taken from either the binary (BCD) output of the 7490 or the 7475. In some counters (el cheapo type), the 7475 memory is eliminated and the 7490 drives the 7441, etc., decoder directly. In these cases, the BCD information must be sampled at the 7490 BCD output. When the 7475 is included, sample at the 7475 latch BCD output. A typical counter stage is illustrated in Fig. 1. The BCD sample points are shown for both types of counters, with and without the 7475 latch.

Now that you have determined at what point BCD sampling can be made, it is necessary to obtain as many SN7441 Nixie decoder/driver ICs as your counter has digits. In other words, if you have a six digit counter, six 7441s must be used. Each decade of your counter will provide BCD data for each 7441 decoder. The 7441 decoder has a BCD input and 0-9 output. This integrated circuit translates the BCD incoming data to decimal notation by grounding the appropriate 0-9 pin. Basically what you are doing is adding an additional decoder separate from the one that is presently driving your readouts.

Rather than to feed a readout with the 7441 new

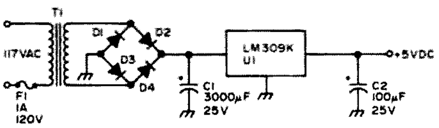

Fig. 2. Power supply. C1: 3000 mF, 25 V. C2: 100 mF, 25 V. D1-D4: 1N4002 silicon diodes. F1: 1 A, 120 V fuse. T1: 120 V ac to 6.3 V ac, 1 A filament transformer. U1: National LM309K 5 V regulator.

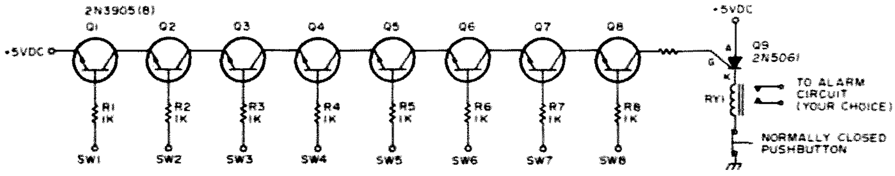

Fig. 3. Transistor-SCR alarm latch. Q1-Q8: 2N3905 PNP silicon transistors. Q9: 2N5061 sensitive gate SCR. RY1: 6 V dc, 335 Ohm coil relay (Potter and Brumfield RS5D); any sensitive 6 V dc relay will suffice. R1-R8: 1000 Ohm, ¼ Watt carbon resistors.

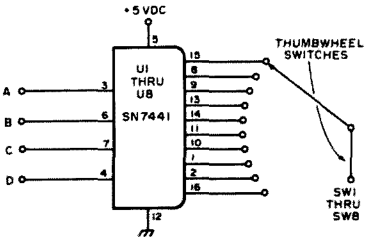

Fig. 4. 7441 drivers. U1-U8: SN7441 BCD to decimal decoders.

decoder, it now is used to "drive" the 0-9 pins of the decimal thumbwheel switch. As numbers are decoded by the 7441, a ground appears at the appropriate thumbwheel switch position. If the thumbwheel is set at this particular position, the ground will appear at the common or output of the thumbwheel.

The additional 7441s will also require plus 5 V dc for operation. This usually can be extracted from your present TTL 5 volt supply in the counter. If not, Fig. 2 illustrates a simple 5 V dc regulated supply.

Now that each of the digits in your counter chain has been sampled and is driving a thumbwheel switch, the alarm activation system comes into play. If all of the thumbwheel switches are set to a desired frequency and the counter displays this frequency, all of the thumbwheel switches will reflect a ground condition. By feeding the "common" of the thumbwheel switch to the base of a PNP switching transistor, a ground condition will cause the transistor to conduct. All of the transistors are placed in series so that when all of the thumbwheel switches reflect ground, all of the transistors will conduct, then completing the alarm circuit.

Our particular alarm circuit uses an SCR which has the ability to lock up or latch with a dc circuit (Fig. 3). The SCR will remain latched until the reset button (normally closed) is depressed, resetting the SCR. If the latch type of system is not desired, an ordinary reed type relay can be activated by the switching transistors. In this system, the alarm would sound when the counter frequency was achieved and then cease as a different frequency appeared.

Fig. 5 illustrates the pin numbers for the A, B, C and D outputs of a 7490 counter. If your particular counter does not have a 7475 quad latch (memory), these are the points at which the 7441 decoders would be attached for each digit of your counter.

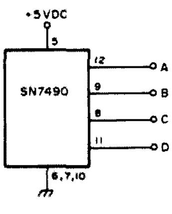

Fig. 5. 7490 wiring.

Fig. 6 illustrates the common SN7475 quad latch. If yours is of the more expensive type, the SN7475 quad latches will be employed. The SN7475 eliminates "flicker" or counting when the SN7490 counts up to its next set of figures. The SN7490 drives pins 2, 3, 6 and 7 (A, B, C and D respectively) and the outputs of the SN7475 are pins 16, 15, 10 and 9 (A, B, C and D respectively).

Once you have attached the SN7441 decoder to your particular counter, operation of this device is quite simple. All that is necessary is to dial up the desired frequency on the thumbwheel switches. When the counter arrives at this "dialed up" frequency, all of the PNP transistors (Fig. 3) will conduct also, causing the gate of the 2N5061 SCR to activate. The circuit from the anode to cathode of the SCR will also conduct, causing RT1 to close its contacts. Once an SCR "fires" it remains in this condition until the anode/cathode circuit is broken with direct current conditions. The normally closed push-button switch enables you to break the anode/cathode circuit of the SCR and "reset" the device.

Should the "latching" effect of the SCR be undesirable, an ordinary medium power NPN transistor can take the place of the 2N5061 SCR. Attach the base of the NPN transistor to the gate, the emitter to the cathode and the collector to the anode connections of the SCR placement. With this arrangement, the relay would only close momentarily as the desired frequency was detected. There would be no "latching" effect.

You will find that this device can be used with just about any binary counting device you may have built. Some common applications would be: (1) An amateur band edge detector; (2) A temperature alarm (with a binary digital themometer); (3) A pre-settable frequency detector; (4) An alarm for digital clocks; (5) A frequency counter for the blind; and, (6) A frequency limit detector for FM repeater transmitters. No doubt you will come up with many more applications for this device as digital electronics progress with amateur applications. ■

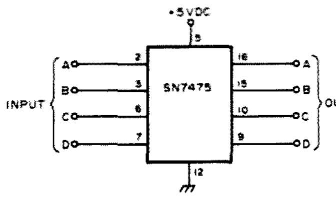

Fig. 6. SN7475 wiring. Note: There are four bistable latches in the 7475 package. The BCD binary code may be applied to any of the four latches desired. The BCD data to the 7441 decoders must correspond, however. In other words, there are no defined BCD inputs or outputs — they are up to you.

Programmable CW ID Unit

--for RTTY, repeaters, mobile, etc.

There have been many articles published on the subject of automatic identifiers. One might wonder what new could be said on the subject. Read on, and discover a circuit with the following features:

1. Uses almost no power.
2. May be used for both CW and RTTY.
3. Can be reprogrammed in less then one minute.
4. Self-contained. Only requires power and start signal.
5. Uses only 4 standard D.I.L. ICs, and one optional 8 pin minidip.
6. Runs on a single unregulated voltage source.

This whole unit is made possible by the CMOS logic family. This circuit is built around the Motorola MC14562CP, a 128 bit shift register. To make things simple, its operation can be described by saying, "what goes into the input will come out of the output 128 clock pulses later." What goes in is a "1" (high level) or a "0" (low level). When an output device such as an audio oscillator is connected, and a stored code (series of 1s and 0s) is recirculated by connecting the shift register output back into the input, this will cause the oscillator to be keyed as the data are shifted by. This code may be a simple repeater ID, or maybe a teletype test pattern. The only difference is the type of code, and the speed at which is is stepped.

Clocking

The clock signal is generated by one half of IC4. If the enabling control signals allow, the clock oscillator will free run at a rate determined by the values of R2 and C1 (refer to Fig. 1). I have found .47 uF to be a good value for the needed range, which is obtained by varying the value of R2. R2 may be a fixed resistor if a variable speed is not required. This clock signal passes through a gate which ORs with the manual step circuit. The manual step circuit is used to step through the program slowly, to examine, modify, or reprogram the contents. The manual step circuit consists of one half of IC1 crosswired with IC4, as a switch debouncer. With this circuit, each time the step pushbutton is pushed the shift register will step only once.

Control

Since the shift register has no way to know a starting or stopping point, we must add this external control. This is done by adding IC3, a seven stage counter, and IC1, wired as a flip flop. Every time the flip flop is set by a positive pulse, or the start pushbutton, the flip flop has its output set high, enabling the clock oscillator to run. With the clock running, the shift register starts stepping and the counter (IC3) counts the steps. When the final stage of the counter toggles on the 128th clock pulse, the transition causes the control flip flop to toggle back to the waiting state, stopping the clock. Since the output side of the flip flop is high any time the unit is running, this term is brought out through Q1, and Q2, to provide an external key for a transmit relay (or other logic). If only logic or some other low current load is to be keyed, Q2 may be omitted, and the emitter of Q1 grounded.

Audio Oscillator

The audio oscillator is identical to the clock oscillator, except, of course, for the frequency of oscillation. When the input pin 1 of IC4 is high, the oscillator will run, producing a tone. This tone from pin 4 of IC4 may be connected directly to a high impedance circuit, such as a microphone input, or a buffer amplifier consisting of IC5, a

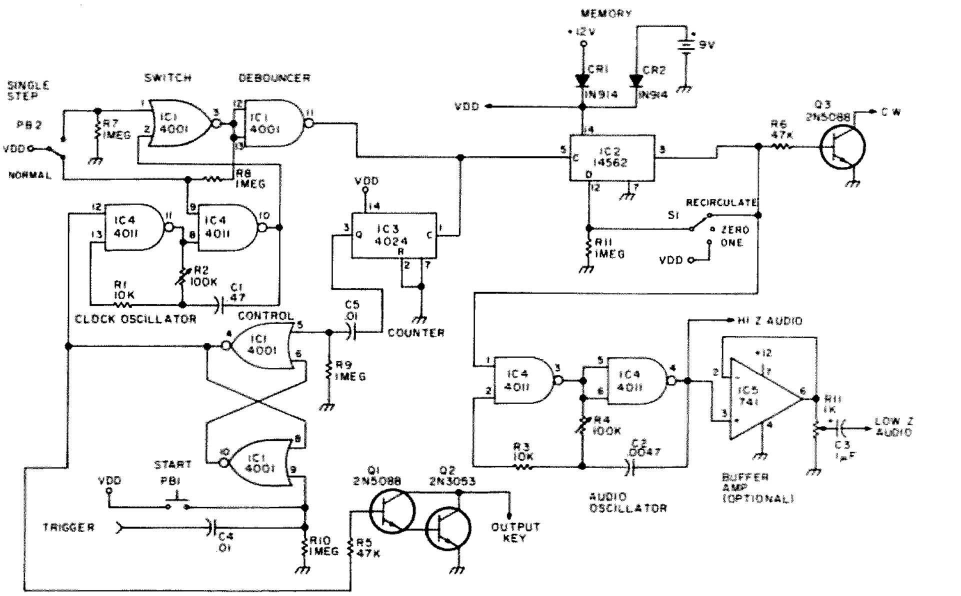

Fig. 1. VDD to power, pin 14; ground pin 7, all ICs. Standby current = 0 mA. Running current ≈ 1 mA (without buffer amp).

741 op amp. If the op amp is used, a low impedance audio line may be driven, or even a small speaker, without affecting oscillator pitch, or loading.

CW Output

If the direct CW output is desired, as would be needed in RTTY, the audio oscillator and buffer amplifier may be omitted and the output taken from the collector of Q3. A high level on the input of Q3 will turn it on, allowing the collector circuit to sink current. If the collector current to be keyed is to be more than a few milliamps, another transistor should be added in the same manner as was Q2.

Battery

It should be noted that a battery is connected to VDD through a 1N914 diode. The only purpose of this battery is to protect the contents of the shift register against loss of power. No power is drained from this battery since CMOS only draws power when it is running, and the circuit does not run without power. With power on and battery installed, the unit may be programmed and forgotten. Power may be turned off, and the unit transported, stored, or anything else, without fear of losing the program — and the battery will last for its shelf life. The entire unit may be run from a single 9 volt transistor radio battery, and, since only a few milliamps are required, the battery will last a very long time.

Programming

The best way to program the shift register is to "erase" memory by placing S1 in the program position, selecting the "0" position, and depressing the start pushbutton. This will dump the contents of the shift register into the proverbial bit bucket, leaving only zeros. Utilizing the program switch, select the desired "1" or "0" to be entered and depress the step push-button once for each step. When the entire program code has been stepped in, place switch S1 back into the recirculate position, and depress the start button, allowing the unit to cycle back to the start point. If an error has been made, it is not necessary to completely reprogram. Manually advance until error is reached, put S1 into the desired program position, step correction into the shift register, and return S1 to normal.

Many thanks to WA6CFA, who offered several constructive suggestions in the design of this circuit, and who is responsible for my switch to CMOS. ■

Parts List

IC1 — CD4001a quad 2 input NOR gate
IC2 — MC14562CP 128 bit shift register
IC3 — CD4024A 7 stage binary counter
IC4 — CD4011a quad 2 input NAND gate
IC5 — 741 type op amp (optional)
Q1, Q3 — 2N5088 NPN transistor
Q2 — 2N3053 NPN transistor
CR1, CR2 — 1N914 diode
R1, R3 — 10k ¼ Watt resistor
R2, R4 — 100k variable resistor
R5, R6 — 47k ¼ Watt resistor
R7-R11 — 1 meg ¼ Watt resistor
R11 — 1k variable resistor (optional)
C1 — .47 uF cap.
C2 — .0047 uF cap.
C3 — 1 uF cap.
C4, C5 — .01 uF cap.
S1 — Single pole double throw, center OFF toggle
PB2 — Single pole double throw, momentary contact push-button
PB1 — Single pole, momentary contact push-button
PCB — Printed circuit board, available from author ($3.50)

New ICs for the Counter Culture

-- simpler counters with less used power

The continued evolution of the integrated circuit industry has led to some developments which are of interest to the average electronics experimenter. Over the past few years the 7490-7475-7447 counter-latch-decoder/driver combination has been the mainstay for the construction of readout modules using either LEDs or filament type seven segment readouts. Likewise, the 7490-7475-74141 combination has been the basis for readout modules using Nixie tube readouts. The cost of these ICs has continually declined resulting in a relatively inexpensive digital display. The major drawbacks for building such a module are the PC board layout for the three ICs and the rather high current requirements. The PC board layout is no big obstacle since many have been published in electronics magazines, but the high current requirement remains. As an example, suppose you want to build a frequency counter with a six digit display and using the simplest possible circuitry. For purposes of illustration, miniature seven segment incandescent readouts drawing 8 mA per segment will be used. In the worst case condition (all 8s on the display), the readouts will draw approximately 335 mA. The counter-latch-decoder combinations will draw approximately 750 mA. Total current requirements will then be 335 + 750 mA = 1.08 Amps. This is a pretty healthy load and would be operating a regulator such as the LM309K beyond its maximum limits. Thus anything that can be done to reduce this power requirement would be advantageous.

Once again the IC industry has come to our rescue. In their TTL *Data Book For Design Engineers*, Texas Instruments lists several ICs which are directly applicable to a construction project such as a frequency counter. The first IC to be discussed is the 74144. This device comes in a 24 pin DIP package and combines the features of the 7490-7475-7447 into one IC. All internal connections available from the three IC module are available from the 74144. For example, BCD outputs from the latch, RBO, RBI, latch strobe, carry output and look-ahead counting connections are all externally available. Other desirable features are relatively low current drain (65 mA) and simplified PC board layout. The one possible disadvantage is in the counting speed (typically 18 MHz), which may be a factor if high speed operation is needed. The seven segment outputs are "active low" and can handle 25 mA, thus making the 74144 suitable for driving incandescent readouts such as Numitrons (from RCA) and other filament type readouts in addition to LEDs. Using six 74144s in our counter would reduce the 5 volt current requirements from 1.08 Amps to 725 mA, which is well within the capability of the LM 309K regulator. A

companion to the 74144 is the 74143. This IC has all the features of the 74144 plus current limiting outputs which are set at 15 mA. The 74143 is specifically designed for driving LED type displays. A base diagram for the 74144 and 74143 is shown in Fig. 1.

If your interest lies primarily with the use of Nixie tubes rather than incandescents or LEDs, TI has come to your rescue also. The 74142 contains the counter, latch and decoder/driver for cold cathode Nixie tubes and comes in a 16 pin DIP package. Only the necessary internal connections are brought out to pin connections, thus allowing use of the 16 rather than the 24 pin package. The base diagram is shown in Fig. 2. Again some savings in power consumption can be gained – typical current requirements for the 74142 are 68 mA versus 77 mA for the three IC combination. Maximum counting frequency for the 74142 is typically 20 MHz. This IC is also particularly attractive for frequency scanner applications.

Another IC which may be of interest to the experimenter is the 74147. This 10 line to 4 line encoder provides the capability of decimal to BCD decoding. In the past, if you needed a BCD code for some decimal number, either a diode matrix or a BCD switch was necessary. Both are relatively expensive and the diode matrix consumed a large amount of PC board space. Now, by using an ordinary single pole ten position switch and the 74147 IC, the BCD code can be derived directly from the equivalent decimal number. Fig. 3 contains the base diagram.

Most of the ideas presented herein were gleaned from the *TTL Data Book For Design Engineers* (CC-411) by Texas Instruments, and it is well worth the price. ■

Front view of "ERF" meters. Left: tuned input. Right: untuned input.

Edwin Hartz K8VIR
PO Box 127
Holly MI 48442

Is My Rig Working or Not?

--build an effective radiated field meter and know!

How many times during a pileup or an unanswered CQ have you wondered, *am I really getting out?* Sure, you can check modulation, transmitter voltages and currents. And if you have a standing wave ratio meter, you can also check antenna match "swr."

But what about that rf field? After all, that's what counts! When you measure your rf field, you are in fact measuring total performance of your system. You may at first think such an instrument would be both expensive and complicated. It would be if you were interested in precise measurements. But we need only relative field measurements; therefore, adequate instrumentation can be both simple and inexpensive.

The circuits discussed are of two basic types: an untuned input and a tuned input. The untuned input provided no selectivity while the tuned input will measure the field and approximate frequency.

Construction

The construction of the meters is very basic and quite flexible. As you design rf meters for higher frequencies such as the VHF bands, you should place components so that lead lengths in the rf circuitry are as short as possible. The enclosures I used were Universal Meter Cases but most any type chassis or small cabinet will be adequate. The enclosure ought to be metal as the

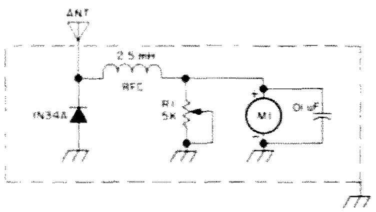

Fig. 1. Untuned circuit. M1 — Dc meter (see text). R1 — Sensitivity control.

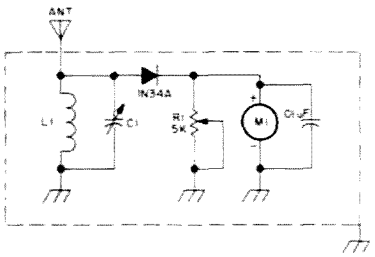

Fig. 2. Tuned circuit. M1 — Dc meter (see text). L1 and C1 — Resonant combination to cover frequencies you desire.

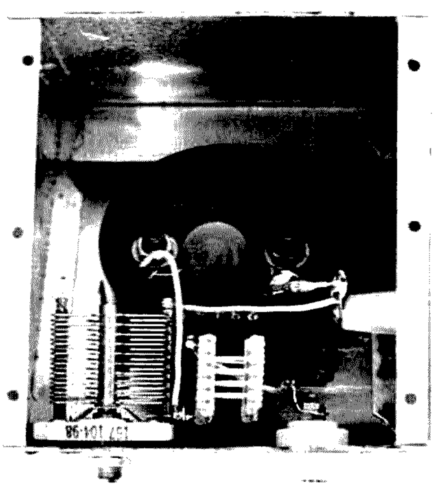
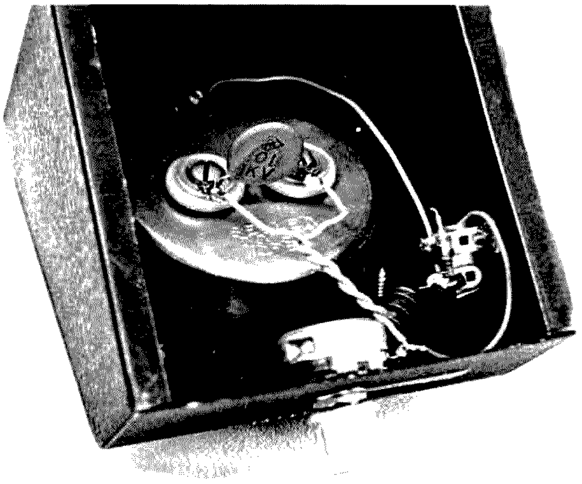


Internal view of tuned input meter.



Closeup internal view of untuned meter.

circuitry should be shielded. To shield the Universal Meter Case, I used some roof valley aluminum to enclose the rear opening. It can be easily cut to size with hand scissors. You will find this available at most lumber yards or hardware stores.

Instrument Sensitivity

Sensitivity of the instrument is determined by the full scale deflection of the meter chosen. The smaller the full scale deflection, the greater the sensitivity; for example, a 0-50 uA meter will be more sensitive than a 0-1 mA meter. I used a 0-1 mA meter for the untuned meter and a 0-200 uA meter for the tuned meter.

The length of your reference antenna will also affect sensitivity: the longer the antenna, the greater the sensitivity. Also, dc resistance of the rfc will affect sensitivity. Choose an rfc with low dc resistance for maximum sensitivity.

Instrument Application

Once you have your field strength meter constructed and operating, you can begin making some reference measurements for future use.

What I do is install a small reference antenna outside the immediate area of the transmitter; it does not have to be a great distance from it. The important item is not to change the location or length of the reference antenna once you start basic measurements.

For measurements with a beam, I note and record on paper degrees of rotation "direction" and power input into antenna transmission line. With a dipole or fixed array, direction need not be recorded, but you must record input. Next, I proceed to measure field strength with the meter. I record in my log the relative reading for future reference, and if I suspect a problem antenna or otherwise, I immediately go back to my original readings and make a measurement. If you have significant energy loss in your ERF, it will show.

You will also find the "ERF" meter a valuable instrument for mobile or portable operation. ■

Quickie Collinears for 15 and 10

- - satisfaction guaranteed

John Skubick K8ANG
1040 Meadowbrook
Warren OH 44484

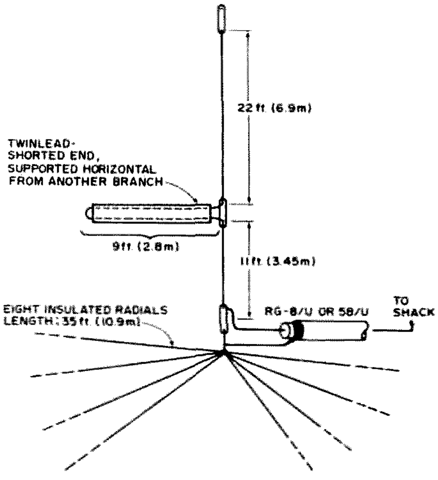

Fig. 1. 15m collinear.

I had just moved into another house. I needed two more continents for WAC, it was sleeting outside, and no antennas! This could only happen to a ham. I had to think of something!

The idea was to pack as much gain as possible into a simple antenna that I could quickly build with available leftover materials. The *ARRL Antenna Book* provided the initial data. I chose 15 meters, because my rig has only 80 Watts output. There were too many high powered boys on 20, and 10 meters was too sporadic. See Fig. 1.

Construction

The two vertical sections and the eight radials were made from carefully measured, 18 gauge, insulated, solid hookup wire. The quarter wave stub was cut (using the 0.82 velocity factor) from a piece of TV twinlead. Some old ribbed ceramic insulators I had were used at the base, stub and top.

The whole works was put together in my basement, in about one and a half hours. Then I coiled up everything, coax and all, and went out into the mid-November sleet.

Installation

One of my backyard maple trees was used as a "mast." I tied fishing line around the head of a small hammer, and proceeded to toss this up and over an estimated forty foot high branch. After about a hundred or so attempts, the line was over the branch and tied to the antenna's top insulator. This was then hoisted up until the antenna's bottom insulator (with coax and radials attached) was clear of the ground by about one foot. The bottom insulator was held in place with another piece of fishing line tied to a short stake pounded into the ground just below it. I then spread the insulated radials out along the ground, and placed rocks at their ends to keep them taut.

The RG-58 feed line was also left on top of the ground. I brought it into the basement through a small hole drilled into the metal window frame. Then I soldered a coax connector to the end.

Results

I warmed up the rig, attached it (along with the coax) to my swr bridge, and then switched it to "tune." *Horrors* – 4:1 swr! I looked outside. It was getting dark and still sleeting. I removed the swr bridge.

For the next three hours, I was working VKs, ZLs and JAs – for the first time. Just what I needed for my last two WAC continents! I left the antenna "as is" all winter.

Twinlead	Open wire
6.7 ft	7.7 ft
20 ft	23.2 ft
33.4 ft	38.7 ft
48.8 ft	54.2 ft
60.2 ft	69.7 ft
73.5 ft	85.2 ft
86.9 ft	100.7 ft
100.3 ft	116.2 ft

Table 1. Odd multiple lengths of balanced transmission line, using velocity factors of 0.82 for solid dielectric types, and 0.95 for open wire types. All lengths are subject to trimming for low swr.

I wanted to get on ten meters as quickly and as *cheaply* as possible with a gain antenna, using available materials in my junk box. After looking through my references, I reasoned that a wire-type two element collinear might just do the job. I was looking for performance at the low radiation angles. Also, I did not want to pump any rf directly into the ground from the transmission line. In other words, I wanted *no* messy, lossy (for practical amateur installations) radial system with this vertical.

Fig. 2 shows what my junk box yielded, as well as the dimensions. I used 450 Ohm TV open wire for the elements, to help broadband the system. I also decided to bring the balanced feeder all the way into the shack, because I was not about to do any outside tuning and pruning in the middle of winter. My twinlead feeder was the UHF oval-foam type. The important thing here is to use something with low loss. Open wire feed will have to be used for high power. You can use the TV or home brew variety of open wire lines.

My balun is a 4:1 toroid type. Possibly a 1:1 balun can also be used, because the feed line has to be trimmed for minimum swr anyway. If you have a tuner, no balun is needed, of course. The balanced feeder may still require a little trimming, if you are experiencing difficult loading, for 1:1 swr.

Construction and Installation

The elements were laid out on the basement floor, measured, and cut. I attached three ceramic insulators (top, middle and bottom), along with the twinlead feed line. All of this was then coiled up and taken outside. I selected one of my backyard maple trees and sighted on an estimated 35 to 40 foot branch. After the usual countless attempts at tossing a weighted fishline, I finally got it over the branch. A heavier cord was tied to this and to the top of the collinear, and then hauled up until the antenna's bottom insulator cleared the ground by about one foot. I tied the bottom insulator to a stake that was sledgehammered into the frozen ground directly below.

A "strain guy" made of fishing line was tied around the center insulator. This was to counteract the opposite pull of the (sort of) horizontally supported feed line. Some branches from another tree supported the feed line (more fishing line). At the house, the feeder was attached to TV standoff insulators (about every six feet) down to the basement window. I drilled and filed out an oversized hole in the window's metal frame, and inserted a large grommet. Purists take note. I then pushed the balanced twinlead feed line through this grommeted metal-surrounded hole.

(See Table 1, and make sure you have several feet of extra twinlead for trimming purposes.)

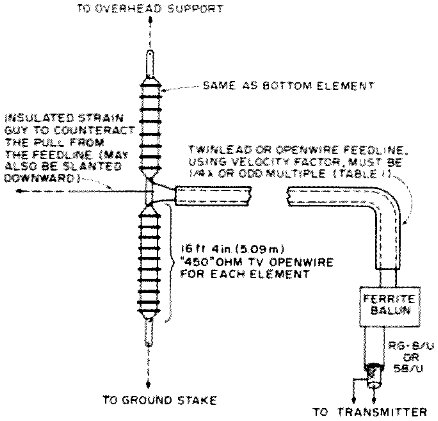

Fig. 2. Vertical collinear for ten.

The Tuneup

The rig was fired up into the swr bridge, with the balun and feed line attached. Reduced power was used at first, and a frequency sweep was made across the entire ten meter band. Well, how about that! The lowest swr (8:1 for my installation) occurred at 28.6 MHz! At that point of lowest swr, I then trimmed the twinlead for 1:1. Another frequency sweep was made. The swr was 1.8:1 at 28.005 and 2:1 at 29.65 MHz. The broadbanded construction paid off!

Results

The sporadic nature of ten meters made it difficult to evaluate. However, I was easily able to work the DX (when it was there) with my 260 Watts PEP transceiver. Needless to say, I was satisfied! ■

500 MHz Scaler

-- PC boards are available

Although integrated circuits for a 500 MHz frequency scaler have been available for a number of years, their price of $50 and up has been a stumbling block to the average ham. Recently, however, Fairchild introduced their 11C90 UHF decade counter which, at only $16 in single quantities, represents a real breakthrough for those needing a way of counting frequencies to 450 MHz and above. Although operation of this IC is only guaranteed to 550 MHz, the typical 11C90 will reach 650 MHz and beyond.

This article presents a simple and low cost prescaler using this IC which may be built for as low as $20. To ensure simplicity and low cost, an input amplifier is omitted and thus the scaler is a bit finicky as to the amount of rf it needs. In practice, it will accurately monitor the frequency of a 2 meter or 450 MHz 1 Watt walkie-talkie from a distance of about 3 feet away. Higher power transmitters can be located farther away.

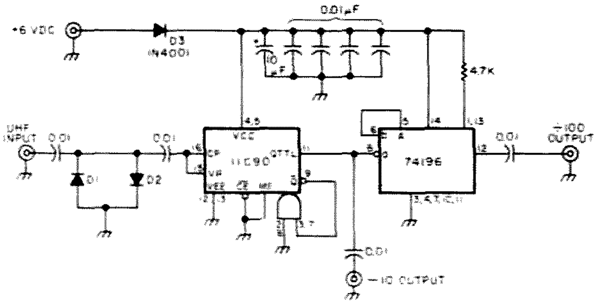

Fig. 1. 500 MHz scaler diagram.

Since the 11C90 divides by ten, the output will be in the range of about 45 MHz with an input frequency of 450 MHz. This is perfectly acceptable if you already have a counter or scaler which will cover that range. For example, the K2OAW VHF Scaler (see *73 Magazine* for June 1973) or the K2OAW VHF counter (*73 Magazine*, November 1974) make an ideal companion for this new scaler. But if your counter does not have a high enough frequency range, then this scaler design has room for an optional 74196 TTL decade counter which provides an additional division by ten. A 450 MHz input frequency will then be converted to 4.5 MHz.

Fig. 1 shows the circuit of the scaler. An input to be scaled is coupled to the CP input of the 11C90 through a simple protective circuit consisting of diodes D1 and D2. Fast switching diodes such as 1N914 or 1N4148 should be used. Actually, these two diodes don't furnish much protection at UHF; to work at UHF, special high speed diodes would have to be used. Such diodes are not only hard to get, but are also very fragile. When driven from a short antenna with a source resistance of 50-70 Ohms, they would probably burn out even before the 11C90 was in danger. Instead, we put in D1 and D2 mainly to guard against inadvertent low frequency overload, and rely on a little care on your part to avoid overload. The specified input sensitivity of the 11C90 is approximately 200 mV rms, and the maximum signal should be less than 1 volt at frequencies below 450 MHz, decreasing to less than 500 mV at 600 MHz.

The 11C90 has a built-in level converter which provides a TTL-compatible output at pin 11. If your counter covers a high enough frequency, this output can be used as is. If needed, you may add the 74196 as a second decade counter as shown.

A compact arrangement with short leads and a solid ground is needed. It is recommended that a printed circuit layout (such as Figs. 2 and 3) is used. (Etched and drilled boards are available for $7 each from Star-Kits, G.P.O. Box 545, Staten Island, N.Y. 10314.)

The entire scaler requires

less than 150 mA from a 5 volt power supply. Though a simple supply could be built, in practice a battery supply is an easier and better choice. Four D cells or a lantern battery will provide 6 volts dc, which will drop to about 5.25 volts after the 1N4001 diode. If you use four nicads, the diode is not needed as the nicads will supply 5 volts directly. But a good stiff supply is needed – penlight cells won't do.

Both ICs are very sensitive to extraneous signals on the power and ground lines. If you look at the diagram and at the circuit board layout, you will see four 0.01 uF capacitors bypassing the 5 volt line to ground. (One of these capacitors is not shown on the circuit board layout as it is soldered directly from pin 4 to pin 13 on the copper side of the board, under the 11C90.) Disc ceramics with very short leads should be used.

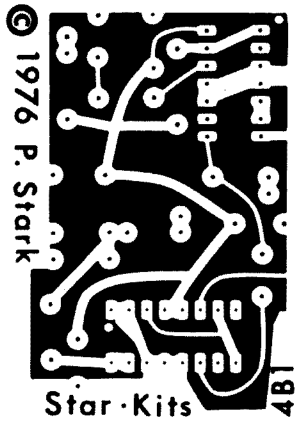

Fig. 2. PC board, foil side (full size).

The entire scaler should be enclosed in a metal cabinet with coax cable used for coupling to the counter. Batteries or power supply should also be in the cabinet to avoid stray rf on the power leads. If desired, the scaler can be mounted inside the counter cabinet.

Except for these simple precautions, this scaler is easy to build. My thanks go to Fairchild for the excellent – and cheap – scaler IC. At $20 for all the parts, this scaler circuit is an excellent value. ■

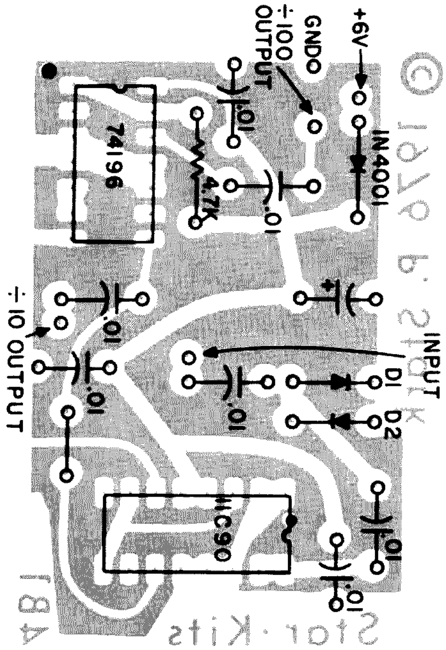

Fig. 3. Component layout.

Build a Super Standard

- - goes right down to 1 Hz

Terry Shankland WA7VVC
1909 E. El Parque Dr.
Tempe AZ 85282

With the proliferation of subbands and interference-obscured net frequencies, the use of an accurate secondary frequency standard is both good operating procedure and also helps fill our legal requirements for frequency measurement capability under FCC regulations. In addition, such a standard can be used as a timebase or signal injector to test digital logic circuits.

The WA7VVC frequency standard was designed to be a low cost answer to the need for a good secondary frequency standard. It generates marker signals of 1000, 500, 100, 50, 25, 10, 5, and 1 kHz, and 100, 10, and 1 Hz. With harmonics usable well beyond 30 MHz, markers are available to denote subband edges, align receiver dials, find net frequencies, and measure the frequency of unknown signals. Should your latest logic circuit not perk properly, two TTL level outputs are available as substitute clocks or signal injectors.

Short term accuracy is approximately 1 part in 10^6. The unit is easily aligned to WWV with a short wave receiver. An attenuator is included to permit matching signal strengths with the received signal so that a zero beat can be easily and accur-

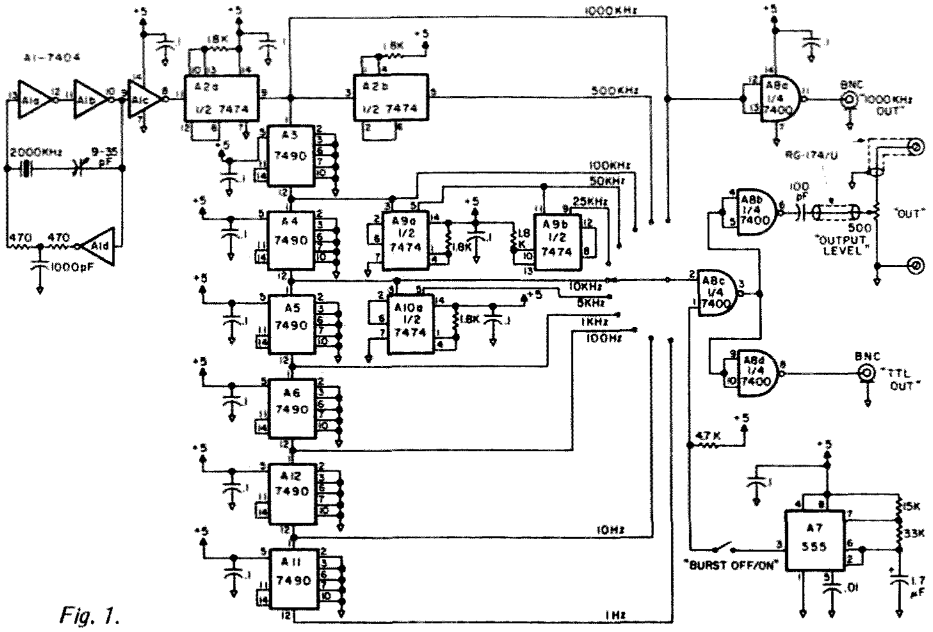

Fig. 1.

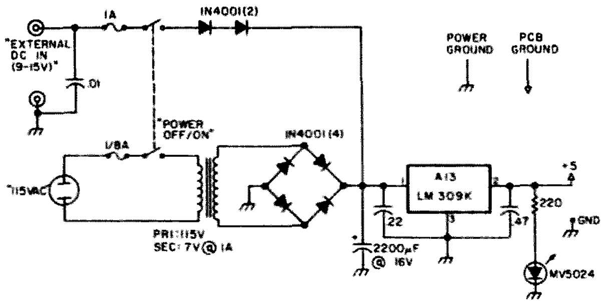

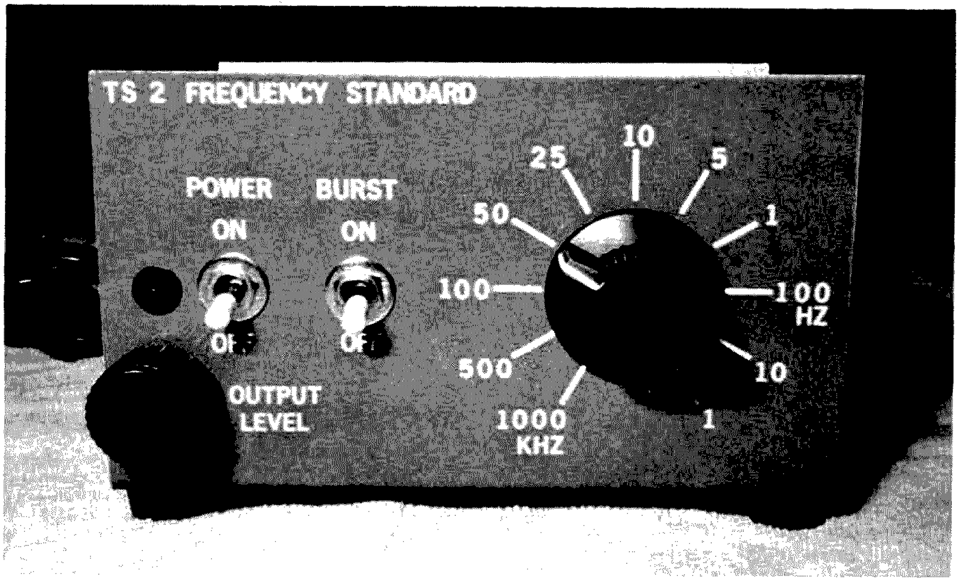

ately identified. Only one trimmer need be adjusted to align the standard.

With the standard still attached to the receiver and providing an audible measure of its accuracy, a counter or other TTL-compatible device may be attached to either TTL output and that device's accuracy checked.

A frequency burst mode is provided to allow identification of the standard's markers in a crowded receiver passband. Enabling the burst turns the output on and off ten times per second, resulting in an easily recognized "beep-beep-beep." This burst is also available on one TTL output.

An external dc input makes operation in the field possible. 9-15 volts at 250 milliamps is all that you will need to have an accurate standard available for Field Day. This is cheap insurance against FCC out-of-band citations.

Circuit Description

The active devices in the frequency generation chain are 7400 series TTL. They are readily available, easy to use, inexpensive, and capable of the fast rise times necessary for high level high frequency harmonics.

The oscillator shown in the schematic of Fig. 1 uses a 7404 hex inverter, A1, with a 200 kHz crystal as the feedback element for frequency stability. This circuit provided the cleanest output of those I tried. I happened to have a 2000 kHz crystal on hand but the circuit will work with a surplus 1000 kHz crystal. In fact, you can eliminate one 7474 package by using a 1000 kHz oscillator.

Frequency division is accomplished by 7474 dual type D flip flops A2, A9, and A10, and 7490 decade counters A3-A6, A11, and A12 wired for division by ten. The 7474s are used as toggle flip flops by connecting $\bar{Q}$ to the data input. Preset and clear are not used and are tied high through 1.8k resistors. The 7490s are ripple counters and are prone to spikes and level changes in their output. Proper bypassing of all ICs is necessary to prevent these devices from putting spikes on the power buses. The .1 uF bypass capacitors are not superfluous – use one at each IC.

The various frequency outputs are selected by a rotary switch and fed to A8c, one section of a 7400 quad gate. The selected frequency can either be passed without change or gated with the 10 Hz output of A7, an NE555 astable oscillator, producing an easily identified frequency burst at the output terminals.

Should you not have a switch with enough positions to suit your needs or just wish something different in the way of frequency selection, try the electronic switch of Fig. 2.

The NE555 timer A14 is used as an astable oscillator whose output is a train of 24 millisecond low-going pulses with a period of .81 seconds. A15a inverts this to a train of positive-going pulses. A15b and A16a gate the pulse train under control of the STEP push-button switch.

On each low-going pulse edge at pin 14, the 7493 binary counter A17 increments by one. A16b forces a reset on a counter output of 1011, permitting outputs from 0000 through 1010 to select the eleven frequencies

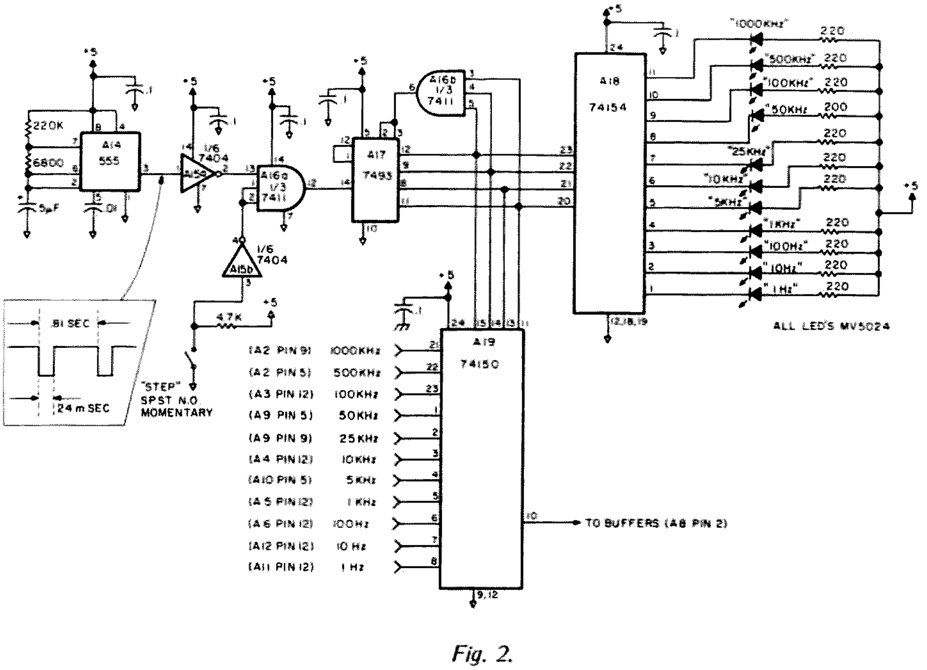

Fig. 2.

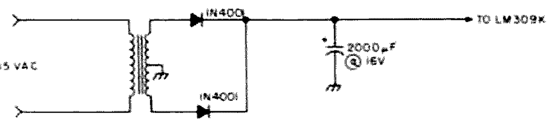

Fig. 3.

of the standard.

The binary output of A17 causes the 74150 multiplexer A19 to select a signal from its inputs to be fed to the standard's output buffers. A18, a 74154 binary to one of sixteen decoder, enables the corresponding LED.

To change frequencies on the standard, depress the STEP push-button. The standard will step through its eleven outputs, one every .8 seconds, until the button is released. When the desired frequency is reached, as indicated by its LED, you have three-quarters of a second in which to release the button before the standard steps again.

Because of the additional current required by the electronic switch, the 2200 uF filter capacitor should be changed to 4700 uF if this circuit is added.

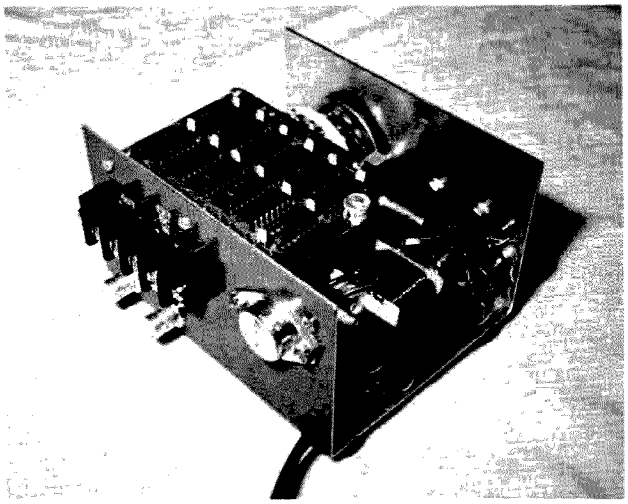
The remaining gates of the 7400 are used as output buffers. The two used for TTL outputs will drive ten TTL loads apiece. One of these gates buffers the 1000 kHz output of A2a and makes it available at a BNC jack on the rear panel. The other takes the output of A8c, which is controlled by the frequency selector and the BURST switch, and makes it available at a BNC jack.

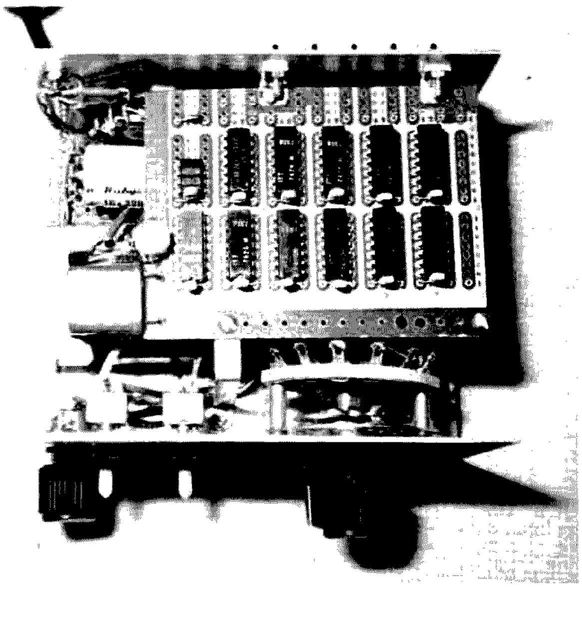
The output to a receiver is from A8b through a 100 pF capacitor and a 500 Ohm pot used as a signal level attenuator. Connection of the pot as shown on the schematic prevents the receiver sensitivity from being affected by the attenuator setting.

The power supply uses the ubiquitous LM309K +5 volt regulator. Since the circuit draws only 250 milliamperes, the project case can be used as the heat sink. Dissipation of the 309 is only 0.7 Watts.

Substitution for the surplus 7 volt power transformer I used is easy. Use a 12.6 volt center-tapped filament transformer in the configuration of Fig. 3.

In order to use the unit in





the field, provision is made for an external dc input. The .01 uF capacitor removes stray rf from the power lines and the series diodes prevent damage from polarity reversal. Two diodes were used because I feel that the 14.5 volts of a car battery under charge come perilously close to the filter capacitor's 16 volt rating. With the two diodes shown, applicable dc input voltage is 9-15 volts. With the appropriate filter capacitor voltage rating and a single diode, voltages in the range of 8 to 25 can be used.

Do not leave out the .22 uF bypass capacitor on the 309 input. It prevents oscillation of the device should a remote battery be used as a power source.

Construction

Because of the high speed switching characteristics of TTL and the high frequency harmonic content of the output waveforms, each IC is a transmitter and each interconnecting wire is an antenna. A thoughtful layout and careful construction are important to minimize unwanted radiation.

Switching transients appearing on the Vcc and ground lines can add unwanted noise to the output. I used a prototyping board with Vcc and ground planes to minimize glitches. A printed circuit board would be even better. If you wish to build the circuit with wire wrap sockets on vectorboard, use bus wire for the power leads to the sockets. An effective technique is to interleave Vcc and ground bus wires for each row of IC sockets, with a row not containing more than a half-dozen ICs.

Bus wire should also be used to connect the board directly to the 309. Do not invite problems by grounding the board to the chassis. Connect the chassis to the 309 case, the board to the 309 case, and the rectifier ground to the 309 case. This prevents the board ground from rising above the power ground and developing noise problems.

Asynchronous TTL devices such as the 7490 generate plenty of switching transients. Put a .1 uF bypass capacitor between Vcc and ground at each device socket and another at the power input to the board. Bypass the 309 input and output as shown in the schematic to prevent spikes and oscillation.

The leads connecting the frequency divider ICs and the selector switch make excellent antennas, so shield the output from the board to the attenuator pot and from the pot to the output terminals with RG-174 coax to reduce unwanted pickup. Long unshielded leads will reduce the effective control range of the pot.

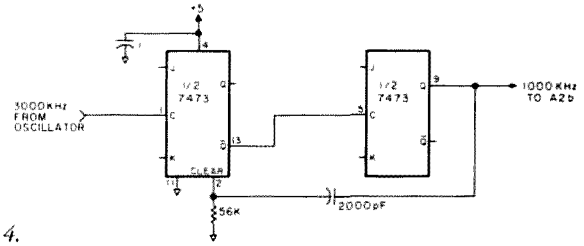


Fig. 4.

Mechanical stability will be reflected in electrical stability. Rigidly mount the crystal and trimmer capacitor close to the 7404 oscillator.

Changes

For those who would like accurate channel markers for 2 meter FM, try a 3000 kHz crystal in the oscillator. This frequency can be divided by two 7490s to 30 kHz for standard channels and then by half of a 7474 to cover splinter channels. The divide by three circuit of Fig. 4 replaces A2a to retain the outputs of the present standard.[1]

With CMOS prices falling and use of these devices increasing, you may wish to provide an output compatible with CMOS logic circuits. A 7406 open collector hex inverter package with a 2k pullup resistor could be added to interface with CMOS logic levels. Such an arrangement will have a deleterious effect on high frequency harmonic content, but will be fine for signal injection to a CMOS circuit. ■

The Incredible Lambda Diode

-- you can even make it yourself!

Do you remember the Tunnel Diode of days gone by? You may have seen it used in various oscillator and converter circuits and in other types of high frequency applications. The main reasons for using these devices were low power consumption, good frequency stability, and extremely simple circuitry. In addition to these features, it is also possible to use the Tunnel Diode as a voltage controlled oscillator well up into the VHF range. With all of these features and the availability of low cost devices, it would seem that Tunnel Diodes would find their way into a lot of circuits, right? Wrong. For one reason or another, the Tunnel Diode has not been used to a great extent in everyday electronic circuits. Perhaps they were not sophisticated enough for some designers or maybe the device was not suited for the application at hand. But for whatever the reasons may have been, we have turned to other devices, such as the FET, for oscillator circuits and other high frequency applications.

Just recently, a new circuit device has been developed that behaves like a Tunnel Diode, but has all of the advantages of field-effect transistors. The new device is called a Lambda Diode, for reasons which will become apparent later, and is the subject of this article.

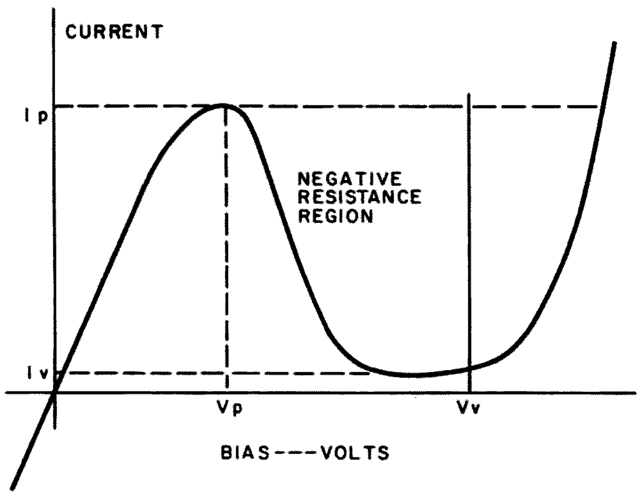

Fig. 1. Typical characteristics of a Tunnel Diode, showing the negative resistance region of the voltage vs. current curve.

Background

Before leaving the Tunnel Diode completely, perhaps a review of its characteristics will help in understanding how the Lambda Diode works and how to apply it properly.

The Tunnel Diode is a basic two terminal device that exhibits a negative resistance at certain voltages. What this means is that as the voltage across the device is increased, the current will also increase up to a point. When the voltage reaches this particular value, the current through the device will level off. Then any further increase in voltage will result in a proportional decrease in current through the device. This characteristic is illustrated in Fig. 1.

The negative resistance is the result of the diode having a small p-n junction with a high concentration of impurities in the p-type and n-type semiconductor materials. Having a high impurity density makes the junction depletion region narrow so that the electrical charges can transfer across the region at almost the speed of light. This effect is called "tunneling" and was first discovered in 1957 by Dr. Leo Esaki when he announced the results of his experiments dealing with highly doped p-n junctions. This was the first time a negative resistance device was produced, although the tunneling effect was predicted mathematically as early as 1929 by three physicists.

It is this tunneling effect in the negative resistance

region on the characteristic curve of the device that makes it possible to achieve amplication, pulse generation, and rf energy generation.

While the Tunnel Diode held great promise when it was first introduced, it seems to have been sidestepped in our race for better and more efficient devices. Perhaps it deserves a closer look by many of us who have forgotten how easy it is to use in designing electronic circuits. Coming to our aid in this regard is a new device that brings the negative resistance circuit element into a new realm of activity. The new device is called the Lambda Diode and it appears to have a very exciting future.

The Lambda Diode

Like its tunnel diode counterpart, the Lambda Diode is also a two terminal device, but it is constructed with a pair of complementary depletion-mode junction-field-effect transistors connected as shown in Fig. 2. According to manufacturers of the device, it is easier to fabricate than conventional devices and it can be produced on one chip along with other devices. However, unlike Tunnel Diodes, Lambda Diodes are not limited to a narrow resistance region and consequently can be produced with a wide range of characteristics.

Although these devices are too new to be available on the surplus market, it is possible to build your own Lambda Diode from a complementary pair of JFET transistors. Fig. 3 shows the general layout for the Lambda Diode constructed from an n-channel and a p-channel JFET available from Radio Shack and other suppliers.

The name for the device is derived from the shape of its voltage-current characteristic curve, as shown in Fig. 4. Like the Tunnel Diode, when a positive voltage is applied to the anode of the Lambda Diode, the current through the device increases until the applied voltage reaches the pinch-off voltage of one of the devices. At this point on the curve, the voltage is called the peak voltage, Vp, and the peak current is Ip. Increasing the voltage further will cause the current to decrease until the applied voltage is equal to the sum of the pinch-off voltages of both JFETs. At this point, the voltage is referred to as the valley voltage, Vv, and both of the JFETs are cut off. Current draw in this state is low (in the order of a few nanoamps) and this feature makes the device a good choice for low power consumption applications. This minimal current will be limited for further increases in voltage until breakdown of one of the gates occurs.

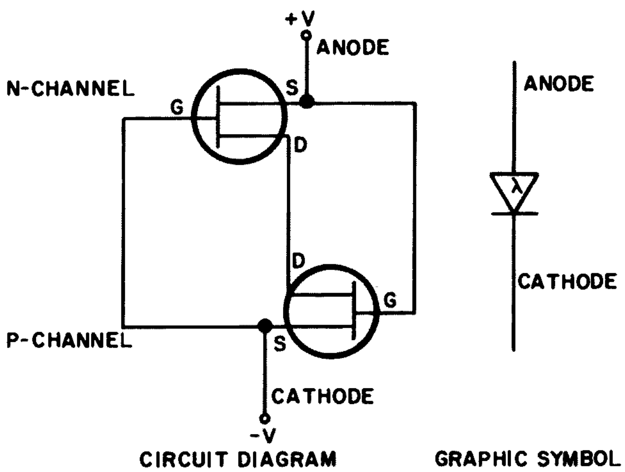

Fig. 2. The Lambda Diode is a two terminal device consisting of a pair of complementary depletion-mode junction-field-effect transistors connected as shown.

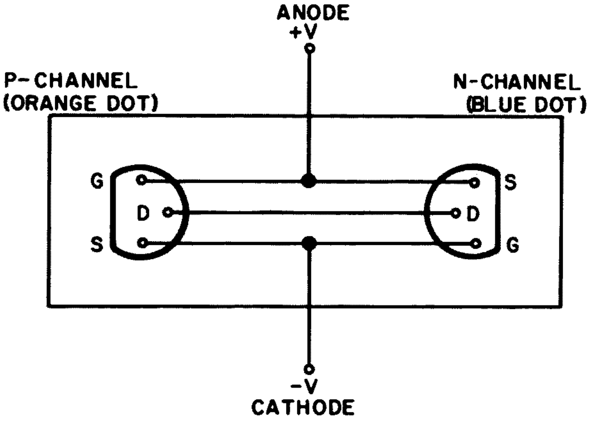

Fig. 3. This is a top view showing how two complementary transistors are connected to form a Lambda Diode. JFETs from Radio Shack (276-112) were used in this instance, although a 2N4360 or similar could be used for the p-channel and a 2N3819 or similar could be used for the n-channel.

The basic characteristics of this diode make it useful for many applications including oscillators, transistor protective circuits, battery monitors and many other circuits requiring low "off" states at high voltages.

Lambda Diode Applications

One useful application for the Lambda Diode is an electronic fuse that is non-destructive, fast acting and provides low current protection. Three such protective circuits are shown in Fig. 5. When an abnormally high voltage is applied to the power transistor, the diode will move into its negative resistance region, effectively cutting off bias to the transistor and allowing it to turn off and protect itself. For higher current applications, the diode can be connected in Darlington fashion as shown in Fig. 5(b). Similarly, for higher voltages, it can be connected as a sensing element to control a particular transistor as shown in Fig. 5(c).

Battery Voltage Monitor

Since the diode displays a bistable switching characteristic with almost zero standby current draw, it also makes a good battery voltage monitor. Simply connect the Lambda Diode as shown in Fig. 6, using a 2N2222 transistor and any LED as a low voltage indicator. Voltage measurements on the two JFETs I used resulted in the LED being switched on at 8.7 volts. This "switch on" voltage was found to be ideal for devices powered by a 9 volt transistor battery. However, you can change this transfer point by selecting JFETs with higher or lower pinch-off voltages than the ones I used.

In this particular circuit, as long as the battery stays in its normal operating range, the device will not draw any current due to its excellent "off" state characteristics. For this reason, the Lambda Diode makes an ideal battery voltage monitor.

Power Failure Monitor

Another application for the Lambda Diode is a power failure monitor as shown in Fig. 7. This particular circuit

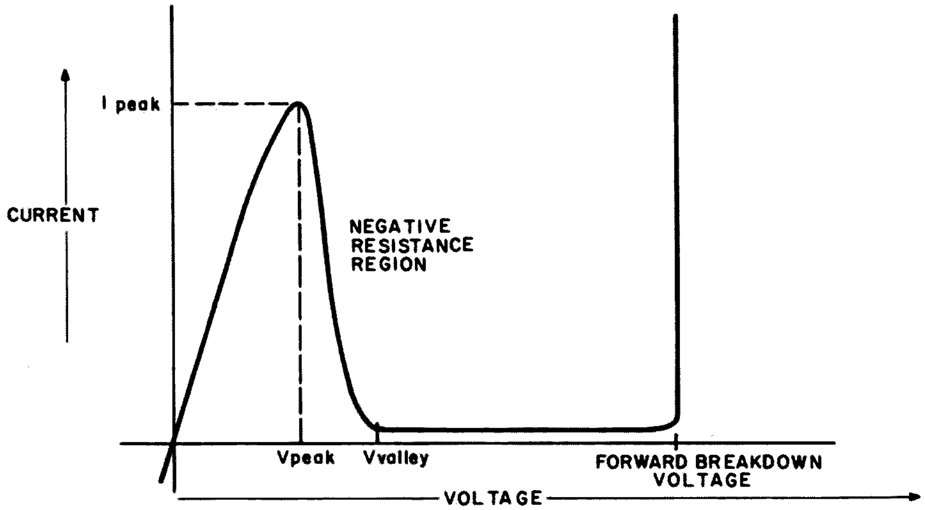

Fig. 4. Like the Tunnel Diode, the Lambda Diode displays a negative resistance characteristic when its bias voltage is increased past the peak shown on the graph.

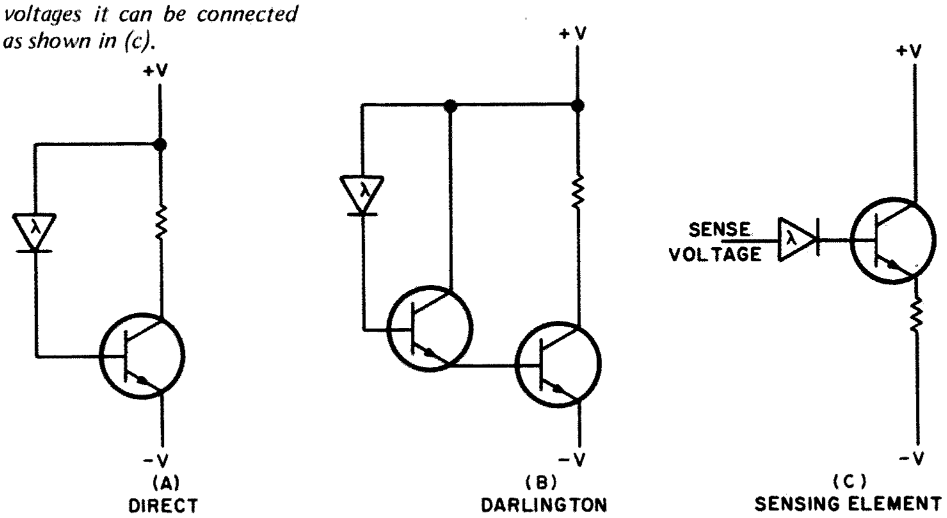

Fig. 5. The Lambda Diode makes an excellent electronic fuse when it is used to supply bias to the transistor it is protecting. An increase in current will cause the voltage drop across the collector resistor to increase, turning the Lambda Diode off. This will in turn cause the transistor to stop conducting. For higher current capabilities, it can be connected in Darlington fashion, and for higher voltages it can be connected as shown in (c).

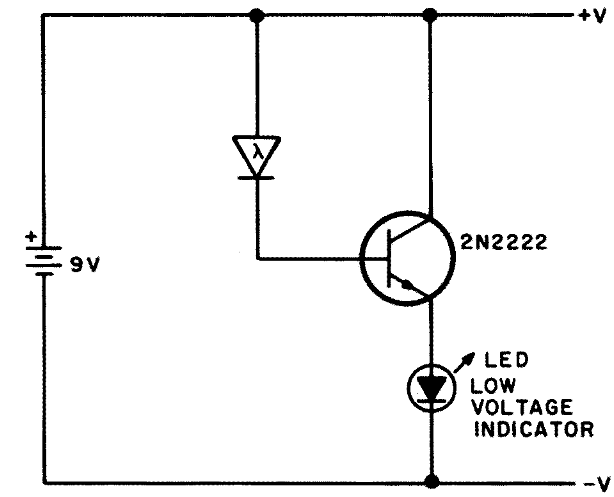

Fig. 6. Battery voltage monitor. With the Lambda Diode I was using, the LED would turn on at 8.7 volts, which makes it ideal for a 9 volt transistor battery. However, by using other JFETs with different pinch-off voltages, it may be possible to raise this transition voltage to monitor other power supplies.

will find application in products such as digital clocks, security systems, and computer operations. Basically, two transistor drivers are connected to LED indicators, with one transistor biased by the Lambda Diode. Under normal operating conditions, the diode is off, keeping transistor #1 turned off. Under these conditions, only transistor #2 is on, with the green LED indicating a "power on" condition. When a power failure occurs, of course, both LEDs will be off for the duration of the power failure. Then when power is restored, the Lambda Diode will be "on" causing the red LED to come on, indicating a power failure has occurred, and the green LED will be off. After the reset button is pushed, the red LED will go off and the green LED will turn on. Since the diode is fast acting, this circuit will also detect momentary outages in the nanosecond range.

Basic Oscillator

Being similar to the Tunnel Diode in many respects, the Lambda Diode will also find many applications as an oscillator in af, rf, and dc-to-ac converters as shown in Fig. 8. Since the diode is so efficient, it draws very little current and consequently there is very little internal heating of the device. This results in excellent temperature stability, and it's a natural as the basic active element in a vfo or local oscillator.

Building a basic oscillator circuit is simple — all you have to do is add an LC tank circuit and a 6 to 12 volt power supply. The actual value of the supply voltage will depend on the particular JFETs you use to make up the Lambda Diode. However, the actual voltage is not critical as long as you bias the device in the negative resistance region of its characteristic curve.

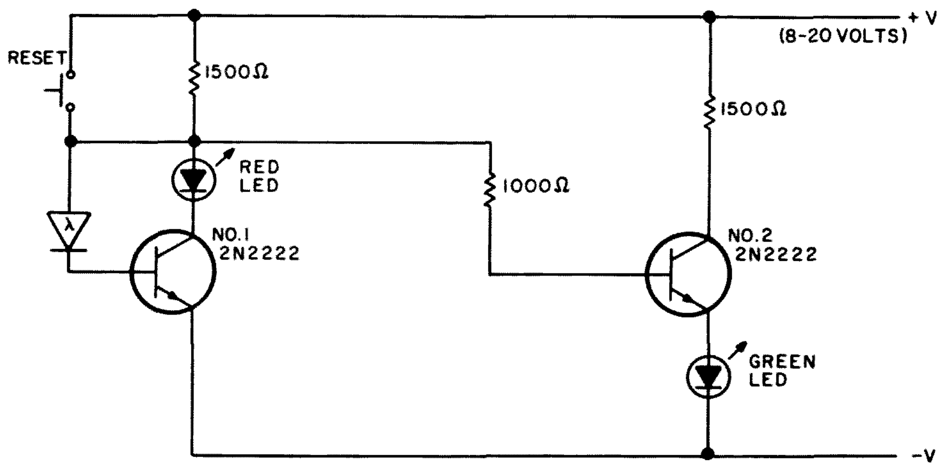

Fig. 7. Power failure monitor. This circuit will indicate a power failure on a bus between 8 to 20 volts. As long as this voltage is maintained, only the green LED will be on. If the power fails and is later restored, the green LED will turn off and the red LED will remain on until the reset button is pressed.

There are many applications for a simple oscillator of this type, from QRP transceivers to dip oscillators, signal generators, antenna testing devices, radio control applications and whatever you want to dream up. It's also possible to amplitude modulate the device, with a tone or voice, with excellent results. Although I have not tried SSB or FM with the device at this time, I feel reasonably sure that the oscillator will work here, too.

Since the Lambda Diode maintains an almost infinite impedance in its valley region, very little energy will be absorbed from the tank circuits. This is the basic reason why the Lambda Diode is so efficient as an oscillator and can produce an output amplitude voltage of twice the supply voltage. Also, because of its efficiency, the output amplitude will remain constant over its operating frequency range, even when the capacitance in the tank circuit is varied to change the frequency. This feature alone would make the device an excellent choice for a dip oscillator circuit.

Future Possibilities

Being a relatively new device, the potential applications are just beginning to emerge. Experimentation is presently being conducted on combining the Lambda Diode with other devices, as well as connecting two devices in series with similar polarity orientation (and also with opposing polarity orientation). The characteristics produced by such circuits are proving to be very interesting.

There is also the possibility of using the diode as the basis of a new memory cell which is only two-thirds the size of conventional CMOS memory cells. Since the Lambda Diode operates as a flip flop, only one bit line is required to activate the cell. By incorporating two additional MOSFETs, a new CMOS memory cell can be made using a total of four transistors as opposed to the six now required for conventional memories.

Regardless of how the Lambda Diode is used, it is evident that this versatile device is capable of performing many useful tasks. How well we use it will depend on our own ingenuity. ■

Mechanical RTTY Buffer

--using a tape punch and a clock

If you are active at all on amateur radio teletype, it is almost certain you have seen someone sending with that nice, even tempo which usually means he is using a buffer of some sort between his keyboard and transmitter. Recently there has been a fine solid state device for this purpose described in the *RTTY Journal.*[1] However, if you are interested in a cheap and dirty way to get the same type of transmissions, this article is for you.

Referring to Fig. 1, you can see it is really a simple device. It uses one of the NE-555 solid state timer chips, and very little else. What we have is actually a free running multivibrator, the speed of which can be varied. The one I built will go down to about one character every fifteen or twenty seconds, all the way up to full machine speed. There are provisions made for bypassing the buffer entirely, also.

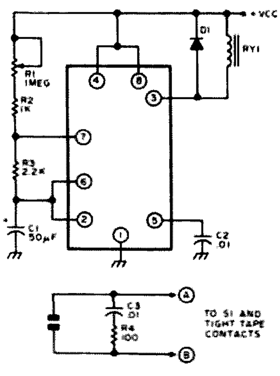

Fig. 1.

R1 is the speed control, R2 is necessary to prevent exceeding the voltage rating of pins 6 and 7, and R3 determines how long the relay will hold in. This can be varied to suit your own needs; the higher the resistance of R3, the longer the relay will hold during each pulse. This time period must not exceed 163 milliseconds, if using 60 words per minute (45.45 baud). If this period is exceeded, more than one character will be tripped off at a time.

RY-1 is any relay which will operate on the voltage you are putting on the NE-555. In my case, it is a six volt dc, single pole, single throw relay – a cheap one I had in the junk box. The filter across the contacts of the relay is used to cut down on the arcing while the buffer is in use. Since you are switching 115 V ac, there is quite a bit of arcing if this is not used, and the contacts will not last as well.

The output of the buffer is connected in series with the tight tape contacts in your transmitter-distributor (T.D.). This allows these to remain in the circuit just in case you set the speed of the buffer too high and the T.D. catches up with the tape you are sending.

Construction is by no means critical. I built mine on perfboard, but a small printed circuit could easily be fabricated. Mine is bolted to the inside of the model 19 table, using standoffs, with the control switch and speed control pot through the side of the table where they are easily accessible.

This unit can be used with any automatic send-receiver (ASR) machine. Set the keyboard for "tape only," and get enough slack in your tape to feed the end into the T.D., under the tight tape control rod. Turn on the switch which activates the pulser and set the speed control to a point where you can at least keep up with the sending rate. If you are far enough ahead, you can backspace and correct errors before they are sent. Your machine will now transmit smoothly and steadily, and your printer will show what is sent, and when.

By using this method you have one advantage over the solid state unit. That is, you have a tape of what you have sent in case QRM takes out a lot of it, and it can be sent again, either slowly or at full machine speed. The mechanical buffer is a bit noisy, but it does the job. Mine has been in operation for several months without any problems.

Fig. 2 is the simple power supply I am using. The NE-555 only requires about 3 milliamps, so the rating of the transformer is almost entirely dependent upon the current requirements of the relay you use.

My thanks to Bob Crumley K4DXR, who gave me the original idea for this unit, and for his encouragement to build it. ■

Have You Used a Triac Yet?

-- nifty solid state ac relay gadget

It's easy to switch dc off and on with a transistor, but what do you use to switch ac? A relay would work, but this is bulky, and consumes power to perform its work. An SCR would work, except that it can only conduct for about half the applied sine wave, resulting in half voltage being applied to the load. Or you could use two SCRs, connected back to back. However, this configuration is already available in one package known as a triac.

A triac is much like an SCR, except that it will conduct for very near 360 degrees. Triacs have three terminals, normally called Main Terminal One, Main Terminal Two, and Gate. MT1 and MT2 can be considered the normally open contacts of a relay, and the gate the coil of that relay. (Figs. 1 and 2.)

To activate the triac, trigger current is applied to the gate. This current can be either polarity dc or ac. Once the triac has turned on, current on the gate can be reduced to a much smaller value, called holding current. MT1 and MT2 will remain "closed" as long as gate current is at least this value. If gate current is removed, MT1 and MT2 are again isolated.

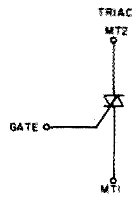
To operate a triac as a switch, we want it to be on for 360 degrees of the applied sine wave ac. For this condition, gate current must be at least the value required to operate in mode III positive. For instance, the RCA type 40668 is rated at 8 Amps, 200 volts rms, and requires 80 mA gate current for this mode.

Let's suppose we have built a high power linear amplifier, complete with safety interlock switches. These could be small microswitch types, wired as in Fig. 3. Resistor R is found by dividing gate current into gate voltage. Before the switch is closed, gate voltage will be 120 volts. Using 80 mA for gate current, we get a value of 1500 Ohms for R. To be on the safe side, use five to ten times the required gate current, or one fifth to one tenth the value of R. In actual use, any value from 100 to 500 Ohms will work well.

If R is replaced with a photocell, the triac can be turned on with a beam of light. When the cell is dark, its resistance is high, typically 1-3 megohms. When in bright light, the cell resistance drops to somewhere around 150 Ohms. A small lamp, taped tightly to the cell, will allow full isolation of the signal voltage from the triac and ac being switched. Any CdS cell will do, and suitable small lamps, called grain-of-wheat lamps, can be found at most hobby shops. See Fig. 4.

The lamp could be driven by a small signal transistor in your terminal unit, and the triac could directly switch ac to the TTY motor, for auto-start. A switch could parallel the photocell to allow running the motor as in a local loop.

Fig. 1. Triac symbol.



It is generally a good idea to put a resistor and capacitor in series across the main terminals of a triac to suppress any transients caused when the triac fires. Those transients could cause the triac to switch on or off randomly, or give sporadic operation. Ten Ohms and a .01 cap will do quite well, although these values aren't critical. These are only a

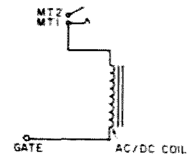


Fig. 2. Electro-mechanical equivalent.

couple applications for triacs. They can be used anywhere a relay could be used, and are priced low enough to be competitive with a relay capable of handling an equivalent current. Of course, they have no moving parts, are small and light, and are well suited for printed circuit board applications.

For much more detailed information on theory of operation, and ideas for zero voltage switching and light dimmer circuits, consult the RCA manual, "Thyristors, Rectifiers, and other Diodes." ■

Ham Help

I am greatly frustrated!!! You and the locals in Lafayette, Ind., are always trying to increase the numbers of amateur radio operators. Well, I used to be a Chicken Bander with bootlegging capabilities using a Siltronix 1011C and a Tempo One that had been converted for CB band. Those days are over with; all I have now is a Yaesu FR-101S receiver with all the bands plus 2 & 6 meters. So I did two more things. They are as follows:

1. Subscribed to your funky magazine.
2. Bought a U.S. callbook.

After monitoring 80 and 2 meter bands and logging a lot of local ops, I looked them up in the callbook. Then I would match the list with the local telephone book. And I was shocked to find with a lot of them that they were too busy, not at home, etc., etc. Excuses, excuses; wake up Lafayette, Ind. This kid wants to join the ranks of an amateur. I think I am getting the point across, but I guess the point is not motivating the amateurs in Lafayette, Ind. With Godspeed, I hope I can say that I am an amateur in the near future.

William A. McQueen
1419 South Street
Lafayette IN 47905

I will shortly be receiving my Novice license and I would like to hear from other hams concerning indoor antennas to be used in apartments where no balcony is available. I am not allowed to string any outdoor antenna systems. I would appreciate a sketch of any appropriate antenna capable of working on 80, 40, 15, and 10 meters.

I will be running 180 Watts and will have a transmatch available for matching to my transceiver. I hope someone has some good suggestions for me.

I would also like to be added to the list of ham helpers. I will give anyone help in code or theory. I have a B.S. in electrical engineering and my code speed is about 15 wpm.

Thank you very much. I think Ham Help is a very good idea.

Another CW Keyboard Keyer

-- CMOSed for ultra low power consumption

R. L. Way WA9VGS
12116 W. Belmar Drive
Hales Corners WI 53130

The TTL mechanized keyboard keyer previously described by W9UBA and WA9VGS* has been carried a giant step forward by K6BS (formerly W9HI). Ern liked the simplicity of the Keycoder I design, but wanted a completely self-contained unit with very low battery drain for mobile and portable CW use. So he remechanized Keycoder I with inexpensive and readily available CMOS logic elements and obtained the following results: 7-8 microamps of power dissipation during keyer operation, and a few tenths of a microamp during the quiescent state (there's no "on-off" switch in his unit). Ern reports that he's still using the same 9 volt transistor battery that he installed in October, and that it's still reading 9 volts (mid-March). Useful battery life should about equal the shelf life of the battery.

The elimination of an ac power supply in this CMOS keyer, of course, means less weight, less space required, less building time, and, most important, fewer dollars to build. Also, with no ac leads coming into the unit there is even greater immunity to rf interference (K6BS operates a kilowatt and has had no rf problems).

As shown in the schematic diagram, the circuit operation is practically identical with that of Keycoder I, so only the differences will be commented upon here. Observe that pins 4, 5, and 6 of U7 (top left of diagram), and pins 11, 12, and 13 of U7 (to the right of the SCR Q1), are shown as inverters. Actually, these are 2 NAND gate sections of a quad 2-input NAND gate element (CD4011); they function as inverters in this circuit (the inputs of each section are tied together), so are shown as inverters.

*73, July, 1976.

The 22k and 10k resistors and the 0.22 uF capacitor in series with each other across the 9 volt transistor battery provide a bit of transient filtering for the 9 volts, and the resistors also serve to limit current through the SCR. The diode connected to the junction of the resistors gives a small amount of feedback around the SCR, and may not be needed, depending upon the particular SCR and R and C values you use.

The dot generator is a relaxation oscillator consisting of two sections of U7 (top left of schematic) with RC feedback. It works like this: In the quiescent condition, the logic states are as shown on the schematic, and the 0.27 uF capacitor is fully charged. When pin 1 goes high, pin 3 goes low, and pin 4 (the dot generator output) goes high, starting the first dot. With pin 3 low, the capacitor starts to discharge toward that point, but does so relatively slowly due to the large resistances in the discharge path. When the capacitor has discharged sufficiently, the voltage at pin 2 falls below the input threshold of the gate, causing

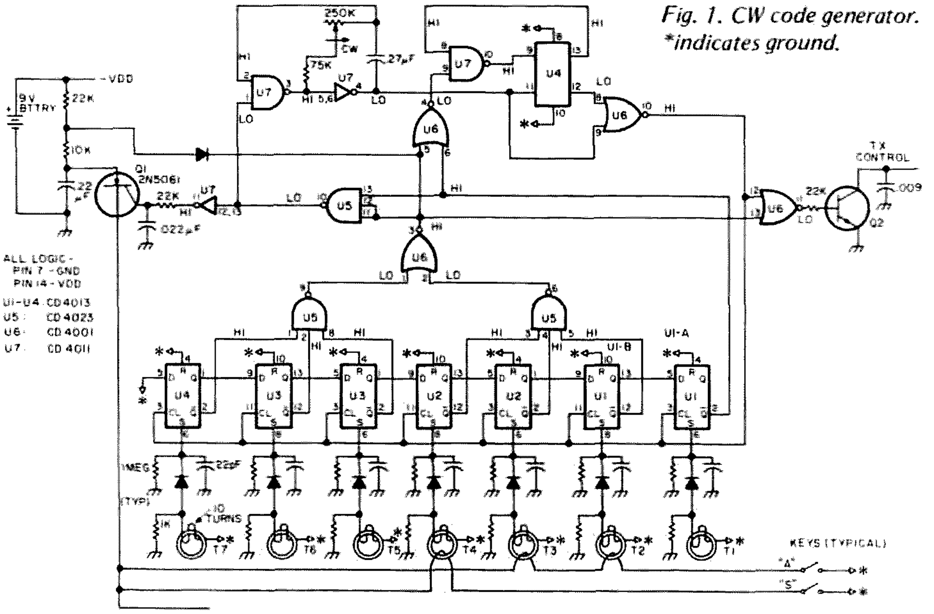

Fig. 1. CW code generator. *indicates ground.

pin 3 to go high, and pin 4 to go low, completing the first dot. With pin 3 high, the capacitor starts to charge again, but again takes a finite time to do so because of the large R. When the capacitor charge reaches the input threshold of the gate, pin 3 goes low again, and the cycle repeats, as long as pin 1 is high.

In order to further conserve microamps, and because all his rigs have sidetones, K6BS did not include a monitor in his CMOS keyer, but the above dot generator circuit could easily be duplicated, with appropriate changes in R and C values, to provide a code monitor; only one additional 29¢ element would be required.

The core matrix circuitry is a little different than that in the TTL Keycoder. First of all, the logic is reversed since CMOS flip flops are set with a logic "1", rather than with a "0". Hence, the core secondaries are connected to ground, and phased such that a positive spike is generated when a key is closed and the SCR fires. As with the original Keycoder, the phasing of the cores can be determined experimentally during construction. The 1k resistors from the core secondaries to ground are for loading, and 1k is simply a nominal value. Because of the extremely high input resistance of CMOS elements, all pins must be terminated to prevent self-oscillation and resultant thermal runaway. Therefore pins 6 and 8 of the CD4013 flip flops (U1-U4) are connected to ground through 1 M resistors. The 22 pF capacitors stretch the extremely rapid input spikes from the cores into 10 usec wide pulses to set the shift register flip flops.

NPN transistor Q2 can be selected with sufficient drive to work with either of the output schemes discussed in the previous article. ■

I/O EDITORIAL

HALF A COMPUTER

Most of the ads for computers are written for knowledgeable computer fanatics, not beginners. Thus there is a certain lack of candidness as far as the software involved is concerned. Newcomers may be vaguely aware that software is needed for computers, but not really understand just how important it is . . . particularly for the neophyte . . . to have some sort of operating system available.

Like several thousand others, I read the early MITS ads and envisioned myself sitting down to a small computer system (golly, the board is only $425 in kit form!) to play games, keep track of DX stations worked, find out when Oscar would come into range, and things like that. Naive Wayne.

For several months my Altair 8800 microcomputer was a fantastic $2000 coffee table conversation piece. I could hold visitors spellbound with tales of the marvels of this great device and the things it would be able to do. Note that "would be able." About eight months into my ownership of the 8800 I received a cassette with BASIC language on it . . . and a brief instruction manual. About three months later I cheered one night when, after a great many tries, the system suddenly came to life and BASIC loaded and was usable. Now I could start to learn programming.

This is not to in any way put the Altair down, for the ignorance was mine about the importance of software for almost any applications of the system. And while MITS was optimistic about when it would have a BASIC interpreter ready for delivery, their optimism has been a model of rectitude as compared with some other microcomputer manufacturers. In case there is any question in your mind, I think the rule of thumb is that hardware takes about twice as long to get into production as expected by the manufacturer and software about four times . . . if they are lucky.

One of the more frustrating things about reading ads for microcomputer systems is trying to figure what configuration you will need and what programming is really honestly available right now for it. For instance, when I visited Sphere back in August, 1975, they were expecting to ship hardware within a few weeks and were certain they would have BASIC available for it in the same time slot. I think the hardware finally got out in about four months (complete systems, I mean) and to my knowledge they have not yet shipped BASIC in any good usable form.

Sphere did have a version of BASIC which they started to send out, but my understanding was that it was one which had been written for a minicomputer system and had then been adapted via an interpreter to the Sphere. The result was a verrry slooow system. Back to the drawing board.

The last I checked there was no BASIC available as yet for the Wavemate (Jupiter) system.

Southwest Tech has come up with 4K BASIC and an 8K BASIC. The 4K is free with the M6800 system and the 8K costs about $10 extra . . . not a bad deal at all. At first SWT wasn't going to get involved with programs, but now they are sending the 4K BASIC to all owners.

Imsai does have BASIC available . . . either on paper tape at $4 for the 4K version or $8 for the 8K version. Both are available on PROM, and this has an advantage of being in such a configuration that it can be used right from the PROM without having to take it off into a RAM memory before it can be used as the new Altair PROM BASIC requires. The cost is not inconsiderable, however . . . about $500 for the 4K BASIC with PROM and board and double that for the 8K system.

Having the program on a PROM is a big time-saver, because then you don't have to sit and wait for BASIC to be loaded into the system every time you start it up. With RAM memory you either leave the system turned on permanently or else you go through the long loading procedure every time. PROM looks very good to you along about the twentieth time you have to load up.

Speaking of prices, the Altair BASIC on cassette, if you buy your memory from MITS, costs about $75. Bargain. Oh, you pay a little more for their memory boards, but then you can't do much without that BASIC, so the extra expense seems reasonable.

If you are into computers and programming, you may not care whether BASIC (or any other high level language) is available. Not that any others are really available as yet, practically speaking. I've seen ads for FORTRAN for the Altair, but since the ad was from a software house I'll bet they want an arm and a leg. I note that Dick Whipple (you've been reading his articles) programs in machine language and likes it. Of course, most of his programs have been process and haven't really called for the time savings of a higher level language. I suspect if he wanted his system to sit there and compute the square root of a long list of numbers that he might want to insert BASIC or FORTRAN.

If any readers have more information on this whole subject, their articles will be appreciated. There are thousands out there who know many times as much as I do about it, and I'm ready at any time to step off my podium and make space for them.

The thrust of this message is to read the fine print carefully when you are shopping for a computer system. I think you are going to want BASIC for your system, so make sure you know where you can get it . . . and how much it is going to cost.

If any readers think that they are going to order hardware and get a computer system up and working without learning a lot, they have another think coming. These are in no way black boxes as yet. Even brand new assembled boards from the factory may sit there and not work, and you will have to be able to troubleshoot them. You'll have to find out which chips or parts of chips on your memory boards are not remembering. You'll have to find out why in the devil the program you have so painstakingly put together gets dumped into nowhere when you thought you were merely putting a copy of it on a cassette and saving the original in memory. Etc10.

Have fun.

BEEFS

A letter from WA3LWR in Scranton is typical of perhaps a half dozen received in recent weeks. It will come as no news flash that I am oversensitive to criticism and feel that I have to justify myself. This is no exception. Bob complains that *73* was once a ham radio magazine, but now is filled with computers and too few general interest articles. Possibly.

If you happen to feel likewise, I would appreciate not only hearing from you, but getting a detailed review of your reaction to the articles chosen for each issue. Take the August issue, which apparently sparked Bob's complaint . . . it starts out with an article on ICs (p. 24) – I assume there are still amateurs who are so locked into tubes that they are trying not to learn about ICs, but since ICs are one of the most fundamental building blocks for most current ham circuits and virtually all in the future, would *73* be a responsible publication if it turned down articles such as this? The DDRR antenna (p. 28) – isn't that hammy enough for you? The keyer (p. 38) might not have interested you before July 23rd if you are a Tech, but now that you have Novice frequencies you'll be wanting to build a good keyer, and this is a good one. The breadboard article (p. 52) would not interest you if you don't build, but since over 80% of the hams today build . . .? The audio generator (p. 56) would interest those into FM, RTTY, SSTV and control circuits, and hopefully that includes a lot of hams. Golly, you *must* be interested in *something* other than rag chewing! If you don't build, the Logic Grabber would not interest you (p. 60). And the DX article (p. 68) would be of most interest to DXers. I love DXing, don't you? The counter calibrator (p. 70) should interest any builder or counter user . . . how can you get along without a counter? I use mine virtually every day of the week for something. The 450 rig doesn't grab you? A lot of chaps are active on the band . . . and ATV is flourishing with the pioneers. Now, even if you are not a pioneer type, you recognize your dependence on them to keep amateur radio going. Are you going to try to force magazines not to publish articles to spur pioneering? That seems counterproductive. If you are too busy to do the work, at least don't try to prevent others . . . okay? Now we're into the so-called I/O or computer section, starting with a fantastic story by WA8VNP, a youngster who is the epitome of what amateur radio is all about. Oldsters with firmed up minds would do well to read Don's article. What was *your* reaction to it? (p. 82) The chip (p. 90) and languages (p. 98) and arithmetic (p. 108) are an effort to provide fundamentals in this new field . . . and they are difficult to get *anywhere* else. Baudot (p. 102) is for RTTYers mostly. The Logic Probe (p. 106) is needed in almost every ham shack these days. Satellite orbits (p. 113) . . . hammy? Only if you are into Oscar . . . and you *should* be. A couple more RTTY articles (pp. 122 and 150) . . . one on logic (p. 116) . . . a signal tracer (p. 148) . . . true, there isn't much for the rag chewer and we did antennas so much in June that many readers are still in wire shock.

What do *you* think about the content of *73*? I know that only a small percentage of readers are yet into microprocessors, just as very few readers were into FM back in 1969 when I started making information available on repeaters. I don't see how uP can have any less impact on hamming than FM . . . and FM is the single most active mode today in amateur radio. I'd appreciate your opinions . . . but please be specific and cover every article in an issue, not just a general impression . . . okay?

I/O REPORT

by John Craig

The New Magazine

The machinery has been set in motion for starting a new computer-oriented magazine later on this year. I should point out that it isn't going to be just another magazine in the field, either . . . it's going to be the *best!* Our main thrust will be in the area of *applications.* We're going to have articles on both hardware and software, and they'll be written with examples and applications we can all relate to.

I'm sure that everyone who has become involved in personal computer systems has heard (time and again) the question, "What are you going to do with a home computer?" My standard reply to that question is, "It's my toy, and I have a lot of fun playing with it." Deep down inside I know full well that it's destined to be more than a toy.

Someday, in the not too distant future, there are going to be a lot of people taking a second look at the "monsters" they've created and realize these computer systems could be *making some money,* too. (Extra cash is something most of us don't find objectionable, right?) If you think you've heard some good application ideas so far, just wait until the small business ideas start flying around! And just wait until you see how our new magazine covers those (and many more) applications!

Speaking of Money-making Ideas . . .

The other day a friend of mine, who is a professional programmer, stopped by for a chat and came up with an interesting proposal. He suggested that the two of us pool our resources and go into a part-time business doing accounts receivable, inventory, and payroll for doctors' offices. (He felt it would be best to concentrate on just one type of business in the beginning.) His proposal was this: He would develop the software to make such a system possible and I would provide the hardware for running it. The system would be cassette-oriented, in that the doctors' offices would have a data-entry terminal for entering all transactions, inventory flow, etc. The purpose of the terminal would be to record all of these transactions onto the cassette . . . which we would pick up each evening for processing at home.

At the moment there are two or three obstacles to be overcome before such an idea could become a reality. A floppy disc would be most desirable, to say the least. (Or would you believe a 52 megabyte IBM cartridge-type disc for $375.00??) The item which is really holding things back is a low cost key-to-tape data-entry terminal. I sure wish someone would get busy and develop it. It wouldn't have to be very sophisticated; the main thing would be to provide a display (perhaps just three or four lines by 32 characters) so the operator could check the entry before writing it out to the cassette. A keyboard, display, cassette recorder, and the interface electronics would be the basic elements. (And how about for under $150??) Just think about it for a moment . . . this little terminal could be used in just about *any* business! Sound interesting? Good. Why doesn't somebody get busy on it . . . line up a manufacturer to put out a kit . . . and we'll publish it all in *73?*

The Sherick DG System.

Responsible Applications

We all get junk mail. As a matter of fact, some of the junk mail we get these days is generated by computers. I don't have anything against this stuff . . . it's simply too easy to throw it away if I don't want it. I recently heard about a computer application involving *junk phone calls,* and that *does* bother me. Something like that is getting very close to what I would call "invasion of privacy," and I have the feeling a lot of other people will feel the same way.

The idea centered on the development of a system which would generate "sales pitch" phone calls for a real estate company. Using an optical reader, the computer would scan through pages of the phone book and call prospects within the immediate area of the real estate. It was estimated that if only a small percentage of the calls resulted in sales the system would pay for itself.

A lot of people either have a fear or a distrust of computers, and I would hope that the evolution of the home system might help to eliminate this somewhat. Receiving junk phone calls from a computer will probably turn some of that fear and distrust to anger. This isn't going to help us in promoting personal computer systems, and, who knows, it might even lead to legislation prohibiting such activities. And, as someone else pointed out, "The biggest problem here is that I'd have to go to the trouble to program my computer to answer your computer!"

The June SCCS Meeting

Erich A. Pfeiffer (Ph.D. and WA6EGY) gave a very interesting talk on the history of computers and microprocessors. (Be sure to catch his article in the August *73* on building the MINI-MOS Keyer.)

As usual, the meeting was attended by several hundred (two or three, at least) computer enthusiasts. The exhibitions, displays, and selling areas took up three full rooms. The rest of the country has to wait around for the next computer convention . . . we have one here in Southern California every month!

The Talking Computer

One of the second prize winners (there were two) at the MITS convention back in March was Wirt Atmar and his talking computer. He has since decided to market the hardware/software package and has made some interesting discoveries as a result of his efforts.

It seems that his machine has somewhat of a "computer accent" and is most easily understood by young children and people who have traveled and been exposed to different dialects and accents. The talking also seems to be easier to understand when it is being used during the playing of games. But perhaps the most interesting point was the fact that a person had to *want* to understand the machine. Those who approach it with a negative attitude in the beginning seem to be the ones having the greatest difficulty understanding it.

Wirt is going to be selling the package for around $400. They're going to be sold only through computer stores around the country. That way a person will be able to go in and hear it before he buys it. He could build a unit that would sell for around a thousand dollars, and would be more easily understood than the present one, but he feels that is out of the range of the average hobbyist.

Writing for 73

Wayne and I mention writing articles so often that it must seem like we're really in a rut. Not so. We just know a good thing when we see it. And I mean a good thing from your angle. To heck with the fame and recognition . . . we pay out large quantities of U.S. currency for good articles.

If you don't care about the money or fame, then let me appeal to your "responsibility" to share some of the things you've been doing with your system that others may not have the know-how to accomplish. There are a lot of people out there doing a lot of exciting things. Unfortunately, they aren't taking a little time to tell the rest of us about them. If you are one

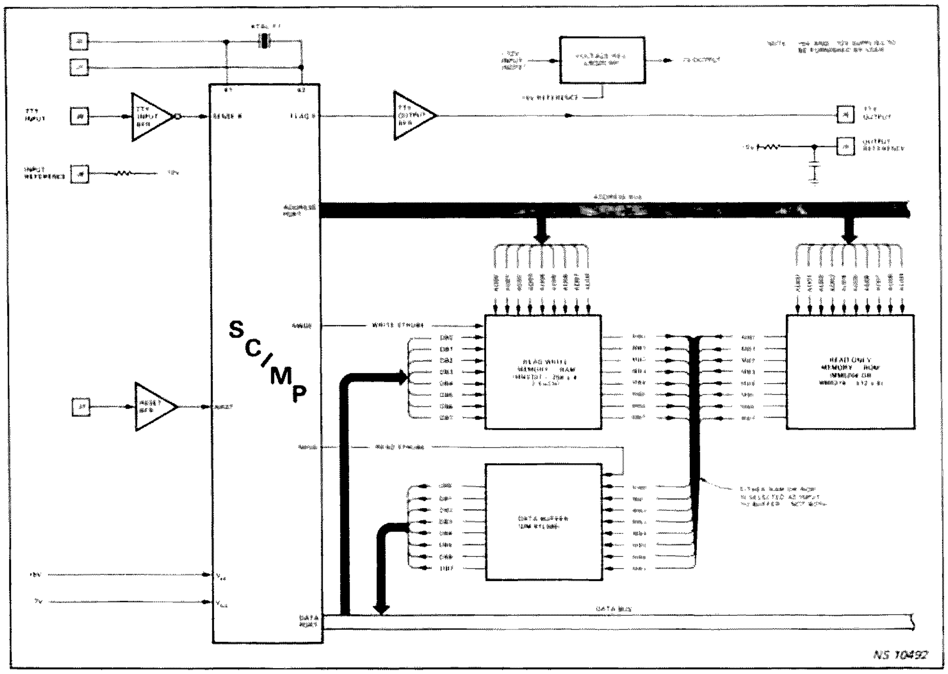

Fig. 1. SC/MP kit block diagram.

of those people . . . give it some thought, OK?

What would happen if . . .?

Here's something for you to think about. What do you suppose would happen to this home computer "movement" if some large company with a lot of advertising bucks came out with a *system* and began advertising it on nationwide television? I'm thinking in terms of a "turn-key" home system. The average layman could purchase it at his local computer store (or local Radio Shack outlet?), cart it home, plug it in, load a program into it from cassette, and have it start doing things. (Actually, that last point may be the big stumbling block for this whole scheme. Are there that many practical *things* the home computer can now do that would make it appeal to the average layman?)

Let's assume that a salable software package was developed by some company, such as Radio Shack. I'm sure you've all seen some of Radio Shack's impressive ads on TV for their CB and stereo units. What if they used that same tasteful (and sophisticated) approach for convincing Mr. and Mrs. America that the "Realistic Home Computer System" was something they couldn't live without?

If the price were right and people started buying their package, the spin-offs would be incredible. Most importantly, the entire country would be aware of the coming of the home computer . . . and a lot of people would do some shopping around. And even if the Radio Shack system were built around a little-used chip like the Fairchild F-8, there would soon be a lot of companies jumping on the bandwagon developing and marketing memory and peripherals for the system. Also, as more people become involved in this thing, it should mean a lot more software being developed for everyone (at least, I sure hope it turns out that way).

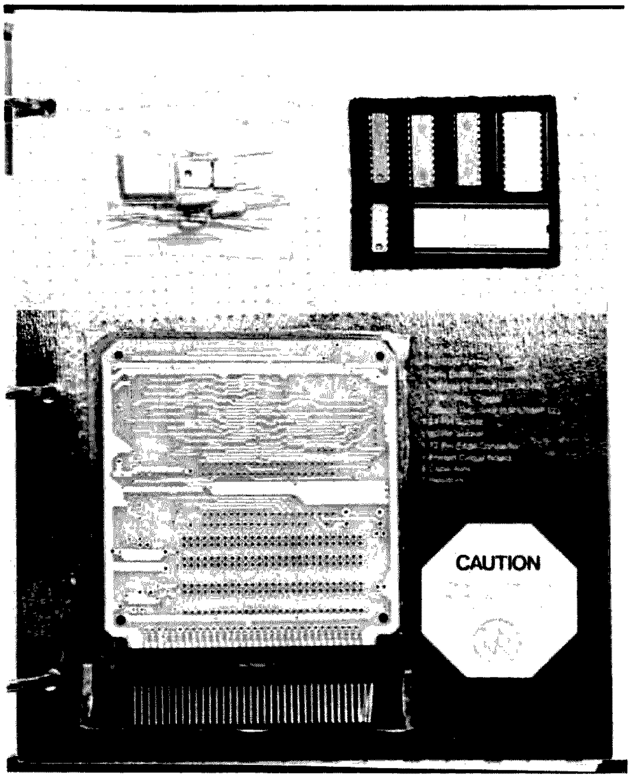

Photo 1. The SC/MP kit upon arrival.

The Sherick DG System

Mike Sherick, of Vandenberg AFB, California, was only recently bitten by the bug. After attending several meetings of the local computer club (Central California Computer Users' Group . . . at the Cabrillo Computer Center . . . home of the *Micro-8 Newsletter*), he decided on a Digital Group System. He chose the Digital Group System for a couple of good reasons. The first was the fact he had seen how easily a friend's (Sam Daniels') unit was brought up and became operational with very little difficulty. The second reason was that Sam is an extrasharp programmer type, and the two of them decided to team up and work to their mutual benefit.

Mike is a professional photographer with a long-standing interest (and involvement) in electronic experimentation. The "experimenting" has certainly carried over into some of the things he is doing with his home computer system, too. For example, that front panel is far from being a standard item from the Digital Group (they provide the plans for it, but that's all). Mike became convinced of the value of a good front panel for hardware debugging and development (and software debugging) and set forth to build a real beaut.

Notice the bottom center switch on the front panel. It's labeled "PROM," "RAM," and *"PRAM."* Mike built an interesting modification into his system, which allows him to have page zero as the DG operating system PROM, or as RAM in the form of 2102s, *or both at the same time* (PRAM). The purpose of this mod is to allow loading of programs into page zero (which is normally occupied by the PROM). Through software manipulation, the two areas are operated in "simultaneously", i.e., the loading program is being accessed in PROM (page 0), and the new program is being loaded into the RAM in page 0. Whew! I wasn't sure I was going to be able to explain that! Future plans include the building of a variable step and examine rate feature, and mounting the entire unit into a modern brushed aluminum cabinet which is going to make us all drool. (We'll have to be sure to get a photo of that one, too.)

Mike got into this hobby because he has a curiosity and a desire to learn about computers. It's just a shame that his lack of experience has inhibited him so much!

We would like to see other systems from around the country in *73*. Take a picture of it (8 x 10, B/W) . . . with you, too . . . send along a little write-up . . . and we'll let the world know what you're doing. OK? And I'd especially like to see some good ham applications.

NEW PRODUCTS

National's 8-bit Microprocessor Kit — SC/MP

National Semiconductor has made the plunge! Their 8-bit SC/MP (originally called "SCAMP") microprocessor has been out for some time now, but apparently some new marketing strategy has developed and they're now offering it in a package for $99.00. That price, and what it buys, is something for the hobby community to sit up and take notice of, too.

When the SC/MP kit arrived, we opened the box and the only thing in there was a notebook! The first reaction was that somebody goofed and

forgot to include the computer. But, it turns out they have a rather neat packaging scheme and the components are mounted on cardboard and located in the notebook (under, of all places, a section entitled "Components"). See Photo 1. The notebook contains a very thorough collection of manuals covering the kit and its construction, technical description, and programming.

The kit itself consists of a printed circuit board, 72-pin edge connector, discrete components (resistors, capacitors, crystal, and voltage regulator), and the SC/MP microprocessor and support chips (see Fig. 1 for a block diagram of the SC/MP kit). The support chips include a pre-programmed 512 byte Read-Only Memory which contains KITBUG (a monitor/editor for program development), and 256 bytes of RAM. A TTY interface is also included on the board (a $99 computer ... and a $1500 TTY!).

The SC/MP microprocessor has a complement of 46 instructions (both single and double byte). The chip has an internal clock generator which requires only an external capacitor or crystal. A serial input and serial output port are provided, along with two sense inputs (one which doubles as the interrupt input) and three control outputs. These control outputs can be used for external control of such things as relays, solenoids, external lights, and alarms. The chip requires +5 volts and -7 volts (which is derived, in the kit, from -12 volts being applied to an LM320 voltage regulator).

Fig. 2 illustrates how the separate serial and input lines can be used to implement parallel-to-serial (and vice versa) transfers under SC/MP control. This is just one of several application diagrams included in the documentation. They also provide circuits for building a front panel and a hexadecimal keyboard interface (which would be considerably less expensive than a TTY).

One of the interesting possibilities offered by the SC/MP is its use as a central I/O controller in a microcomputer system. Imagine having small routines in PROM which would handle data transfers to and from a cassette, to and from your TV Typewriter, and output to a low cost printer. These routines could be developed using RAM memory, and after dubugging could then be transferred into PROMs (with appropriate address modifications made . . . which hopefully, would not lead to further debugging being needed). The SC/MP PROM (a 5204) can be programmed by your local National distributor, Bill Godbout Electronics, or Morrow's Micro Stuff for a nominal fee. (See the Godbout and Morrow's ads in this issue of *73*.)

Programming the SC/MP is accomplished using the KITBUG monitor/editor. KITBUG has a grand total of three commands: T, for "typing" out the contents of memory (i.e., a memory dump); M, for "modifying" individual memory locations; and G, for "go" (begin program execution).

We happened to have a power supply (which provided the necessary +5 and -12 volts) mounted in a small cabinet. There was just enough room for mounting the SC/MP kit, and Photo 2 shows the neat package we came up with. The "system" consists of a master reset switch (top center), power on/off switch ("operate"), four connections to the ASR/33, and the +5, -12, and ground connections. Note that space is provided on the PC board for mounting additional components for a particular application.

The SC/MP kit does not lend itself to much in the way of memory or I/O expansion. However, National does offer three application modules for those with a desire to build a larger system around the SC/MP. These include a CPU PC board, RAM memory board, and a ROM/PROM board.

National offers applications and programming training for the SC/MP (and their other microprocessor systems, including PACE) at their training centers in Santa Clara CA, Dallas TX, and Miami FL. They also sponsor COMPUTE (Club of Microprocessor Programmers, Users, and Technical Experts) which is "a user group dedicated to the worldwide distribution of ideas and techniques relating to the use of microprocessors." Members communicate through the *Bit Bucket*, a newsletter published by National Semiconductor. One of the neat things about COMPUTE is the user-submitted software library which has contributions published regularly in the *Bit Bucket*. It's a pretty good bet that it won't be too long before some user contributes a SC/MP version of Tiny BASIC!

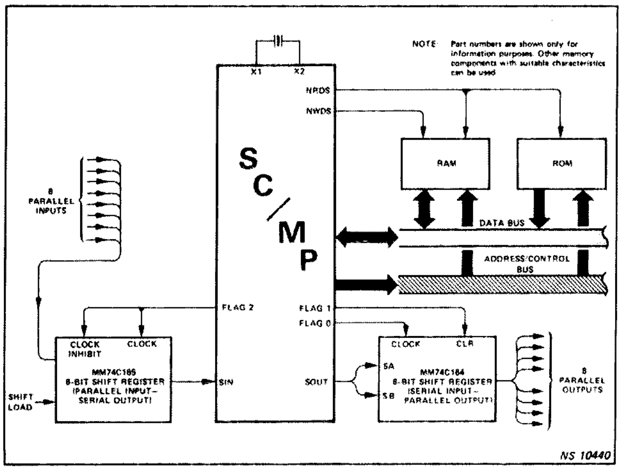

Fig. 2. Using SC/MP with a simple serial interface.

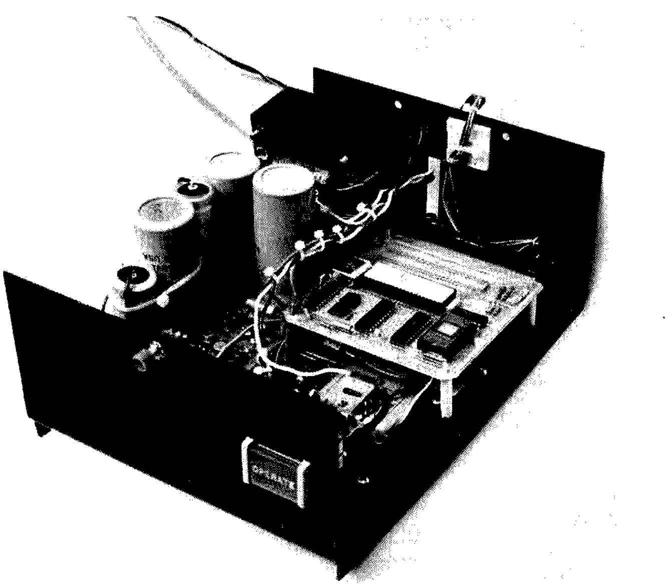

Photo 2. The completed SC/MP kit "system."

The SC/MP kit single unit price is $99.00. To order, or obtain further information, contact: National Semiconductor Corporation, Mail Stop 520, 2900 Semiconductor Drive, Santa Clara CA 95051.

The Tarbell Cassette Interface

There have been a lot of companies in recent months that have jumped on the bandwagon in providing plug-compatible accessories and options for the Altair 8800. Tarbell Electronics should be put up toward the top of the list of those providing *quality* units.

The unit can be purchased either in kit form or assembled. Audio and ribbon cable is provided for the Altair and cassette recorder interfacing, and a sync tape is included for initial checkout. The manual supplied with the unit contains a wealth of information. Aside from the assembly and checkout instructions, circuit theory of operation, operating tips, troubleshooting, and application ideas, there is an abundance of software. Routines are included for input and output transfers, cassette bootstrap, and sync code generation; most importantly, modifications to MITS 8K and 12K BASIC are also included, so either one can be loaded or saved using the Tarbell interface. Another significant offering in the software area is a mini-operating system (Processor Technology Software Package #1), which has file handling capabilities (SEARCH for a particular file, MOVE it from one area of memory to another, COPY from one cassette to another, SKIP a file, and more). The cassette also includes an assembler and text editor. It is available free with a $5 handling charge for listings and instructions (if you desire them also).

The interface was designed to achieve speeds up to 540 bytes per second (2200 bits per inch), but the normal operating speed is 187 bytes per second. This corresponds to the ANSI standard of 800 bits per inch. By modifying the oscillator frequency and performing a parallel-to-serial conversion in software, the interface can also be used for program exchange using the Kansas City standard. The manual makes the point that, "Since the standard is fairly slow, it suggests that many people will want to have two methods available: one which provides for program exchange with other hobbyists around the country, and another which is much faster, so that program loading and development can be speeded up." Since a great deal of time is going to be spent saving and loading data, programs, and other text, the speed will definitely become an important consideration. You need to decide if you want to have enough time to stand up and stretch while loading BASIC at 187 bytes/second (40 seconds) or have time to jog around the block while loading at 30 bytes/second (*4 minutes*).

The encoding technique used in the Tarbell interface is quite simple and has been in use throughout the industry for quite some time. You can visualize this technique if you imagine a shift register filled with data. The register is clocked with a square wave and the output data is exclusive-ORed with this square wave. This results in a

RTTY/uP Flexibility

-- Baudot/ASCII serial/parallel I/O

The next two construction articles in this series allow your RTTY/Computer Display System to be hooked to serial data lines, either ASCII or Baudot, rather than having to accept parallel ASCII. This feature can prove very useful if the display unit is very far away from the data sending unit (keyboard or computer).

Both projects fit on a small (less than 4" x 4") board and connect to the main board with a dual ended DIP plug. They allow simple selection of a crystal controlled baud rate by setting eight inputs to the board high or low according to a formula. Each uses a UART, which makes reliability high and keeps the number of components low.

With the main board and either one of these optional input boards, you have a very powerful display terminal easily switchable between different codes and formats.

This month the ASCII input will be discussed, while next month the Baudot article will be presented.

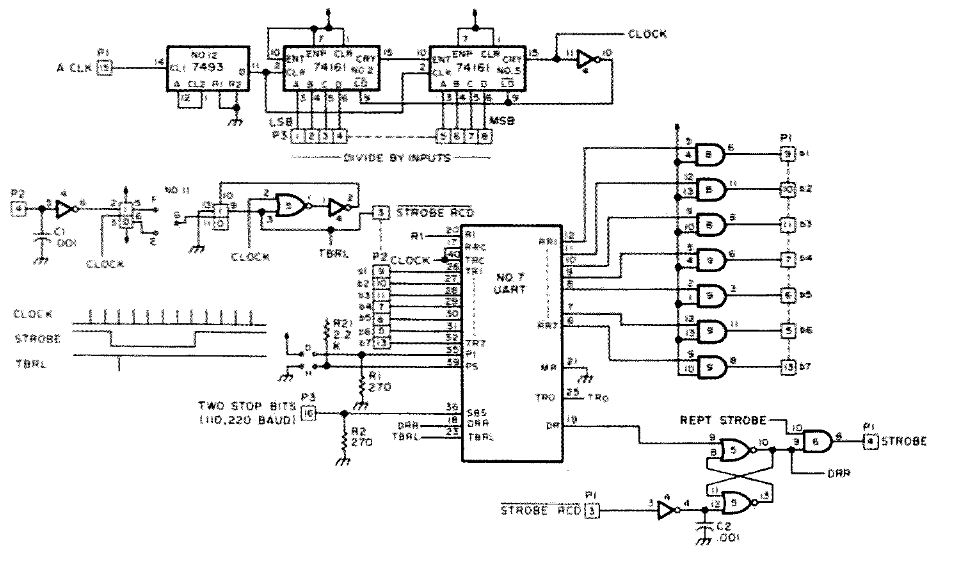

Fig. 1. Jumpers: D — parity inhibit; H — odd parity; E-G — positive strobe, F-G — negative strobe.

Figs. 1 and 2 are the schematic diagrams for the serial ASCII input option. This option is used to convert serial ASCII to parallel, or take parallel data from a keyboard and serialize it. The major device used is the UART, which changes the data's format while converting from serial to parallel (or vice versa).

The UART requires a clock at 16 times the baud rate, which is made by two divide by N counters. The counters each have four inputs, which control the number of divisions the counter has (from 1 to 16). The formula for setting these inputs is:

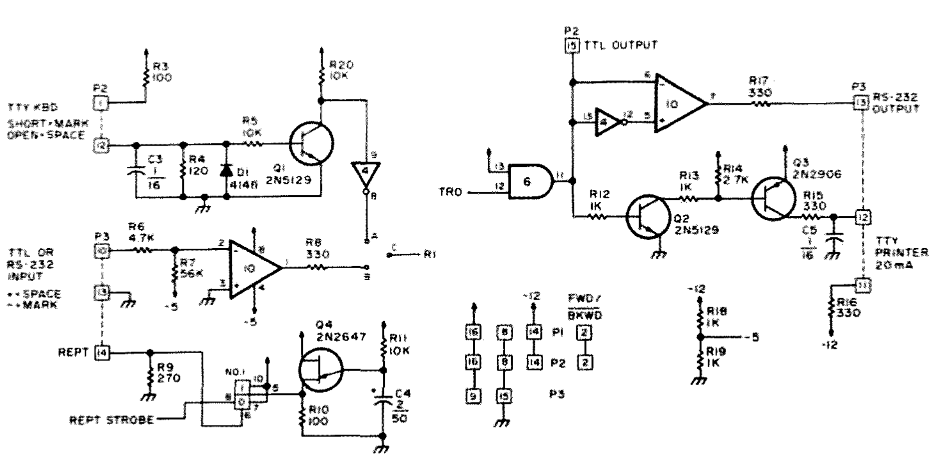

Fig. 2. Jumpers: A-C — TTY keyboard operation (input); B-C — RS-232 input.

$$256 - \frac{380,160}{16 \times \text{baud rate}}$$

Note that the number must be converted to binary to set the inputs. Therefore, for 110 baud the setting would be:

$$256 - \frac{380,160}{1760} = 40 =$$

0010 1000
msb lsb

The inputs to the two counters appear at eight pins of the P3 plug, and can be hardwired to the determined setting or run to a switch where several speeds can be selected. Jumper settings for several common baud rates can be found in Table 1.

The output of these dividers (circuits 2 and 3) is pin 15 of circuit 3, and is sent to the UART clocks, pins 17 and 40.

The serial input data can take any of three forms: TTL, EIA, or 20 mil loop. If it is TTL or RS-232 (EIA), it is fed into an operational amplifier which inverts it. If a 20 mil loop is used, the outside world simply opens and closes the circuit between pins 1 and 12 of plug P2.

If these contacts are shorted, current flows through the 100 and 120 Ohm resistors, causing a voltage drop across the 120 Ohm. This voltage drop is fed through a resistor to turn transistor Q1 on, grounding its collector. This brings pin 8 of circuit 4 high — which is a mark condition to the UART. If the two terminals are open, no voltage drop will appear across the 120 Ohm resistor, and the transistor will stay turned off. This will bring 8 of 4 low — a space condition to the UART. Either the output of the op amp or the inverter can be jumpered to the UART serial input, with B-C being the op amp and A-C being the loop input.

This data is fed into the UART, and is converted to parallel there. The parallel output is buffered by circuits 8 and 9, and the data ready line (pin 19) goes high when the output data is stable. This line sets a flip flop (pin 9 of 5) which brings 10 of 5 low. This is sent through an AND gate to the display unit as the strobe line. It also goes directly back to the UART to acknowledge the data ready line.

When the display unit receives the strobe, it enters the data into memory and sends back a strobe received pulse. This resets the flip flop, causing strobe to go away. The UART is now ready to receive another byte of data.

If data from a keyboard is to be serialized, the parallel data is presented at the UART, pins 26-32. If you don't want parity sent with the data, jumper D. Likewise, if you do want parity sent, don't jumper points D. Then jumper or leave H if you want odd or even parity, respectively. The strobe pulse from the keyboard is debounced by the .001 disc capacitor and the first half of circuit 11. The output of this flip flop is sent to the clock of the next one. When this goes high, the second flip flop's output goes low. This is ORed with the clock, so that the next time the clock goes low, the flip flop will be preset. The series of events for the strobe input is shown in Fig. 3.

Pin 9 of 11 is the strobe received pulse sent back to the keyboard, and also loads the data into the UART. After the load pulse goes away, the data is sent out pin 25 serially.

This output is buffered at pin 12 of 6 and is sent to the three different outputs. It is sent directly to the TTL output, but is buffered to +5 and -5 volt swings at the other half of the operational amplifier (circuit 10) for the EIA signal. The signal is also sent to a 20 mil loop switch, transistors Q2 and Q3. With the output high (mark), transistor Q2 is conducting, which grounds its collector. This turns on transistor Q3, which allows loop current to flow. If the output is low, Q2 is cut off leaving the base of Q3 high — also cut off. No loop current flows.

The -5 volt supply to the op amp is derived from a resistor divider from -12 V to ground, since -5 V is not sent from the main board to the ASCII input.

If "rept" is brought high, the clear line of circuit one is brought high, allowing its output to oscillate. This output is fed to the AND gate used for the strobe pulse — causing the strobe line to the display unit to oscillate. It should be noted here that even though the data ready line of the UART may have been reset before, the outputs are still available.

Assembly

Refer to the first four paragraphs of the main logic board's assembly procedure for basic information per-

Speed (Baud)	Divide By Decimal	Binary msb lsb
110	40	00101000
220	148	10010100
300	177	10110001

Table 1.

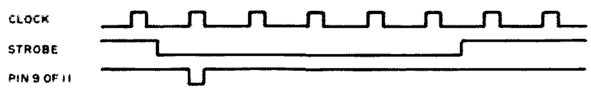

Fig. 3.

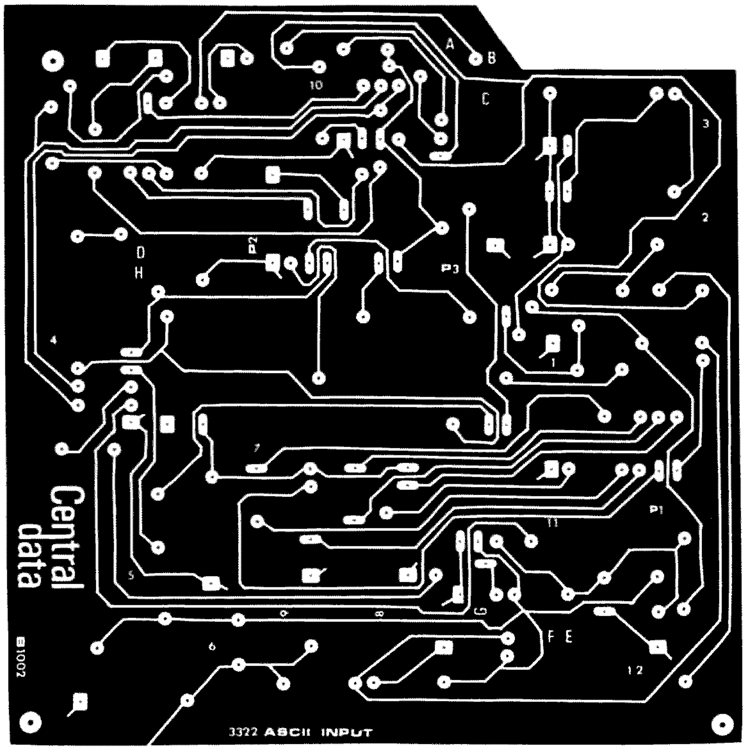

Fig. 4. PC board.

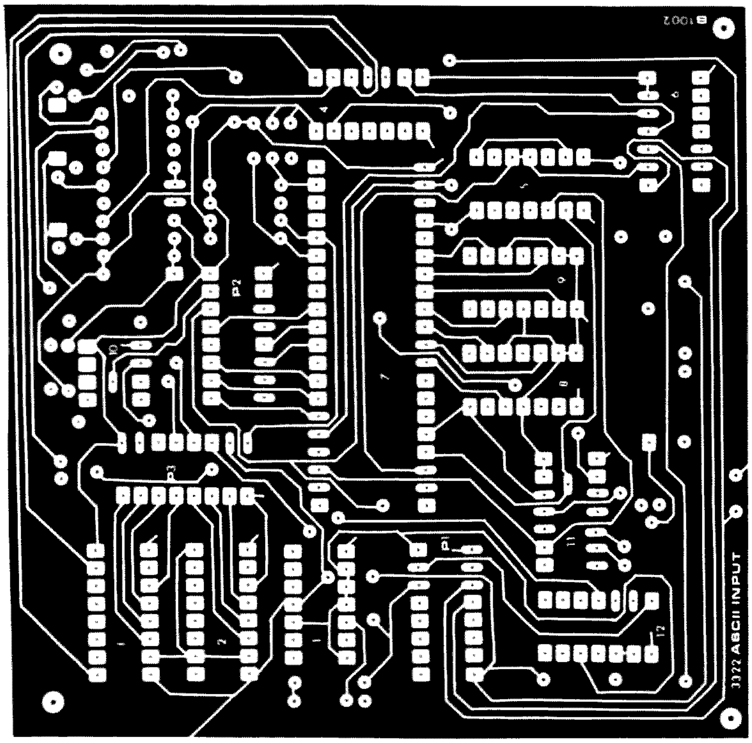

taining to the assembly of this unit. Fig. 6 is the placement drawing for all of the components on the ASCII input board. All parts have part numbers and component numbers (as used in the schematics) printed on the drawing.

1. Mount and solder all resistors and diodes to the board. The banded (cathode) ends of the diodes are marked with a square pad on the top of the board. Mount all of the components before soldering, as a way to check your work.

2. Mount and solder the 40 pin socket and the three 16 pin sockets at the positions marked UART, P1, P2, and P3, respectively.

3. Mount all of the TTL integrated circuits on the board and after checking their placement, solder them in. The placement of pin one is denoted by a small "flag" coming off of that pin's pad – along with a square pad on the top of the board.

4. Plug the 40 pin UART into the socket, being careful not to bend the leads.

5. Mount all capacitors and the transistors, being sure to polarize the electrolytics. The square pad on the top of the board denotes the positive end of the capacitor and the emitter of the transistor.

6. If parity is not to be sent, jumper D. If you want to send parity with the serialized keyboard data, jumper or leave H depending on whether you want odd or even parity, respectively.

7. Jumper E-G if your keyboard strobe pulse is negative going. If it is positive going, jumper F-G.

8. If you are using TTL or EIA RS-232 inputs, jumper B-C. If, however, you use the loop input, jumper A-C.

Operation

Connection of the serial ASCII input board to an external keyboard, modem, and main logic board is done by way of 16 pin DIP sockets and associated plugs. The cable with two DIP plugs is used to connect the two boards together, the input socket of the main board to P1 of the option board. There are two remaining cables, one shipped with both the main and the option boards.

Other
7-.1 disc capacitors
1-2 uF/15 V electrolytic capacitor
1-.001 disc capacitor
1-40 pin DIP socket
3-16 pin DIP sockets
1-DIP plug with cable
1-double ended KIP plug
1-circuit board

A kit of the above parts is available from:
Mini Micro Mart
1618 James Street
Syracuse NY 13203

One of these cables goes from P2 to a parallel ASCII keyboard and/or the circuits associated with the loop input and the TTL output. The pin designations for plug P2 are:

1 – loop input +
2 – fwd/bkwd (to P1)
3 – strobe received
4 – strobe
5 – b6 (keyboard data)
6 – b5
7 – b4
8 – Ground
9 – b1 (keyboard data)
10 – b2
11 – b3
12 – loop input –
13 – b7 (keyboard data)
14 – -12 V
15 – TTL output
16 – +5 V

The other cable goes from P3 to the circuits associated with the TTL or EIA input, the repeat key, the EIA output, the loop output, and the speed selection switch (if any). The pin designations for plug P3 are:

1 – b1 (divide by N)
2 – b2
3 – b3
4 – b4
5 – b5
6 – b6
7 – b7
8 – b8
9 – +5 V
10 – TTL or EIA input
11 – -loop output
12 – +loop output
13 – EIA output
14 – repeat
15 – Ground
16 – Two stop bits

Fig. 9 of the main article shows the colors of the flat cable as they relate to the pins of the DIP plug.

The specifications for the input signals are:

Loop input: Mark = terminals shorted; Space = terminals open.

Loop output: Mark = 20 mil current flowing; Space = 0 mil current flowing.

TTL or EIA input: Mark = .8- -15 V; Space = 2.4-15 V.

TTL output: Mark = 0-.8 V; Space = 2.4-5 V.

EIA output: Mark = -3- -15 V; Space = +3-+15 V.

To connect the ASCII input board to a full duplex, 20 mil loop teletype (KSR-33 or ASR-33), follow the schematic in Fig. 5. ■

Blowtorch Your ICs

--a bonus from computer surplus

Have you ever tried to remove 14 or 16 pin DIP ICs from surplus computer boards? Sometimes this can be a very exasperating job, and you may even pass up some good bargains because you don't want to go through all the trouble of removing them.

There are many ways to remove ICs. You can use a special tip that heats all the pins at once, you can clean the solder off the pins one at a time, you can use a special tip with a vacuum line attached, or you can even use a special tip with a blower attached. All these methods are slow, cumbersome, and expensive, and you will usually end up wishing you had three hands to accomplish very much.

The method that I use may shock you a bit at first, but believe it or not, it really works well.

I remove ICs from surplus computer boards with a blowtorch. That's right, a propane torch that can be obtained in just about any ham's workshop.

I turn the flame on the pins from the circuit side of the board and yank the IC out (fast) from the component side of the board using an IC puller or just a plain old pair of pliers. Even when using the torch running full blast, I have yet to damage an IC due to excessive heat. Excessive heat seems to be an old wive's tale on some of these modern ICs. Of course you can't reuse the boards. ■

How to Interface a Clock Chip

-- Baudot, BCD or ASCII conversion

This circuit was developed as the result of a need to interface a clock chip to some other hardware. Unfortunately, the clock chip available had only 7-segment output, and was not equipped with BCD outputs. The first solution required a relatively large number of gates, and because of space restrictions, was inconvenient for the project in hand. To overcome this problem, the gating was replaced with a 32 x 8 PROM, addressing the PROM from the 7-segment output of the clock, with the BCD stored in the appropriate locations of the PROM. Fig. 1 illustrates the segment designations of a 7-segment display.

Since the PROM is 32 x 8 bits, it has only 5 address lines, and it is therefore impossible to use all the clock outputs. But if the 7-segment coding for the numerals 0-9 is considered (Table 1), it can be seen that it is still possible to obtain a unique code for each numeral, by using only segments a, b, e, f and g. If segment a is considered as the most significant bit, and segment g as the least significant bit of a 5 bit natural binary code (used to address the PROM), then the ten locations listed in Table 1 will be addressed for the numerals 0-9. These locations contain the BCD code.

Although the solution was satisfactory, there is a considerable amount of unused space in the PROM, and since it was desired to link the clock to a microprocessor-based RTTY system at a later date, it was decided to see if any of the remaining locations could be used to contain ASCII or Baudot coding for the numerals 0-9. The first to be dealt with is Baudot. If BCD and Baudot are compared (Table 2), it is very clear that element "B" of the BCD is identical to element "E" of the Baudot, except for the numeral 1. If it were not for this one difference, it would be possible to store the BCD (4 bits) and the Baudot (5 bits) in the 8-bit word of the PROM. This problem was overcome by the addition of a 7410 triple 3-input NAND to the output of the PROM, as shown in Fig. 2. Then, in any given word of the PROM, the BCD is stored in bits 0-3, and elements A, B, C and D of the Baudot are stored in bits 4-7. Thus all the BCD and elements a-D of the Baudot are directly available at the output of the PROM, and element E of the Baudot is obtainable from the extra gating, which works as follows. If the output of U1 is high, then the output of U3 will follow the input of U2 (element B of the BCD). But if at any time the output of U1 should be low (which will happen for numerals 1 and 7), then the output of U3 will be forced high. The output of U3 can then be used as element E of the Baudot. Thus the aim of encoding both BCD and Baudot is achieved, and they are available simultaneously.

Obtaining the conversion to ASCII was accomplished in a totally different way. It was necessary to modify the address inputs in some way,

Numeral	a	b	c	d	e	f	g	PROM location addressed with segments a, b, e, f, g. (Decimal)

Table 3. 7-segment code, with a, b, e and g inverted.

so that the 7-segment would address another set of unique store locations. The only modification of the address inputs which can be done easily is controlled inversion. With the aid of a computer, all the possible combinations of inversion of the address inputs were checked, from which it was discovered there were two. And for reasons which will be given later, the following was chosen. By inverting segments a, b, e and g from the clock, the locations listed in Table 3 can be addressed, and it is in these locations that the ASCII (or any other code) is stored. The inversion is carried out with a 7486 quad exclusive OR, as shown in Fig. 2. If point X in Fig. 2 is brought high, then segments a, b, e and g of the clock are inverted, and ASCII can be obtained from the outputs of the PROM; if X is at logic low level, then the outputs obtained from the PROM will be Baudot/BCD.

The circuit given will function perfectly well with any 7-segment coding which produces a 6 without a top, and a 9 without a tail. Since some clock chips produce the 6 with a top, and a 9 with a tail, this was also given consideration. And this is the reason that of the two possible combinations of inversion of the input to the PROM, the one given was chosen. Since the tail of a 9 is given by segment c, it will have no effect anyway. But the top of the 6 will affect the most significant bit of the PROM address line, and it is necessary to allow for it. All that is required is to repeat the BCD/Baudot for the numeral 6 in another location of the PROM, and the same for the ASCII coding of the numeral 6. This information is given in Table 4.

Thus it can be seen that with the addition of 2 extra packages to the PROM, it is possible to cater for the conversion of 7-segment to ASCII/BCD and Baudot, with or without topped 6s and tailed 9s. A complete summary of the layout of the PROM is given in Table 5.

Although this conversion was designed for use with a clock chip, it could be equally well used to convert the output of other chips, such as digital voltmeters, to another code.

The PROM used was a 6331 from Monolithic Memories, but a Signetics 8223, which is easily obtainable, can be used instead. Instructions for programming the 8223 are given in the January 1976 edition of *73*, in the article "The Computer QSO Machine," by B. D. Lichtenwalner. ■

Hey, Look What My Daddy Built!

-- six TV game chip can make you a hero

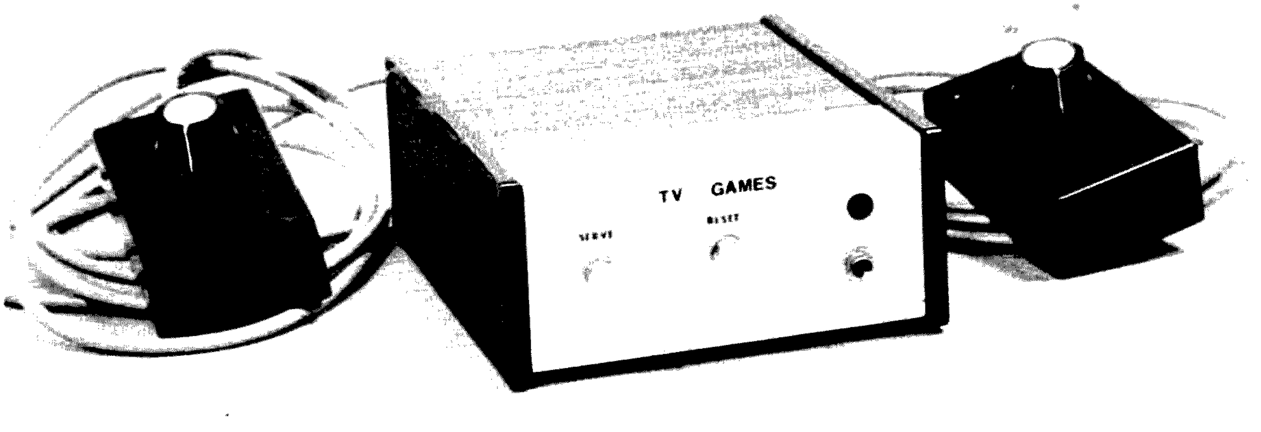
"Wilbur, can't you keep those damn kids quiet while I'm making dinner?" How many American husbands have heard that? If this were the opening block on the "wordless workshop" home improvement cartoon feature found monthly in *Popular Science* magazine, the next six cartoon blocks would illustrate the construction of a giant bird cage or ski jump for the backyard to entertain the kids. This is a nice idea, but there are very few things which are universally entertaining to children, or adults for that matter – except maybe the boob tube. Today's generation of children has grown up spending more time in front of a television than in school. The TV has become a cheap babysitter and the primary source of entertainment for most American families.

Wilbur, trying to keep peace in the family, scans the TV listings and sees that he has a choice of Peyton Place reruns, a subtitled movie in Swahili and Jimmy Durante doing impressions of Walter Cronkite. His only wish at this point is that the TV set would show something that he wanted rather than what Smell-o Deodorant or Slippery Lip Ice Cream was willing to sponsor.

Wilbur checks his *Popular Science* and considers the cartooned suggestions, but decides that he might enjoy the bird cage idea too much and the ski jump would attract more noisy kids. In his continuing search through the magazine rack, he spies an article describing the construction of a TV ping pong game and decides this may be the answer to his problem. Such a system would use his existing TV – no re-education necessary – and all parts are available from a supplier listed in the article.

Wilbur spends his $140 and obtains a kit by mail a month later. He carefully lays out all the parts for the basic game plus the optional scoring board and power supply: 90 TTL ICs, assorted resistors, capacitors and hardware. His wife surveys this and pipes in with, "Do they sell that junk by the pound?"

Completely undaunted, Wilbur spends the next week, three telephone calls to the kit manufacturer, and one very expensive and frustrating visit to a TV repairman for him to set and align all the timing circuits. The kids have been thoroughly entertained in the meantime watching



Game circuit built by author.

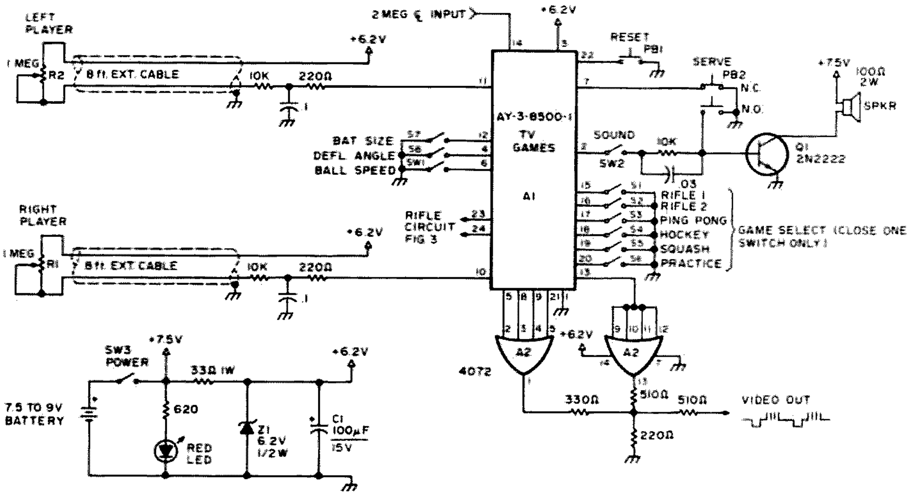


Fig. 1. TV game schematic.

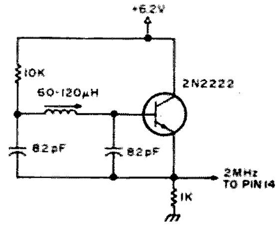

Fig. 2. 2 MHz oscillator. Miller 9055 miniature slug-tuned coil; all resistors ¼ W 5%; all caps min. 25 V ceramic.

Daddy cuss each individual component as he assembled the massive board.

Then came the moment of truth. Power on. It would be unfair to say that it didn't work. It did work and the kids were completely occupied for about three weeks. They then got tired of just bouncing the ball back and forth in the same ping pong game all the time. "Wilbur, can't you keep those kids quiet while I'm making dinner?" ARRRRG!

This painfully familiar story serves as our introduction to the world of TV games. There are TV games sold in every discount store and almost every major electronics periodical has had a construction article on them. The commercial units cost between $75 and $100 and the construction kits are about the same cost, but there are considerable differences among them. Some may be using older designs which may have as many as 100 chips to perform only one game, or at the other extreme one chip to perform six games. Obviously, Wilbur would have been better off buying a unit which performed more than one game and allowed variations within each. Fewer parts would necessarily mean a lower price and increased reliability.

The ultimate in perfection (so far) is the subject of this article: the AY-3-8500-1 made by General Instruments. This is a 24 pin MOS integrated circuit TV game chip capable of playing six different TV games. The features are as follows:

1. Six selectable games — tennis, hockey, squash, single player practice, and two rifle shooting games
2. Automatic scoring
3. Score display on TV screen: 0-15
4. Selectable bat size
5. Selectable ball speed
6. Selectable deflection angles
7. Automatic or manual ball service
8. Realistic sounds
9. Shooting forwards in hockey game
10. Visually defined playing area for the four ball games

Game Descriptions

TENNIS:

The tennis game picture on the TV screen will be as shown in Fig. 5. There will be one bat or player per side, a playing field boundary and a center net. Scoring position is as illustrated. After reset is applied, the score is 0 to 0 and the ball will serve arbitrarily from one side toward the other. It is the opposing player's objective to intersect the path of this ball and deflect it back toward his opponent. If no intersection occurs, a point will be automatically scored against the erring player and the ball will again be automatically served toward him again. Serve will not change until he scores a point and gains the advantage. A game concludes when one player's score totals 15 points.

The exact details of the game are a function of the optional speed, size, and

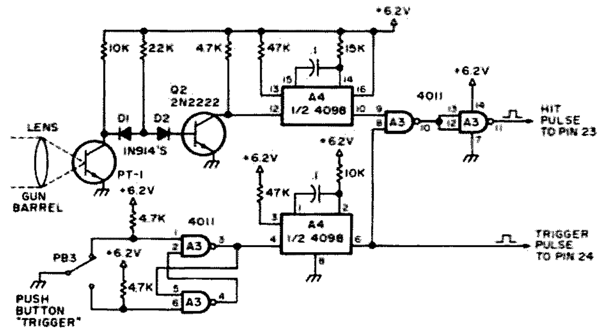

Fig. 3. Rifle circuit. PT-1 — phototransistor TIL64 or equiv.; 4098 — dual monostable; 4011 — quad 2 input NAND; all resistors ¼ W 5%; all caps min. 25 V dc ceramic.

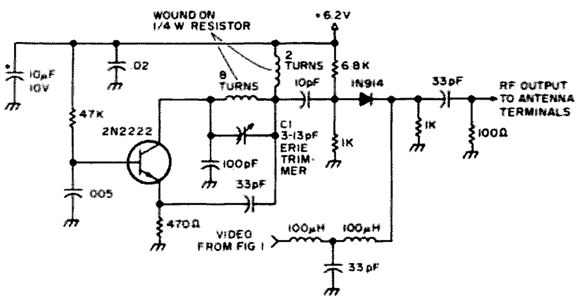

Fig. 4. VHF modulator sample circuit. All resistors ¼ W 5%; all caps min. 25 V ceramic unless otherwise noted. NOTE: THIS IS AN ILLUSTRATION OF A SAMPLE VHF MONITOR. THIS CIRCUIT HAS NOT BEEN APPROVED BY THE FCC.

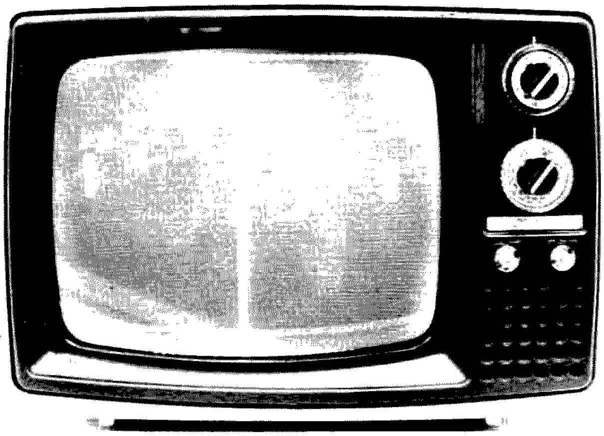

Fig. 5. Tennis game with ball in play.

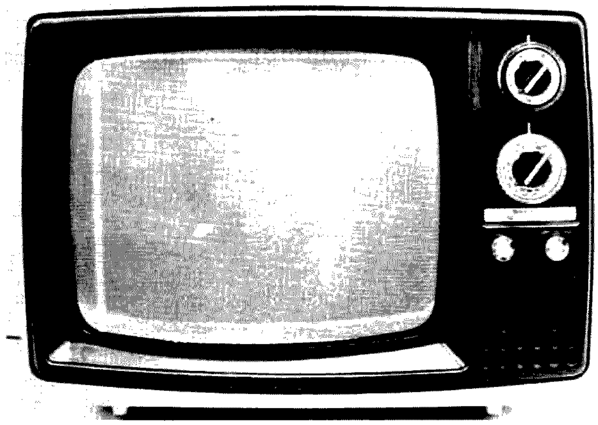

Fig. 7. Squash game with ball in play.

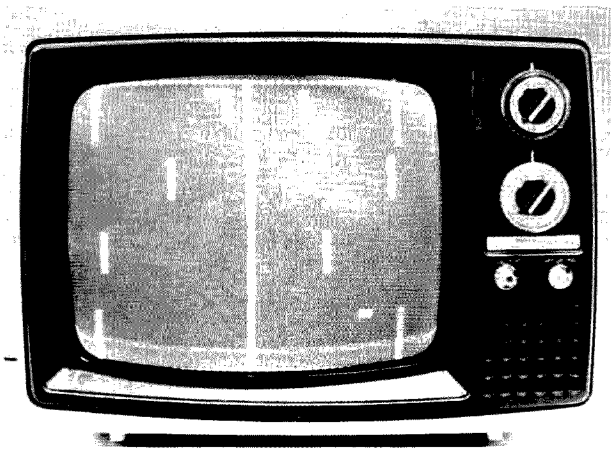

Fig. 6. Hockey game with ball in play.

angle selections. While the game is in progress, three audio tones are output to indicate boundary reflections, bat hits and scores.

HOCKEY:

The rules of the hockey game are exactly the same as the tennis game except that each human player controls two bats or players on the screen. These players shown in Fig. 6 are referred to as the goalie and the forward respectively. The goalie defends the goal, while the forward is located in the opponent's playing area. When the game starts, the ball will be arbitrarily served from one goal toward the other side. If the opponent's forward can intercept the ball, he can shoot it back toward the goal and score a point. If the ball is missed it will travel to the other half of the playing area and the opponent's forward will have the opportunity to deflect the ball toward the goal. If the ball is "saved" by the goalie or it reflects from a boundary, the same forward will have an opportunity to again try to deflect the ball back toward the goal. This method of jamming the ball between the forward and the goalie is a very effective scoring method and makes for an exceptionally exciting game.

Scoring and audio are the same as the tennis game.

SQUASH:

This game is illustrated in Fig. 7. There are two players who alternately hit the ball against a back court boundary.

Scoring and audio are the same as the tennis game.

PRACTICE:

This game is illustrated in Fig. 8 and is similar to squash except that there is only one player.

RIFLE:

The rifle game is illustrated in Fig. 9. Rifle 1 game results in a large target which randomly shoots across the screen while Rifle 2 requires that the target bounce around within the area defined by the TV screen. External circuitry listed in Fig. 3 conditions optical input to a photocell located in the barrel of a toy pistol or rifle which is aimed at this random target. When the trigger (PB3) is "pulled," the shot counter is incremented. If the rifle is on target, the hit counter is incremented.

After 15 shots the score is displayed.

Circuit Description

The simplest circuit utilizing this game chip is illustrated in Fig. 1 and shown in the photo. A DIP switch (S1-S8) is used for rarely changed functions such as game selection, rebound angle and bat size. A $2.00 eight section switch such as this serves to lower overall costs by replacing about $8.00 worth of toggle and rotary switches while maintaining miniaturization. S1 through S6 are the game selection switches. Only one of the switches is enabled or placed in the ON position. The others must be left open or the game chip will try to play more than one game simultaneously. The correct procedure for selecting a game is to turn the currently programmed game off (all six switches open) and then close the particular switch for the desired game. Switches 1 through 6 will select the following games respectively: Rifle 1, Rifle 2, tennis, hockey, squash, and practice.

Bat size and ball deflection angle are controlled by DIP switch sections S7 and S9 respectively. With S7 open the larger bat size is selected. On a 21" television screen this will appear to be about 2". When this switch is in the closed position, small bats of approximately half the previous size will be displayed. All paddle game photos in this article illustrate the large bat selection.

When first playing a TV game, a player may want to find his bearings and fine tune his eye-hand coordination. For just this reason General Instruments provided for selectable bounce, or deflection angles. When S8 is open, three rebound angles are enabled – plus and minus 20 degrees and straight back

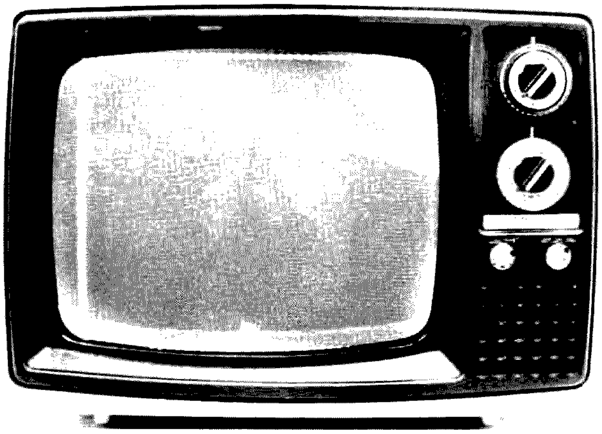

Fig. 8. Practice game with ball in play.

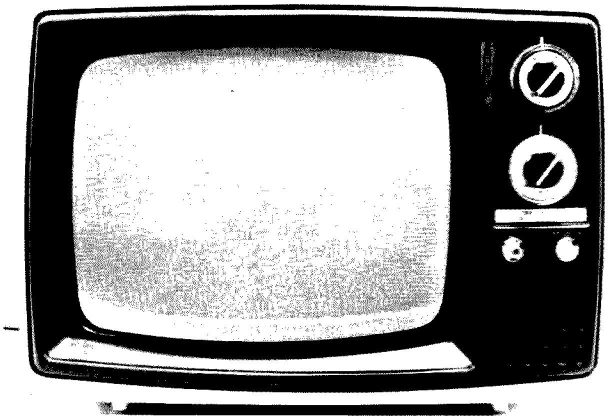

Fig. 9. Rifle games 1 and 2 target.

at 0 degrees. With S8 closed, five rebound angles are possible – plus and minus 20, plus and minus 40, and 0 degrees. This latter selection requires considerable player skill and dexterity and adds new dimensions to otherwise repetitious games. If that were not enough, selectable ball speed is also available. The ball speed switch SW1 is used more often than the game select switches and therefore should be a more easily used slide switch. When this switch is open, low speed is selected. In this mode the ball takes 1.3 seconds to traverse the screen. When the switch is closed, high speed is chosen and the ball will dart across the screen in .65 seconds. There is a complete understanding of the concept of human fallibility after playing a game which combines small bat size, full rebound angles, and a fast ball speed. With this combination, the cure for boredom becomes electronically induced insanity.

If these features were not sufficient, there are more – realistic sound and automatic scorekeeping. All games consist of 15 points with both players starting with a score of zero after pushing the game reset button (PB1). With pin 7 grounded through the manual serve push-button (PB2), play will resume automatically upon the release of the reset button. Automatic start is signified by the game ball being arbitrarily served into the playing area, and each time a point is scored, the ball will come into play into the court defended by the player having scored the point. If automatic start is not desired, the reset and serve buttons should be pressed simultaneously when resetting a game. The reset button is then released while still depressing the serve button. This will allow complete player readiness and will only put the ball in play when the serve button is finally released. Score is incremented (up to a high of 15) each time a player fails to deflect a ball away from goal.

All of this rebounding and scoring results in some very interesting game sounds. A ball hit upon a paddle results in 32 milliseconds of 976 Hz tone. A boundary reflection is 32 milliseconds (msec) of 488 Hz tone and score is 160 msec of 1.95 kHz tone. This square wave oscillation is amplified by a 2N2222 transistor and applied to a 100 Ohm .2 Watt speaker. (An 8 Ohm speaker may be used with proper current limiting in the collector circuit.) SW2 is provided to switch off the sound without having to shut off the game. Player positioning is remotely controlled through cables attached to pins 10 and 11 of the game

PB2	DPST momentary push-button C & K Subminiature
SW1, 2	SPST slide switch Alco Subminiature
SW3	SPST toggle switch C & K Subminiature 3 A 115 V ac
PT-1	TIL 64 phototransistor or equiv. Texas Instruments
D1, D2	1N914 diode Texas Ins.
C1	100 uF electrolytic 15 V dc
Z1	1N753A or equiv.
R1, R2	1 meg composition potentiometer 2 Watt Allen-Bradley or equiv.
SPK	100Ω .2 Watt speaker
LED	NSL5053 LED or equiv.

All resistors are ¼ Watt 10% unless otherwise indicated.
All capacitors are ceramic type with min. voltage ratings of 25 V dc unless otherwise indicated.

MISC	extension cable, batteries, box, hook up wire, etc.

chip. Each player control consists of a 1 meg pot and .1 microfarad capacitor which combines to form a variable time constant utilized by internal timing circuitry. Longer or shorter time constants will result in relatively different vertical player positions. To reduce noise, this extension cable should be shielded; otherwise, a display malady referred to as "herringbone effect" will result.

For a TV game to be properly displayed on a raster scan television, the proper video signal, similar to that of any commercial TV station, must be applied to the antenna. Such a video signal results from synchronized dividers inside A1, which divide the 2 MHz master clock (Fig. 2) and output the required 60 Hz vertical and 15750 Hz horizontal sync signals. These signals from pin 13 are combined with those of the ball output, right player output, left player output, and score and field output (pins 5, 8, 9, and 21 respectively) in a two bit digital to analog converter formed with a 4072 CMOS dual 4 input OR gate. This type of video output is referred to as composite video output and is suitable only for use on video monitors and not standard televisions. This video output may in turn be used to amplitude modulate an rf carrier suitable for a standard television receiver. Fig. 4 illustrates a sample circuit of this basic type of modulator. With the components chosen, the frequency is approximately that of VHF channel five. (This circuit is intended for illustration only and acceptability by the FCC as a proper class 1 rf modulator is not inferred.) The modulator output is connected directly to the TV antenna terminals, with the antenna disconnected, and adjusted for the best reception.

This game is a marvel of engineering ingenuity through which General Instruments has succeeded in enlightening the average American to the latest advances in electronic technology. It is easy to overlook 16K bit RAMs and microprocessors, but it is hard to ignore such a marvelously exciting TV game when presented on your own home television. ■

NEVER SAY DIE

EDITORIAL BY WAYNE GREEN

from page 4

system that is just like RTTY, but with the break-in feature.

If RTTY operators wanted to, they could have break-in just by setting up their systems on two different frequencies. Then they could use a split CRT display such as Don Alexander has developed (August, page 82), to show both what they are sending and what they are receiving on the top and middle of the tube. If anyone gets into this I'd like to know about it, and so would a lot of RTTYers.

Not a few readers would probably like some hints on how to get their code speed up to 100 wpm . . . any volunteers?

UNEMPLOYED?

The politicians are talking a lot about jobs, yet here at *73* we have jobs going begging. We need help in several departments and would be absolutely delighted to have some hams come up here to fantastic New Hampshire to join us.

If you read *Newsweek*, you know that New Hampshire has one of the lowest tax rates in the country, yet provides very good services for the people. It has one of the lowest accident rates in the country on its roads. This despite the large influx of visitors who come to New Hampshire on vacation . . . four seasons of the year. We have large vacation crowds in summer when it is cool and beautiful. We have them in the spring when it is fantastically colorful and fresh. We have them in the fall to see the finest foliage in the world (except for a small part of Northern China where they have similar acid earth which generates these colors) . . . and winter! Winter is the best season of them all . . . not too cold, but with snow for the many ski slopes.

For the ham, New Hampshire has two major advantages . . . one is rarity . . . New Hampshire has few people so you are almost like DX on many of the ham bands. And, if you are into FM, the myriad of mountaintop repeaters throughout the state will keep you busy. You will be hard put to keep from finding a mountain for yourself.

In southern New Hampshire we are not too far from Boston . . . for plays and concerts . . . and a major airport for travel. Yet we are in the country. Peterborough is one of the most beautiful towns in New England. Even though it is very small, it is a shopping center for this part of the state, with downtown shopping and two shopping centers on the outskirts of town.

We have grown considerably during the last year at *73* . . . with circulation up over 30% since January and headed for a 50% increase by the end of the year. Advertising has increased almost 50% in the past year. The staff has almost doubled and there is still a need for more.

While we can use people with printing or magazine experience, the biggest demand is for editors. We need two or three more, at least, if we are going to continue to grow and put out more books and magazines. We are looking for hams with as much experience in hamming as possible . . . hopefully with good technical backgrounds . . . who are into working more than clock-watching.

We have a dozen books in the works for release soon and we would like to increase this to a hundred . . . if only we had the hams to help get them ready for printing. We'll need help with getting a new CB magazine started . . . and with a new hobby computer magazine. We need a lot more help in getting *73* out each month. We need help in marketing the books, magazines and tapes . . . through direct mail, dealers, newsstands, reps, etc. The more readers we get, the more people will be able to enjoy the magazine every month.

If you have the background, a bunch of enthusiasm, are a self-starter and don't have to be told what to do . . . if you like working in a very unusual and relaxed atmosphere, . . . if you are work-oriented . . . if you would like to live in a beautiful part of the country . . . you can do worse than let us know about it.

A GOOD BOOK

A good book indeed is the *Handbook for Electronic Engineering Technicians*, for $19.50. The price is high, but this is an excellent book and well worth the investment. The material is a bit brief for the book to be used strictly as a study guide, but as a handbook . . . as a reminder of how just about everything you'll run into in electronics works, it is superb. The math is kept to an absolute minimum and every subject is covered concisely. McGraw-Hill. If you are at all serious about understanding electronics, you just can't do without this new book.

A TTL Tester

--great for unmarked bargain ICs

Being economically minded by necessity, I have often purchased unmarked, untested semiconductors at really bargain prices. This practice has necessitated the construction of special test equipment.

One such piece of test equipment was designed to test TTLs. This TTL tester is an expanded version of a very simple diode tester. The simplicity of this diode tester should not be allowed to downgrade its usefulness. See Fig. 1.

Using this diode tester, the breakdown or zener voltage of a diode or transistor can be quickly determined. Transistors can be classified, after some experience in using this simple tester, into small or large signal, low or high voltage, oscillators, amplifiers, switching, high or low leakage, etc. It also indicates an open or short which makes it useful for a continuity tester.

A built-in calibration source can be added with the addition of one or more zener diodes and switches. See Fig. 2.

The TTL tester is this same basic diode tester with a few more components and a 5 V source (Fig. 3). Any 5 V dc power supply can be used but should be protected from overload by a fuse or current limited output because of a TTL short or human error. Phone tip jacks are used for test points, with external test connections being made by jumper wires with phone tips. See Fig. 4.

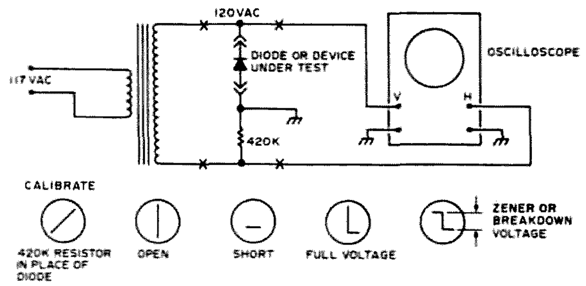

Fig. 1.

Operation

For an unknown TTL, place the TTL into the test socket and turn power on. The vertical probe is inserted into the CAL TP and the scope adjusted as in Fig. 5a. Use an educated guess or flip a coin to choose a TP that would ordinarily be ground, such as TP4 or TP7. Say, for example, that we choose TP7.

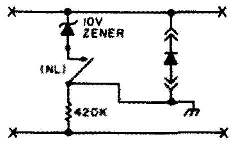

Fig. 2.

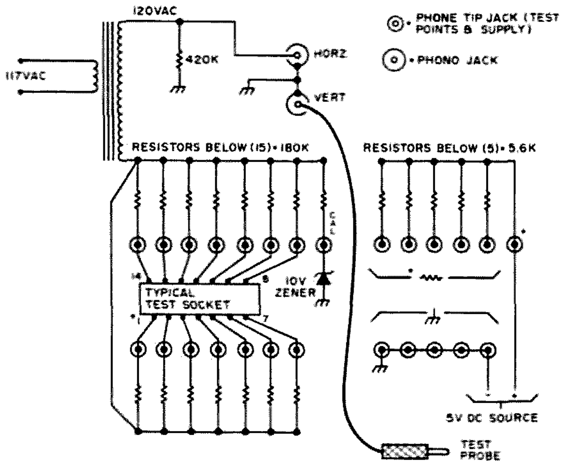

Fig. 3.

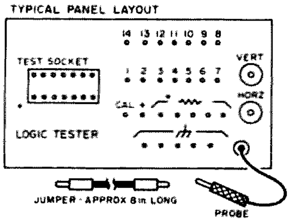

Fig. 4.

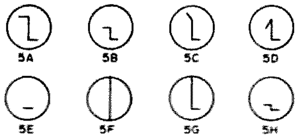

Fig. 5.

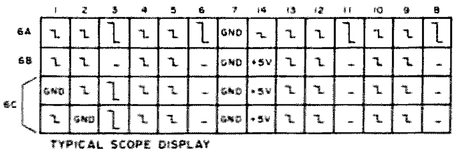

Fig. 6.

A jumper would then be placed from a ground TP to TP7. The vertical probe is then moved to each TP, TP1 through TP14. The display on the scope (Fig. 6a) may be similar to any figure of Fig. 5, but we are looking for one that is decidedly different, or the oddball. Say in our example we have only one that looks like Fig. 5h on TP14. It would appear that we have made a wise choice of TP7 for our ground because + and - are usually on 14 and 7 as one combination for TTLs. Reasonably sure that TP7 is our ground, we once again take the vertical probe through TP1 to TP14 with a ground on TP7. A record (mental if you like) can be made of each TP test as in Fig. 6. Connect +5 V to TP14 with a jumper. This will operate all gates, etc. Check each test point again with the vertical probe. A change of state will be noted as in Fig. 6b. In our example, a change of state occurred at test points 3, 6, 11 and 8 for a total of four changes; thus we may have a quad device. Next we monitor the points of change using the vertical probe. The first in this example is TP3.

A single jumper lead from ground is moved to each test point of no change. In our example, the ground jumper lead of TP1 changes the state of TP3. See Fig. 6c. Removing the lead from TP1 restores the state of TP3. Placing the jumper of TP2 changes the state of TP3, etc. (Fig. 6c). Moving on to TP4, 5, 13, 12, 10, 9, we note no change on TP3. In our example, we find the same relationship between TP4, 5, 6 and TP13, 12, 11 and TP10, 9, 8. The example was a 7400 TTL (Fig. 7) which is a quad 2 input NAND gate TTL. A study of several known TTLs will give you the experience necessary to use this simple tester. The number and type of jumpers will of course depend upon the TTL under test. The 7451 TTL for instance requires two jumpers.

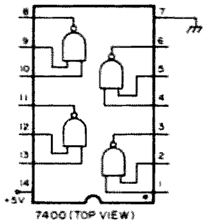

Fig. 7.

In the end we will know what the circuit is and its maximum breakdown voltage (Figs. 5b, c, d, g) as well as whether it is an open collector (Fig. 5d) or if the circuit is open or shorted (Figs. 5e, h) and most importantly, whether it is working properly. ■

How to Check Memory Boards

-- use this simple program

While the computer hobbyist faces many trials and tribulations during his quest to get his fabulous (and complex) new toy "up and running," one of the most frustrating problems that he can encounter involves debugging a troublesome memory board. This article describes a simple memory diagnostic program, and illustrates its use in tracking down problems in memory. While not a "cure-all" for all memory related problems, especially those that render the complete board inoperable, it will allow the hobbyist to "exorcise" those gremlins responsible for such irritations as memory locations which refuse to store the exact data which you load into them, and addresses which appear to change their contents as though they had a mind of their own.

The two problems which are presented for illustrative purposes are real-life "bugs" which cropped up following the recent assembly of two 4K memory boards. Note that the program and associated debugging technique which evolved were developed for an Altair 8800 (but should be applicable, with appropriate modifications, to other systems).

At this point, a few words concerning the memory diagnostic program (Table 1) are in order. (Ignore those parts of the program in parentheses, for the time being.) The program, as presented, resides on page 2, address 000-041 (octal). This address was chosen because I already had a simple "MONITOR" residing on pages 0 and 1, and I was certain that page 2 had no "bugs," due to the fact that other small programs which resided there from time to time performed their appointed duties without difficulty. The program can be placed on any other page (change memory references accordingly), assuming that you are certain that the chosen page has no "bugs" which would interfere with the program's operation. Needless to say, the program can be placed on a correctly operating board, and used to debug all 4K of other appropriately addressed boards. The only restriction concerning placement of the program is that the page(s) to be tested must be different from that page on which the program resides ... hence, my choice of page 2.

The program also assumes that you have an octal conversion and print subroutine ("OCTOUT") which it can call. Since this is generally a part of most monitors, it is not included here.

Operation of the program is straightforward. The program loads the value of an address, as data, into that address. For example, address 000 contains data 000, address 001 contains 001, etc. Then the computer compares the contents of the address with the numerical value of the address; if they differ, the program will print out the address and its incorrect contents. Since this method is not infallible, those parts of the program in parentheses are utilized to load and compare specific patterns of data in memory, if necessary. To employ this modification, simply substitute the parts of the program in parentheses for the existing parts. The

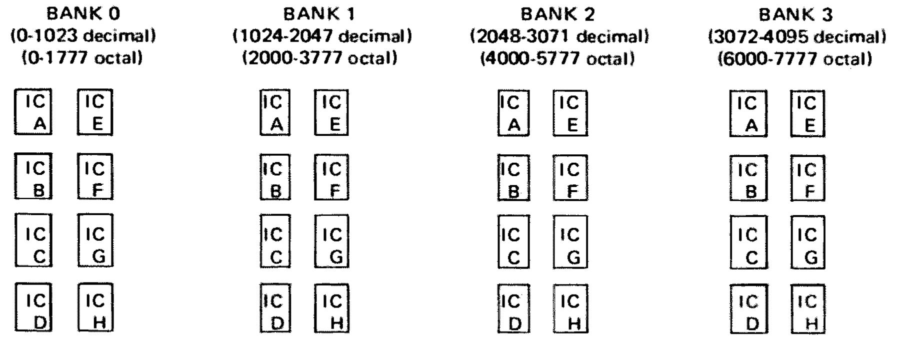

Fig. 1. 4K memory segment of 2102s.

need for the modified program will be made clear in due course.

Table 1. Memory diagnostic program.

Some Basics

Before proceeding further, a general discussion of a 4K memory board is in order. These boards usually employ 2102s or a reasonable facsimile thereof, and have the chips arranged in 4 banks of 8 chips each (see Fig. 1). The particular bank chosen is a function of a two-to-four decoder, which decodes address lines 10 and 11. Fig. 2 is a schematic and truth table of a typical circuit.

The active output of the decoder circuit pulls down the eight pin 13s of the particular bank of 2102s being addressed, thus enabling that particular bank.

Table 2 illustrates the address decoding with regard to each bank and the associated 256 word pages therein. The particular page in a bank is a function of the state of address lines A8 and A9. Remember, to activate a given page or address, the appropriate address pins on the chip are pulled down.

Each chip within a bank corresponds to a particular bit, 0-7.

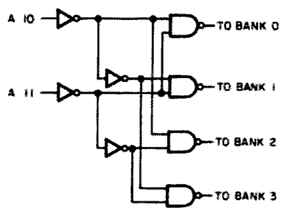
Case 1

Symptoms ... program data loaded into pages 6 and 7 was full of errors when dumped. Testing of pages 6 and 7 with the unmodified program produced the results illustrated in Table 3. Since errors resided in pages 6 and 7, we can localize the difficulty to bank 1 (refer to Table 2). Notice that the contents of the addresses which contain errors are augmented by 004. This points to a problem with bit 2 (chip C) in block 1. The fact that the problem showed up only on pages 6 and 7 seems to indicate that whenever address bit A9 was active, chip C on bank 1 contained a 1 ... producing the 004. Perhaps an internal short in that chip. Substitution of the identified chip corrected the problem.

Case 2

Symptoms ... interaction between pages 4 and 5; specifically, data entered into page 4 changed some ... only some ... data in page 5. Initial use of the memory diagnostic program as in case 1 indicated no errors, although it was known that the pages were interacting. At this point, pages 4, 5, 6 and 7 were loaded with 000 using the modified memory diagnostic. An octal dump of these pages indicated that all were zeroed. The next step consisted of loading the pattern of 144 into page 4. The memory diagnostic and octal dump confirmed that page 4 contained all 144s. However, an octal dump of page 5 revealed that, although it had not been reloaded, it now contained 040s (i.e., bit 5 was always set). Since it is page 5, our problem resides in bank 1 (refer to Table 2), and because it is 040, the problem is associated with chip F in bank 1 (see Fig. 3). Now, since the error popped up on page 5 although page 4 was the one being addressed, it

Fig. 2. Typical decoder circuit (and truth table) for decoding address lines A10 and A11 to choose the appropriate bank of 2102s.



Address Lines –	A11	A10	A9	A8	A7	A6	A5	A4	A3	A2	A1	A0
Decimal Weight –	2048	1024	512	256	128	64	32	16	8	4	2	1

	A11	A10		
Bank 0	0	0	–	0 – 1023_{10} – pages 0-3_8
Bank 1	0	1	–	1024 – 2047_{10} – pages 4-7_8
Bank 2	1	0	–	2048 – 3071_{10} – pages 10-13_8
Bank 3	1	1	–	3072 – 4095_{10} – pages 14-17_8

Table 2. Address decoding with regard to bank and page selection.

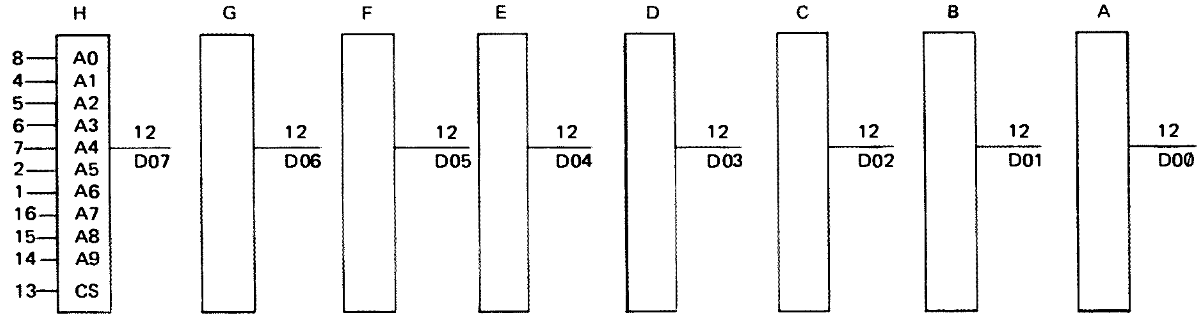


Fig. 3. The logic state of each 2102 in the bank of 8 contributes to the value of the data word at a given address. Note that each 2102 corresponds to one bit in an 8 bit word.

would suggest that A8 on chip F in bank 1 was going low (remember A8 and A9 determine the particular page in a bank that is being addressed). Manual addressing

000	004	010	014
001	005	011	015
002	006	012	016
003	007	013	017

Table 3. Typical readout from "DEBUG," illustrating address and errors (partial) of Case 1.

of page 4 from the display/control board and activation of the examine switch, indeed, showed that A8 on chip F in bank 1 was low. The corresponding pins of other chips in this bank were high. It turned out to be a case of the pin not making contact in the socket. Removal of the chip revealed that pin A8 had been bent underneath upon insertion. Straightening the pin and reinserting the chip (with care) corrected the problem.

Conclusion

The above procedure is relatively straightforward and best of all does not require any sophisticated equipment. In fact, you already possess the two most important pieces – the computer itself and "ham ingenuity."

The program also is relatively simple as memory diagnostic programs go. I would recommend that a number of patterns be tried with the modified program to ensure that all possible bits and consequently all possible chips in a bank be tested. Embellishments such as these could be built into the program by the software connoisseurs among us. Space doesn't permit elaborating upon other possible sources of memory problems. However, the technique of isolating the bank, the chip, and the appropriate pins has been presented and, hopefully, will be of value when a memory problem occurs. Happy troubleshooting. ■

I/O REPORT

from page 95

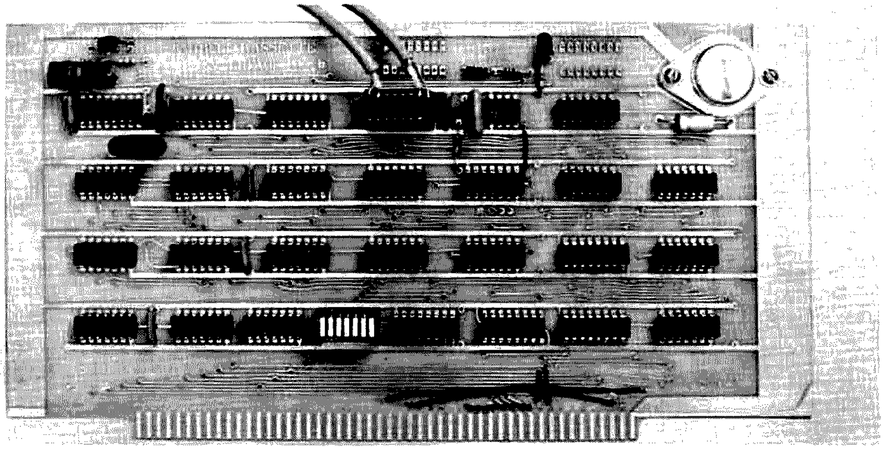
bi-phase data signal, which is then applied directly to the recorder input. The high reliability of this technique stems from the fact the data and clock are recorded together and recovered together. Therefore, speed variations in an inexpensive recorder are essentially ignored.

The dip switches mounted at the bottom center of the board (see photo) are set up for the device select code ("device address"). The audio cables to the recorder are soldered to the board via the dip plug located in the top center of the board. There are two empty sockets provided for expansion and/or modification. The LED located at the top of the board is used for adjusting the read level (in conjunction with the volume control on the recorder) and eliminates the need for an oscilloscope for initial adjustments.

It's always a pleasure to plug something into a system and have it work the first time. That is exactly what happened when we plugged the Tarbell unit into our Altair. The only "problem" we encountered was toggling the read and write routines into the Altair by hand (since a terminal wasn't connected at the time) using the HEX listings provided in the manual. (Toggling hexadecimal into an octal front panel does require a few mental adjustments on the part of the toggler!)

Don Tarbell, the owner of Tarbell Electronics, is one of the pioneers in this hobby, inasmuch as he designed and built his home system from scratch back in 1972. (He also developed a BASIC interpreter, assembler, text editor, operating system, and some sophisticated artificial intelligence software for the system.) He is one of the founders of the Southern California Computer Society, and is currently serving on the board of directors. In other words, it would appear that Tarbell Electronics is in tune with the hobby community and its needs. (Incidentally, his next offering for the Altair community will be a Universal I/O and ROM board.)

Contact: Tarbell Electronics, 144 Miraleste Drive #106, Miraleste CA 90732. Phone: (213)-832-0182. $120 for complete kit or $175 assembled and checked out. The 22-page manual is available at $4, which is deductible from your order. Suggestion: Go ahead and order the Processor Technology software package at the same time you order the cassette – it's worth it!



The Tarbell Cassette Interface.

The New Ham Programmer

-- making those confounded uPs work

Can today's amateur radio operators program one of the microprocessor systems that are so much in vogue? Are these microprocessor systems worth anything to today's amateur? This article is about computer programming. There are a number of fundamental concepts involved in programming today's computers; these fundamental concepts apply to the under-fifty-dollar microprocessor, to an IBM 370 and to just about everything in between. The concepts behind programming a computer are really very simple, and the amateur radio operator is already familiar with the basic ideas. In order to clarify the concepts and relate them to ideas with which we are familiar, this article will go through an exercise examining a typical ham radio contest summary sheet, with the goal of finally writing a computer program which will calculate the contestant's score.

In the 1st Annual Hypothetical Contest, your score is determined by multiplying your total number of QSOs by one (1) if your power input is greater than 100 Watts, or by two (2) if your power input is less than or equal to 100 Watts.

For this contest, the summary sheet shown in Table 1 has been provided to simplify the contestant's scoring.

This summary sheet illustrates some of the important concepts of computer programming. Though not really a concept, the first observation which must be made is that the summary sheet is easy to follow, simple-minded and somewhat tedious.

A computer operates under the control of a *stored program;* in this example, the summary sheet presented is analogous to the stored program which controls the computer. The *CPU* (Central Processing Unit) interprets the program instructions just as our hypothetical contestant reads and interprets the instructions on the summary sheet. In a computer, both the program and data are stored in a memory; the summary sheet is the memory upon which the printer has stored the program, and the contestant stores his data within the boxes provided. The contest summary sheet analogy illustrates one more important concept upon which the usefulness of modern computers is built: *transfer of control* based upon a logical operation (as illustrated in line 2 of the summary sheet). On this line, the contestant's power input (a previous calculation) is compared with 100 Watts, the contest rule for determining the QSO multiplier. Based on this comparison, the contestant is directed to go to either line 5 or, by implication, to continue to the next sequential line. As a general rule, the organization of CPUs is such that the program is executed one step at a time, sequentially, in the order in which the instructions appear, until a transfer of control operation is encountered (the "go to" on line 2), which changes the order in which the instructions are executed.

Flow Charts

A flow chart is a graphical method of describing a process. The process we are concerned with is programming a computer, and a flow chart can be used as an aid in the design and documentation of computer programs. There are a number of standard flow charting symbols which are universally understood in the computer programming community. Since this article is not meant to be a course in flow charting, I will introduce just two flow charting symbols (Fig. 1) and present a flow chart (Fig. 2) which describes the process of calculating the score for the Annual Hypothetical Contest.

The flow chart in Fig. 2 is one of many possible representations of the summary sheet process. In this chart we see the introduction of the idea that the variables in the calculation can be given names: POWER, PLATE.VOLTS, PLATE.CURRENT, SCORE and QSOs. The names chosen have some meaning to the reader who has followed through the contest scoring example. Quite a few details have intentionally been left out of the flow chart; the flow chart is designed to give an overall idea of what is to be accomplished. It is worthwhile to note at this point that we could just as well have started with the flow chart and evolved the summary sheet as an implementation of the process described by the flow chart. With reference to our summary sheet, the value PLATE.CURRENT is entered in the box on line b, the value of SCORE is entered in the box on line 10, etc. On the summary sheet, the instruction on line 2 is the implementation of the decision block in the flow chart.

Before we can consider how the Hypothetical Contest summary sheet calculations can be done with a program in a computer, we must take a few minutes to describe the computer itself. For this discussion, the INTEL 8080 will be our CPU. The INTEL 8080 is probably the most popular of the 8-bit microprocessors; however, the programming ideas presented here apply generally.

The INTEL 8080 is a very simple device; it can add, subtract, make logical comparisons and transfer control. The 8080 has seven 8-bit *registers*, a 16-bit *stack*

1. Calculate your final input POWER (see lines a-c)

2. If your POWER is less than or equal to 100 go to line 5

3. Take the number of QSOs (line 9) and put this number in SCORE (line 10)

4. STOP

5. Take the number of QSOs (line 9)

6. Multiply the number of QSOs by two

7. Enter the product in SCORE (line 10)

8. STOP

9. Number of QSOs

10. SCORE

Power Calculation:

a. Multiply the PLATE CURRENT (entered in line b) by the PLATE VOLTAGE (entered in line c), return to the next line in the Summary Sheet

b. PLATE CURRENT

c. PLATE VOLTAGE

Table 1. First Annual Hypothetical Contest summary sheet.

pointer and a 16-bit *program counter.* The stack pointer, though very important to making full use of the power of the 8080, will not be discussed here. The program counter is quite simply a pointer to the instruction to be executed. Relating to the summary sheet example, the program counter may be thought of as your index finger pointing to each line of the instructions as you read the line. Before our program is started, the program counter register must be initialized to point to the first instruction in the program; from then on, the program counter will automatically go through each instruction of the program as it is executed.

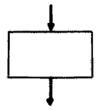
The seven 8-bit registers are named A, B, C, D, E, H and L. The A register is also called the *accumulator* and is used in the arithmetic operations such as addition and subtraction; typically, numbers in other registers are added to or subtracted from what is in the accumulator with the result being left in the accumulator. The other registers have various uses; in our program we will use only the B and C registers. All of the registers may be used to save results of computations. Since most computations change the A register, it is convenient to be able to save results in other registers which may be referred to in subsequent steps of the program; in our program, we will use the C register to save the result of the POWER calculation.

An instruction for the 8080 is made up of an operation code *(OP code)* and an *operand.* For example, an addition instruction would be coded for the 8080 as ADD C. The OP code is ADD and the operand is C. From INTEL's documentation we find that the instruction ADD C adds the contents of the C register to the contents of the accumulator and leaves the result in the accumulator. Generally, the operand can be either a register or a storage location; the instruction, LDA 0400, *loads* the contents of storage location 0400 into the accumulator.

The 8080 program used to compute contest scores is shown in Table 2. The left-hand column is the address (in hexadecimal) where each instruction or variable is stored in the computer's memory. The second column from the left shows the contents of each memory location in hexadecimal. In the case of instructions, the content of the memory location is the operation code which the CPU decodes to determine what instruction is to be executed. You may notice that the memory addresses in the left-hand column seem to increment in some random manner. The reason for this strange progression of address locations is that instructions for the 8080 occupy from one to three storage locations. The very first instruction in the MAIN PROGRAM starts at memory location 0100. This instruction is a CALL instruction which transfers control to a *subroutine;* the operation code for this instruction is "CD" and the starting address of the subroutine is location 0250. A pair of hexadecimal digits occupy one storage location, so the operation code "CD" occupies location 0100 and the address 0250 occupies locations 0101 and 0102.[1] The next instruction, MOV C,A, will therefore start in the next available location, namely 0103.

The third column from the left lists the computer instruction in a more readable way than the hexadecimal notation in the second column. MOV is a move instruction, LDA is load the accumulator, STA is store the accumulator, etc. In truth, this program was written as seen in column three and subsequently translated into the machine instruction codes shown in column two.

The fourth column contains comments about the program and indicates the use



Process Block — *This block describes a process or operation such ad addition, multiplication or the like. The process flow is thought of as entering the top of the block and leaving the bottom.*

Decision Block — *This block describes a decision (such as "is something greater than something else") which is made in the process. The process flow is thought of as entering the top of the block; a decision is made within the block which determines from which of the output legs the process will continue.*

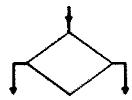


Fig. 1.

[1] The architecture of the 8080 requires the low order address of the operand in the location immediately following the OP code, and the high order address in the second location following the OP code. Here, location 0101 will contain 50 and location 0102 will contain 02.

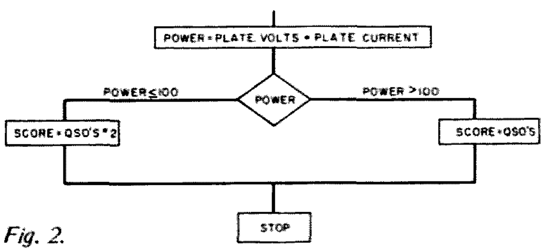

Fig. 2.

MAIN PROGRAM:

0100	CD 0250	CALL 0250	CALL SUBROUTINE TO CALCULATE POWER
0103	4F	MOV C,A	MOVE POWER FROM A REG TO C REG
0104	3A 0207	LDA 0207	GET THE VALUE 100 (THE VALUE 100 IS STORED IN LOCATION 0207)
0107	91	SUB C	100 (IN REG A) – POWER (IN REG C)
0108	FA 0113	JM 0113	JUMP ON MINUS TO 0113 JUMP IF POWER GREATER THAN 100
010B	3A 0209	LDA 0209	GET #QSOs IN REG A FROM LOCATION 0209
010E	87	ADD A	MULTIPLY BY 2 BY ADDING THE #QSOs IN REG A TO ITSELF
010F	32 0208	STA 0208	STORE RESULT IN 0208 WHICH HAS BEEN ALLOCATED TO SAVE THE SCORE
0112	76	HALT	
0113	3A 0209	LDA 0209	GET #QSOs IN REG A FROM LOCATION 0209
0116	32 0208	STA 0208	STORE IN LOCATION 0208 WHICH HAS BEEN SET ASIDE TO SAVE THE SCORE
0119	76	HALT	

DATA AREA:

0201	00		CURRENT (TO BE FILLED IN WITH CONTESTANT'S PLATE CURRENT)
0202	00		VOLTAGE (TO BE FILLED IN WITH CONTESTANT'S PLATE VOLTAGE)
0207	64		100 DECIMAL
0208	00		SCORE CALCULATED BY PROGRAM
0209	00		#QSOs (TO BE FILLED IN WITH CONTESTANT'S NUMBER OF QSOs)

POWER SUBROUTINE:

0250	3A 0201	LDA 0201	GET CURRENT
0253	4F	MOV C,A	PUT CURRENT IN REG C
0254	3A 0202	LDA 0202	GET VOLTAGE
0257	47	MOV B,A	PUT VOLTAGE IN REG B
0258	3A 0201	LDA 0201	GET CURRENT
025B	05	DCR B	DECREMENT REG B (REG B STARTED OUT WITH THE VOLTAGE WHICH WILL BE THE NUMBER OF TIMES CURRENT WILL BE ADDED TO ITSELF TO FORM THE PRODUCT CURRENT*VOLTAGE)
025C	C8	RZ	RETURN IF ZERO . . . DONE
025D	81	ADD C	ADD THE CURRENT IN REG C TO THE SUM BEING ACCUMULATED IN REG A
025E	C3 025B	JMP 025B	GO TO LOCATION 025B

NOTE: THE PRODUCT CURRENT * VOLTAGE IS FORMED BY ADDING CURRENT TO ITSELF VOLTAGE TIMES. FOR EXAMPLE, IF THE VOLTAGE IS 5 AND THE CURRENT IS 3, THE PRODUCT CURRENT * VOLTAGE = 3+3+3+3+3 = 15

NOTE: THE RESULT IS RETURNED TO THE MAIN PROGRAM IN THE A REGISTER

Table 2.

of storage locations in the data area of the program (locations 0200 – 0209).

NOTE: The values used in this program are *decimal*. In reality, the values stored in memory would be in hexadecimal or octal. A conversion routine and an output routine would be necessary if it were desired to output these numbers in decimal to a TTY or TVT. Therefore, the decimal values are used for simplicity.

The computer program is just about as straightforward as possible, but it is worth the time to go through each instruction examining what each does and why it is there.

The first instruction in the *main program* is a call to a subroutine. A subroutine is simply another part of the total program which does some function; in this case, the subroutine calculates the power of the contestant and saves the result in the accumulator (A register) of the computer. The call instruction essentially transfers the execution of the program to a specified location in the computer memory; in this program, the subroutine to calculate power is at memory location 0250. When we get into the discussion of the power subroutine we can consider the calculations in more detail; at this point it is sufficient to note that the CALL 0250 will do the desired calculation and continue on to the next instruction. The idea behind the notion of subroutines is similar to the first instruction on the summary sheet. The precise instructions for calculating power are not part of the summary sheet; rather, these instructions are set apart in lines a-c just as the instructions for calculating power in the computer program are set aside at memory locations 0250 through 0260.

Having calculated the contestant's power, the next thing which must be done is to check whether the con-

testant's power is greater than one hundred Watts in order to determine the multiplier; the three instructions starting at location 0103 do just this. First, the power calculated by the subroutine is moved to register C for safekeeping (MOV C,A); then the accumulator is loaded from storage location 0207. Since location 0207 was set up to contain the number 100 decimal (64 in hexadecimal), the accumulator now has 100 in it; SUB C subtracts the contents of the C register from the contents of the accumulator. Recalling that register C contains the contestant's power, the accumulator, after the SUB C instruction, contains 100-POWER. Notice that if the power is greater than 100 Watts, the above calculation will result in a minus number. The instruction JM 0115 at location 0108 completes the test on the contestant's power; this Jump-on-minus instruction (JM) will jump (transfer control) to location 0115 if the previous subtraction resulted in a minus number. The Jump-on-minus instruction is an implementation of the transfer of control from the decision block in our flow chart; just as the decision block had two different exit paths depending upon the results of the decision, the JM instruction controls the flow of the program: either to the next sequential location (010B) if not minus, or to location 0115 if minus.

If the contestant's power was less than or equal to 100, the next instruction executed is the LDA 0209 at location 010B. This instruction loads the accumulator with the contents of location 0209. Location 0209 is set aside to hold the number of QSOs, so the accumulator will be loaded with the number of QSOs that our contestant had during the contest. Since we are now considering the case where the final score is determined by doubling the QSO count, we can accomplish the desired doubling by simply adding the accumulator (number of QSOs) to itself; ADD A adds the contents of the accumulator to the contents of the accumulator, effectively multiplying the contents of the accumulator by two. Finally, the contestant's score is saved in memory location 0208 which has been set aside to save the SCORE; STA 0208 stores the contents of the accumulator in storage location 0208.

Statement Number	Command (Instruction)	Comment
10	INPUT P	Input power (P) value from TTY or TVT
20	INPUT Q	Input number of QSOs (Q) from TTY or TVT
30	IF P = >100 GOTO 50	Decision statement regarding power (100 Watts or greater?)
40	PRINT "SCORE= " Q	If the value for Q (#of QSOs) were 1,632 (decimal, mind you), the printout on the TTY or TVT would be: SCORE = 1,632
45	GOTO 99	Go to end of program
50	Let S = 2 * Q	Calculate score (S) if power less than 100 Watts (2 times Q)
60	PRINT "SCORE=" S	Printout of score (same as in statement number 40)
99	END	End of program

Table 3.

Remember the JM instruction at 0108? This instruction transferred control to location 0115 if the power was greater than 100. Now we must consider what must be coded for the computer to execute at location 0115. In this case, the power was greater than 100; all we want to do is take the number of QSOs as the SCORE. LDA 0209 loads the accumulator from the location set aside for the contestant's QSO total, and STA 0208 stores the contents of the accumulator in the storage location set aside for the SCORE.

The calculation of the contestant's power is done by the subroutine at storage location 0250. The INTEL microprocessor does not have a multiply instruction, so another approach must be taken by the programmer who wants to perform the calculation, POWER = CURRENT*VOLTAGE. Multiplication may be thought of as the summation of the multiplicand, with the multiplier specifying the number of times it is to be summed. For example, to multiply 10 by 6 we can add 10 together 6 times: 10*6 = 10 + 10 + 10 + 10 + 10 + 10 = 60. We shall use this approach to multiply current by voltage to get the power. Register B will be loaded with the value of the voltage, and every time we add the current to the sum being accumulated in register A, we shall also decrement register B. When register B becomes zero, we have added the current together voltage times.

Rather than going through each instruction as we did in the main program, let us look at the new instructions introduced in the subroutine code. MOV B,A moves the contents of the A register into the B register; since the A register had just been loaded with the voltage, MOV B,A moves the voltage into the B register. As mentioned above, the B register will be decremented each time the current is added to the A register; DCR B does just this.

The return instruction, RZ at location 025C, transfers control to the storage location immediately following the CALL instruction in the main program when register B is decremented to zero. Special hardware in the CPU keeps track of where the CALL instruction was executed so that the return instruction can return to the instruction which follows the call. With this call and return facility, it is possible to call the power calculation subroutine from any other program which may want to make such a calculation. Admittedly, this subroutine is not very sophisticated, but envision the possibility of writing more sophisticated subroutines which calculate logarithms, trigonometric functions, etc. Once such subroutines have been written once, other programs can take advantage of them by simply calling them. Many higher level languages such as FORTRAN are implemented with a library of subroutines; a FORTRAN statement such as A = SQRT(47.667) is executed by calling a subroutine which calculates the square root of the arbitrary value 47.667.

By now you are surely convinced that computer programmers must be a weird bunch to put up with such a dumb animal as the computer. The program so laboriously presented will make the calculations required for the contest scoring problem, but it has some severe restrictions. To point out just one of these, notice that one

storage location has been allocated to save the contestant's score. One storage location is 8 bits in length; this allows our contestant to accumulate a total score of only 255. This is, of course, a limitation, but not one which can't be overcome. It involves having another subroutine which will receive the value and convert it into a fixed or floating point value occupying more than just a single storage location. A better way to get around all of these problems is the use of a *higher level language*. Several references have been made to FORTRAN (which is a higher level language), but let's take a look at how BASIC can solve some of the above problems. BASIC can also very easily take care of some of the problems mentioned earlier, such as hex-to-decimal, or octal-to-decimal conversion, and input and output routines. For example, the BASIC program in Table 3 will perform the same functions as our earlier program, and also take care of the "problems."

It's quite evident from this program that BASIC is an easy language to use, and did a very satisfactory job of solving the task (and in very few statements). The disadvantage (if you want to call it that) is that we are now somewhat removed from the machine. The previous machine language program required that we get to know the machine, its operation, and architecture in order to program it. This can certainly be more challenging at times and also allow you to do some things you can't with a higher level language such as BASIC.

Yes, today's ham radio operator can program a microprocessor. The real challenge lies in finding applications which are well suited to the microprocessor's capabilities. ■

The Soft Art of Programming

-- getting started with BASIC

Here are some interesting and worthwhile ideas for the beginning programmer, and some reminders (or review) for the experienced. – Ed.

Okay. So my microcomputer kit finally showed up in the mail, and I put it together. I watched the panel lights blink for a few days, then I had some friends over to look at it. They looked at me with sort of a funny smile and said, "But what are you going to *do* with it?" I grabbed for a copy of *73* and riffled through it searching frantically for Wayne's editorial, mumbling, "You know, anything you, uh . . .", but they were already out the door, smiling and saying they had to get back because "Mary Hartman, Mary Hartman" was going to be on in a few hours.

I knew it wasn't my breath, and I was wearing a clean shirt. There was no way around it; I was going to have to learn how to program.

Actually, programming a computer can be tremendous fun. Also tremendously rewarding and, let's face it, tremendously frustrating if you go about it wrong. In this article, I'm going to give some tips about learning to program, in the hopes of keeping you on the fun side instead of the hair pulling side. I'm not going to try to teach you to program – that would take a whole book. No, I'm going to give you some things to try, suggest a few books that will be useful, outline some important ideas to keep in mind, and give some examples of how to write programs. You'll get the most out of this if you read it again every so often as you get farther and farther into programming. Don't take anything I say as gospel – try to prove me wrong! Above all, have a good time.

Programming is like planning a task. The idea is to figure out how to express some overall action that you want the computer to do in terms of elementary building blocks, just as circuit design consists of putting together simple components to do a complex overall process. All the examples here assume that the building blocks are the legal statements and forms of BASIC, but the *ideas* apply to any computer language, including machine language.

Let's assume that you have enough hardware to run 8K Altair BASIC or the equivalent, and that you've been able to decipher the manuals well enough to get the BASIC system loaded into your machine. The first thing to do is learn what the basic building blocks are, and to start seeing how they can be fit together.

Phase I: Building Blocks

The key to learning to program is to keep having fun. Keep tinkering! Start with a one or two line programs, say

```
100 PRINT "GREETINGS!"
200 END
RUN
```

(Remember to hit the "RETURN" key at the end of each line.)

Keep RUNning it and adding in new statements to see what happens.

Variable	Type	Use
M$	string	name of magazine
I	numeric	number of issues per month
Y	numeric	length of subscription in years
C	numeric	cost of subscription
P	numeric	per issue cost
A$	string	answer to "any more" question.

Table 1.

```
100 PRINT "GREETINGS!";
150 PRINT A
200 END
RUN
```

(Look in your manual to find legal statements and to find what keys to hit to wipe out mistakes.)

Every time you find something that works, keep playing around with it.

```
100 PRINT "GREETINGS!";
120 LET A=1
150 PRINT A
200 END
```

Loops are very important ways to get a short program to do a lot of work. Start writing some infinite loops like the one below and watch what happens. Of course, you'd better find out how to stop one "by hand" (in Altair BASIC and many others, holding down the "CONTROL" key and a "C" together will stop your program).

```
100 PRINT "GREETINGS!";
120 LET A=1
140 LET A=A+1
150     PRINT A
170     REM: GO BACK
171     REM: FOREVER
180     GO TO 140
200 END
```

(Notice how indenting the statements in the loop makes them stand out.)

Write programs that fill up your screen or printout with crazy, wild patterns:

```
10 PRINT "GARBAGE";
20 GO TO 10
30 END
```

Fairly soon you'll get a feeling for how the basic units work and you'll want to have more control over what your programs do and write bigger programs that do definite tasks. A good book will help a lot.

Phase II: Book Learning

Books written specifically for home computer users will be coming out soon — in the meantime, here are some that seem pretty good.

My Computer Likes Me (When I Speak in BASIC) by the crew at the People's Computer Company (also available from *73*): a nice, mellow, friendly, encouraging but very brief introduction. If you're starting completely from scratch, begin here, then move on to a book that covers more material.

BASIC by Samuel L. Marateck, Academic Press, 1975: moves at a very patient pace, and has lots of examples. Unfortunately, a lot of the early examples are obviously just made up on the spur of the moment and don't demonstrate how to use the statements in the context of meaningful problems. Recommended if you find that one of the other books goes too fast for you.

BASIC by Michel Boillet and Lister Horn, West Publ. Co., 1976: moves a little faster, has nice question and answer sections, and has loads of good problems at the end of each chapter. Many of the problems and examples are business oriented (accounting, interest payments, etc.), so if that's one of your interests, this may be the book for you.

Computers: Their Impact and Use: Basic Languages by Robert Lynch and John Rice, Holt, Rinehart, and Winston, 1975: The first half has a broad overview of computing — history, applications, future projections. The second half covers programming in BASIC, moves fairly rapidly, and includes quite a few nice, real world examples.

BASIC Programming by John Kemeny and Thomas Kurtz, John Wiley, 1971: the "old standard" (Kemeny and Kurtz invented BASIC). The book moves quickly and may be hard to follow if your high school math is too rusty, but it has lots of really clever examples. If you can get through it, you'll get a lot out of it.

More are coming out all the time, so keep your eyes open for one that suits your needs.

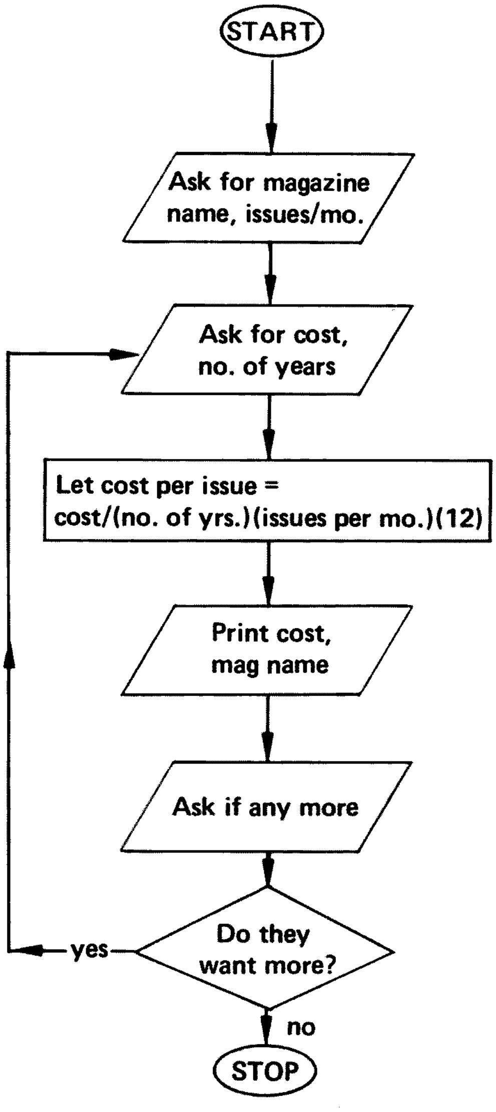

Fig. 1.

In using these books, there are three main problems. First, all except *My Computer Likes Me* are written for classroom use. This means that they have a fairly formal style (you have to get *teachers* to like it if you want to sell a textbook), and that they go fairly fast (they assume your teacher will explain what's going on sometimes). If you take your time, try everything out on your home system as you go, and ask a friend for help when you get really stuck, you'll be able to get loads of useful, fun ideas from any of them. Well worth the effort.

Second, since there are no agreed upon standards for BASIC (they're coming soon, thank grid!), you'll find that you have to translate some of the little details before programs in the book work on your system. Your manual will tell you what symbol to type to wipe out the last character, whether to type "NEW" or "SCR" or whatever to start entering a new program, etc. Usually you'll find that your system allows some statements and commands the book doesn't and vice versa. Fortunately,

```
10 REM:PROGRAM TO COMPARE VARIOUS SUBSCRIPTION
11 REM: DEALS.
20 REM:GET MAGAZINE NAME, PUBLICATION RATE.
30 PRINT "WHAT'S THE MAG";
40 INPUT M$
50 PRINT "HOW MANY ISSUES PER MONTH";
60 INPUT I
70 REM:NOW GET DETAILS OF SUBSCRIPTION DEAL.
80 PRINT "HOW MANY YEARS IS SUBSCRIPTION FOR";
90     INPUT Y
100    PRINT "AND HOW MUCH IS IT (IN DOLLARS)";
110    INPUT C
120    REM:COMPUTE PER ISSUE COST (#ISSUES=I*Y*12)
130    LET P=C/(I*Y*12)
140    REM:OUTPUT THE COST PER ISSUE
150    PRINT " "
160    PRINT "THAT'S $"; P; "PER JUICY, FUN-PACKED ISSUE
                                              OF ";M$
170    PRINT " "
180    PRINT " "
190    REM:MORE?
200    PRINT "WANT TO CHECK ANOTHER DEAL";
210    INPUT A$
220    IF A$="YES" THEN 80
230 REM: DONE. MAKE A GRACEFUL EXIT.
240 PRINT "THANKS A BUNCH . . . SEE YOU LATER."
250 END
RUN
WHAT'S THE MAG? 73
HOW MANY ISSUES PER MONTH? 1
HOW MANY YEARS IS SUBSCRIPTION FOR? 1
AND HOW MUCH IS IT (IN DOLLARS)? 10

THAT'S $ .833333 PER JUICY, FUN-PACKED ISSUE OF 73

WANT TO CHECK ANOTHER DEAL? YES

HOW MANY YEARS IS SUBSCRIPTION FOR? 2
AND HOW MUCH IS IT (IN DOLLARS)? 17

THAT'S $ .708333 PER JUICY, FUN-PACKED ISSUE OF 73

WANT TO CHECK ANOTHER DEAL? YES

HOW MANY YEARS IS SUBSCRIPTION FOR? 3
AND HOW MUCH IS IT (IN DOLLARS)? 20

THAT'S $ .555556 PER JUICY, FUN-PACKED ISSUE OF 73

WANT TO CHECK ANOTHER DEAL? NO
THANKS A BUNCH . . . SEE YOU LATER.
```

Table 2.

these are mainly advanced features and you'll be in shape to figure them out yourself by the time you get to them.

Third, the books concentrate more on specifics of BASIC than on the more general, problem-solving aspects of programming. That is, they treat a program as an end in itself, without much concern for the facts that when you write a program you're really going to *use* it, that you'll want it to be easy to debug (correct), easy to upgrade later, easy to use in conjunction with other programs, easy to share with other people, etc. All these things mean that it's crucial to be able to write well-organized programs, programs that are easy for *human beings* to understand.

Phase III: Structured Programming

The ideas here will be more understandable after you've written a number of programs. The goal is to make your programs easier for humans (including yourself, of course) to understand by getting you to think about organizing them clearly right from the start.

The general sequence of events in writing a program should be:

1. Make a clear statement (in English) of the problem.
2. Make a flowchart and/or write a verbal description showing the main subparts of the solution and how they fit together.
3. Make a more detailed flowchart or verbal description of each subpart.
4. Once you're sure what each subpart is to do, translate the flowcharts or descriptions into BASIC (or whatever language you're using this week), inserting your descriptions at the beginning of each subpart as comments (REMark statements). This aspect of the programming process is often called *coding*. Note the analogy with coding in radio work — you do want to be able to go from a verbal description (message) to BASIC (Morse) and back quickly and easily, but you don't try to *think* in BASIC (Morse).
5. Don't be satisfied with your first version of a program. Make an extra effort to precede each INPUT or READ statement by a PRINT or REMark which tells exactly what the values will be used for.

Make sure the flow of control is as easy to follow as possible. Indenting groups of statements makes them stand out in the listing, and makes it easier for people to identify important subparts of a program.

Often you will find that rewriting a few statements to straighten out the flow of control will help. People usually find that GO TO statements break their concentration as they look at a program, so if you can find a clear way to redo part of your program so it uses fewer GO TOs, you'll be better off. Here are two examples. The first versions do the same thing as the second ones, but seem easier to follow. See what you think.

```
100 LET X=X+1
110 IF X<=N THEN 50
         :
130

100 IF X>=N THEN 130
110 LET X=X+1
120 GO TO 50

130
         :
```

```
100 REM: A=POSITIVE(X)
110 LET A=X
120 IF X>=0 THEN 150
130    LET A=0
         :
150

100 REM: A=POSITIVE(X)
110 IF X<0 THEN 140
120    LET A=X
130    GO TO 150
140    LET A=0
150
         :
```

The main idea is to be patient, and keep refining your program. You'll make fewer mistakes as you go, your program will be easier to modify, easier to use and easier to understand.

You might think that these suggestions go overboard in asking for neatness and tidiness, that just sitting down at the old keyboard and bashing your program out would be faster and more fun. Try it! Keep track of how long you spend debugging a program compared to how long you spent designing it. Even when you've been very careful, you'll probably find that more time goes into debugging. If your program was a real mess to begin with, you may even find that you *can't* debug it without doing the design phase over again!

Now that we've got all those guidelines under our belts, let's follow through a simple example from start to finish.

Problem Statement:

Figure out the price per issue of a magazine for a number of different subscription offers.

First refinement:

Ask user for magazine name and number of issues per month. Deal: Ask for details of subscription. Figure out cost/issue, print answer. Ask if any more deals to be considered, if so, go to Deal; otherwise, stop.

Second refinement:

See Fig. 1.

(In a program this small, one refinement is probably enough, but the more the merrier.)

In a large program, it's easy to forget what you're doing and use the same variable name for different purposes, sometimes with disastrous results. It's a good idea to make a list of each variable, its type, and what you think you're using it for (see Table 1).

After I coded the flowchart in BASIC, entered it into my computer, corrected a few misspellings, LISTed it and ran it, what I got is shown in Table 2.

You might find it fun to copy this program and modify it. Put in another loop (driven by an appropriate question to the user) which goes back to statement 30 so rates for a different magazine can be checked. Add in wilder messages to the user. Have fun!

As your programs get bigger and bigger, the organizational principles I mentioned become more and more important, and a number of other guidelines become useful. Also, since most of our home computers don't have very much memory to spare, ways of saving space while leaving programs understandable become important. In Part 2 we'll see some of these ideas and we'll go over the design and coding of a bigger program. Meanwhile, happy programming! ■

This magazine is loaded with ads for beautiful computers you can own for the price of a better transceiver. Most have keyboards, CRTs, and tape and disk capabilities. These machines are truly computers. What you can do with them is limited only by your ingenuity. Computers can compute, and store and retrieve data. Tape and disk storage is extremely inexpensive, and you can keep mountains of information on your bookshelf. It would be a shame to pass up getting one of these computers just because you think you'll never be able to program it. Most of these minis use the BASIC language, one of the easiest of all computer languages. My aim in this article is to show you how easy it is to program in BASIC, and to start you off, so that when your new computer arrives you'll be able to make sense out of the manual and start right off having fun.

BASIC was well named. It is very basic, and also very simple. It has a minimum of rules, and is practically the same on every computer that uses it. The differences usually are very slight. For example, one manufacturer requires LIST 200,300 to display program statements 200 to 300 on the screen, while another has you type LIST 200-300. Most of the differences are really added capabilities that one computer has, and that others don't have. So you should still look over the manual before starting to program.

Like any language, BASIC has language elements – components that make up the language. They are *statements, variables, literals, functions,* and *statement numbers.*

Statements are commands which tell the computer to perform a specific task, such as PRINT, or READ.

Variables are items which are assumed to contain a value which can change. They are not necessarily the same each time the program runs. These correspond to the letters used in algebra, like x, y, and z. Their value is usually unknown before the program is started, but, whatever their value is, the program handles a *variable* the same way whenever it is encountered. So, in a program to print a series of addresses, there may be a *variable* to represent zip code. Each address may have a different zip code, but the program does not know, and does not care. It does the same thing with each one. BASIC has two kinds of variables: *numeric* and *string.*

Numeric variables are used to hold numbers to be used in arithmetic. You can add, subtract, multiply, and divide numeric variables. They can contain up to 16 digits. BASIC will not let you put anything but numbers into numeric variables. Numeric variables are represented in BASIC by a letter, or a letter followed by a number. Examples are S or Z1. S can stand for salary, sum, or whatever you want. Z1 could mean zip code or oranges.

Not all data is numbers, however. You may need to represent data containing letters, or numbers, or both. BASIC uses *string variables* for this. They can contain anything. They cannot be used in arithmetic. You represent them by a letter and a dollar sign (e.g., Y$). So N$ could mean *name* in your program, A$ could mean address, and Z$ could be zip code, since it is unlikely you will ever use zip code in arithmetic. There usually is some kind of limit to the number of characters a string variable can contain, but 64 is typical.

Literals are easy. They do not represent anything except themselves. They are taken literally. So "Hi there" means the string of characters "Hi there." Just as there are two kinds of variables, there are two kinds of literals: *string* – letters and/or numbers, and *numeric. String literals* must be enclosed in quotation marks. Everything between the quotation marks is the literal – even spaces. This is the only place where BASIC pays any attention to spaces. *Numeric literals* are never enclosed in quotation marks, and they can be used in arithmetic (for example, 3.14 or 73).

Functions are short cuts built into the language to accomplish things that would be difficult to program (for example, the square root function SQR). Every time you need the square root of a number you say SQR(X) and you get its square root without further ado.

Every line of a BASIC program has a *statement number.* Just put any number from 1 to 999 in front of a basic statement – as, for example, 100 PRINT "THIS IS LINE 100". Remember that BASIC will execute the program statements in order, so statement number 100 will get done before 1020. Usually you number the very first statement 100 and number each line 10 greater than the previous.

When BASIC sees a numbered statement, it assumes it is program code, checks it for

BASIC? What's That?

--the basics of BASIC

Gabriel F. Gargiulo WA1GFJ
17 Whitney Street
East Hartford CT 06118

correct syntax, and enters it into memory. If there is something wrong with it, BASIC will print it on the CRT and point out the error. When you correct it, it is entered into memory.

Let's look at some BASIC and identify the elements found in it.

```
100 LET S$ = "THE SQUARE
    ROOT OF 25 IS"
110 LET A = 25
120 LET D = SQR(A)
130 PRINT S$, D
```

100, 110, 120, 130 are statement numbers. S$, A, and D are variables. You tell me which are numeric and which are string. "THE SQUARE ROOT OF 25 IS" and 25 are literals. You should be able to tell which is numeric and which is string.

You must be eager to start writing your first program. We will be doing that shortly, but we have to learn what the pieces are before we can put them together. We just have to look at some statements, and then it's on to our first program.

PRINT. You have already seen the most useful statement, PRINT. PRINT displays the value of a variable, or a literal, on the CRT.

```
90 PRINT "PROGRAM
   STARTS"
100 PRINT B
110 PRINT "PROGRAM ENDS"
```

LET. LET does more than you would expect. Use it to give a value to a variable.

```
100 LET P = 3.14
110 LET S$ =
    "THE VALUE OF PI IS"
120 PRINT SS, P
```

LET also lets you do arithmetic.

```
100 LET X = 73 + SQR(83)
```

You can make two variables equal with LET.

```
100 LET X = B
110 LET Z$ = B$
```

You cannot mix types. 100 LET X = Z$ is illegal.

LET can even be left out.

```
100 X = B
110 Z$ = B$
```

IF and GOTO. Modifying the sequence of your program can be accomplished through the use of the IF and GOTO statements. You can use IF to test the value of a variable, or to see if it is equal to, greater than, or less than another variable, or an expression. Depending on the outcome of the test, you can skip to another statement in the program. The symbol for "equal to" is =. "Greater than" is >, "less than" is <, and "not equal" to is <>. So if you want to go to statement 5100 if A$ contains "END," write 100 IF A$ = "END" THEN 5100. To go to statement 5700 if A$ and B$ are unequal, write 2100 IF B$ <> A$ THEN 5700. Here is a short segment of a program that will divide R into 4, and print the answer, unless R is zero.

```
100 IF R = 0 THEN 200
(Program sequence modified
using IF and GOTO)
110 B = 4/R
120 PRINT B
130 GO TO 300
(Program sequence modified
using IF and GOTO)
200 PRINT "DIVISION BY
    ZERO IS IMPOSSIBLE"
300 END
```

You are almost ready now. Consult your computer's manual to find out how to get things started. On a BASIC-only computer you may have to do only one thing before keying in your program. You will have to turn on the power. On bigger computers with other languages you may have to type in something like EXEC BASIC before starting. BASIC tells you it is ready to accept program statements by printing "READY" or "OK" on the screen. Then you type in line numbers and program statements. If you type one in that is wrong, simply retype the whole line. To delete a line, type in the line number — nothing more. When satisfied, type RUN and your program will execute.

Here is a short program to try out as soon as your mini arrives. It is called "OHMS LAW." If you give it any two of the three variables, E, I, or R, it computes the unknown.

```
100 PRINT "ENTER E IN
    VOLTS, Ø IF UNKNOWN"
110 INPUT E
120 PRINT "ENTER I IN
    AMPS, Ø IF UNKNOWN"
130 INPUT I
140 PRINT "ENTER R IN
    OHMS, Ø IF UNKNOWN"
150 INPUT R
155 IF E + I + R = 0
    THEN 600
160 IF E = Ø THEN 300
170 IF I = Ø THEN 400
180 IF R = Ø THEN 500
190 GO TO 600
300 E = I*R
310 PRINT "E = ";E
320 GO TO 600
400 I = E / R
410 PRINT "I = ";I
420 GO TO 600
500 R = E / I
510 PRINT "R = ";R
600 PRINT "WANT TO DO
    ANOTHER? Y/N";
620 INPUT R$
630 IF R$ = "Y" THEN 100
640 END
```

Here's a rundown on the few BASIC statements that we haven't talked about yet.

DIM. DIM has nothing to do with the console lights on your computer. It sets up the dimensions (size) of a variable. Most computers establish a default size for each type of variable. Check your manual to find out what it is. You can change the size of a variable with DIM. DIM A$ 30 means that the size of A$ is now 30 characters.

If you have a variable representing a name, and need it to be large enough to hold 30 characters, you had better tell BASIC about it. You do this by using a DIM statement in the following form: 10 DIM N$ 30. DIMs have to come at the beginning of the program, so give them the lowest line numbers.

You can also use DIM to define arrays. An array is a multiple occurrence of a variable. So, if you want N to have 10 different values, you must define N as an array. Use a DIM with the number of times you want the variable repeated in parentheses. DIM N(10) establishes 10 variables in memory, called N(1) through N(10). In the body of your program you can refer to any one of the 10 by putting its number in parentheses after the variable (i.e., a *subscripted variable*). So, to print the fifth value of N, code 10 PRINT N(5). For example:

```
50 N(1) = 3.95
60 N(2) = 7.25
```

This sets the first value of N to 3.95 and the second to 7.25. The numbers in parentheses are subscripts, or indices. Variables can also be used as indices.

```
100 A = 1
110 B = 2
120 N(A) = 3.95
130 N(B) = 7.25
```

This will give the same results as the preceding example.

Here's a short program which stores a series of numbers in an array, then does some computation on each one, and prints out the result.

```
10 DIM F(6)
100 DATA 3.95, 7.25, 14.32,
    28.6, 50.3, 144.4
110 FOR X = 1 TO 6
120 READ F(X)
130 L = 468 / F(X)
140 PRINT L
150 NEXT X
999 END
```

READ. The way data files are set up depends very much on the particular computer. You had better read the manual on this one. There is a simple form of READ, however, which is common to all machines. You include the data to be read in your program, with the DATA statement. Place the DATA statement and its data anywhere

in the program; for example:

```
980 DATA 28.6, 21.37, 14.28,
7.25, 3.95, 146.79
```

Then, to read each item of data, use the READ statement. Each time READ is executed you get the next item in the list.

```
READ F
```

Every time you reach this READ statement, you get the next value in the list placed in the variable F.

You can only reach the READ statement as many times as there are items in the DATA statement. Therefore, in the above example you can only execute the READ 6 times. If you do it 7 times the program comes to a premature end – it aborts.

FOR . . . NEXT. FOR and NEXT go together. For every FOR there must be a NEXT. In combination the two are used to execute a section of your program repeatedly (in other words, set up a loop).

```
100 FOR X = 1 TO 20
110 PRINT X
120 NEXT X
130 END
```

FOR in this example sets X equal to 1. Then control drops through to the PRINT and the NEXT. NEXT adds 1 to X. If X = 20, then control falls through to statement 130; otherwise it goes back to 110. In this example, statement 100 is done 20 times, each time with X being incremented. You can set X to any beginning or ending value (well, almost any value). If you want some number other than 1 to be added to X each time the NEXT is encountered, add the word STEP and the number added to X. So, to set X equal to 32, adding 3 each time, and stopping when X is equal to 73 (or greater) code:

```
100 FOR X = 32 TO 73 STEP 3
110 PRINT X
120 NEXT X
```

The X, or whatever variable you use here instead of X, can be used as an index with an array. This is a handy and efficient way of getting at all the values in an array.

```
10 DIM F(5)
100 FOR X = 1 TO 5
110 PRINT F(X)
120 NEXT X
```

This will print each value of F, one after the other.

INPUT. To get information into the program from the keyboard, use the INPUT statement. Use PRINT to tell the operator what to type in.

```
100 PRINT "ENTER
   VOLTAGE"
120 INPUT E
130 PRINT "ENTER
   RESISTANCE"
140 INPUT R
```

There are some very useful functions in BASIC. However, some of the smaller machines may not have all the possible functions: *RND* to get a random number; *INT* to get the whole-number value of a number; *SIN* to get the sine of a number; *COS* to get the cosine of a number; *TAN* to get the tangent value of a number; *ATN* to get the arc tangent; *LOG* to get the logarithm of a number; *ABS* to get the absolute value of a number. For example, 100 PRINT COS(R) prints the cosine of whatever R is.

BASIC is not only *the* language for the home system, but it is also definitely *the* language for the computer-controlled ham station. In a short time you should be able to develop programs which will keep track of all contacts made to and from your station (date, band, power, rig, etc.), handle mailing lists for your club, compute great circle bearings, convert to and from metric, and on and on . . . the list of applications is limited only by your imagination. Define a problem, and then sit down and write a BASIC program to solve it. Happy computing, and 73s! ■

73 Magazine *Staff*

Is It the Band or My Receiver?

-- the microvolter will tell!

Probably one of the most frustrating aspects of amateur operation for the amateur who does not use his station daily for several hours is to know when his station is functioning properly. That a transmitter is functioning properly can be verified by an in-line wattmeter for power and with a monitor receiver for modulation, at least to see that the rig is basically functioning. An swr check is a good basic check for an antenna system. But, what about the station receiver? An operator who uses his equipment frequently can pretty well judge band conditions on HF and knows that a band is "out." But, the infrequent or weekend operator often checks a band and finds signal levels low and then starts to wonder if it is the band or the receiver. Obviously, various checks can be made to see what the real situation is like. If the receiver can tune outside the amateur bands, stations like WWV or selected shortwave broadcast stations can be used as a quick reference to conditions. If a second receiver of equal quality is available, it can be used for verification of the main receiver's condition. But, many amateurs' entire stations consist of a transceiver confined to tuning only the amateur bands.

In this case, some other means of checking receiver performance is necessary. A signal generator providing a calibrated output down to the microvolt level would be ideal, but few amateurs have such test equipment.

This article presents a different approach in terms of the "microvolter." Basically, it is a simple gadget – just an oscillator and a carefully made attenuator network to generate a signal of approximately one microvolt. It is compact, battery powered and uses a single transistor. But, it can almost instantly remove all doubt and confusion as to whether a receiver is "out" or the band is "out." It was intended to be used by plugging it into the receiver's antenna terminals to make a check. However, it could be placed remotely and connected to its own antenna to see if an entire receiving system were functioning on any given band. Admittedly, there are pitfalls to this latter approach, since when a signal source is close to an antenna system, good signal pickup may occur even though something has happened to the antenna system to change its directional properties.

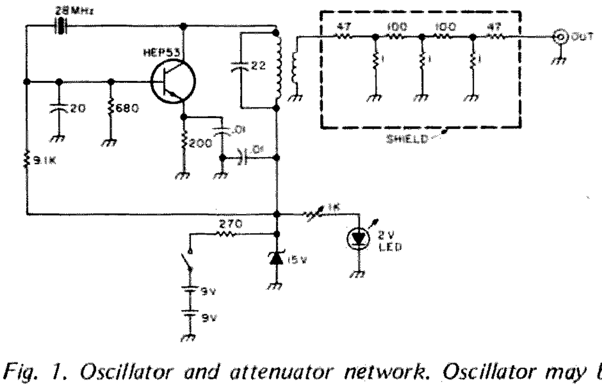

Fig. 1. Oscillator and attenuator network. Oscillator may be used on any band down to 6 meters by proper choice of LC circuit components. Coil: CTC LS5 form, 15 turns #22 enam., with 2 turn link.

The oscillator circuits presented here are mainly for the 20 through 2 meter bands since activity is usually great enough on the lower frequency bands that it is readily obvious if a receiver is functioning. However, if desired, the gadget may be designed to work on any amateur band.

As was mentioned, the microvolter consists of an oscillator and an attenuator network. Many circuits are possible which will work. However, the oscillator must be stable as regards battery voltage, and construction of the attenuator network, while not critical, must be carefully

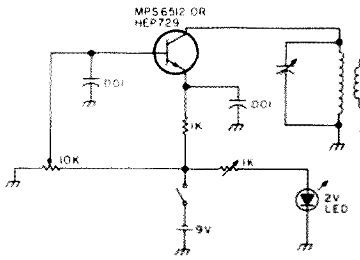

Fig. 2. Extremely simple VFO will work down to 2 meters by choice of proper tank circuit to resonate in desired band.

done to avoid leakage signal paths.

Fig. 1 shows a typical oscillator circuit which can be used and, by proper adjustment of the components, will work from 20 to 6 meters. It is crystal-controlled for simplicity, and the typical component values for 10 meters are shown. Note that the crystal does not have to have any particular frequency, as long as it falls within the band of interest, so advantage can be taken of the various surplus or odd-frequency crystals available at low prices from such outlets as JAN crystals. The output is about ½ volt across 50 Ohms, although this will depend on crystal activity and circuit tuning. The resistor attenuator network shown will bring the output down to about 1 microvolt across 50 Ohms. The output of the oscillator has to be verified in some manner. The best is, of course, to measure it directly if good instrumentation is available. An alternative is to construct the generator and see what response the entire unit provides on a receiver that is known to be in good shape. After all, the main purpose of the instrument is to provide a quick, relative indication that a receiver has not lost sensitivity. If it can be accurately calibrated as to output it could be used to make direct sensitivity measurements on a receiver in conjunction with a VOM to check audio level changes, in dB, with and without the test signal being applied. A simple LED circuit is included both to indicate that the generator is on and to approximately indicate a low battery voltage condition. The pot in series with the LED is adjusted so the lens of the LED is just barely fully illuminated. The difference between this point and no noticeable illumination of the LED is .15 to .2 volts for a typical LED. So, it can serve as a battery voltage indicator better than even a cheap meter.

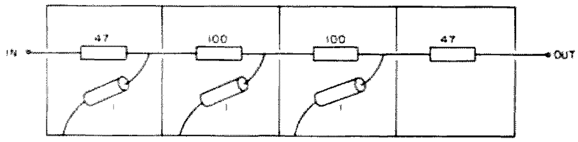

Fig. 3. Attenuator must be separately shielded. The output connector should be mounted on the attenuator shield.

Other crystal oscillator circuits can be used. K1CLL in the August 72 issue of *73* describes in detail a very good oscillator which, among other things, features a simple variable output level scheme by means by varying the emitter bias. For those who do not prefer to make their own oscillator, the International Crystal OX oscillator kits are very suitable. They cost only $3 with a tuned output circuit. The Lo kit takes crystals from 3 to 20 MHz and the Hi kit covers 20 to 60 MHz.

Simple VFOs can be used as the oscillator element but here, of course, the problem is that their output will vary with frequency. Nonetheless, if their output variations can be measured, there is no reason not to use them. For the purpose at hand, ultra frequency stability is not needed, so very simple circuits can be used. Fig. 2, for instance, is about as simple a VFO circuit as can be desired. The frequency of oscillation is determined by the single LC combination. By choosing combinations which resonate in the various amateur bands, the circuit will work down to at least 2 meters. Leads should be kept short and the oscillator enclosed in a metal enclosure to avoid hand capacity effects.

The attenuator network was shown in Fig. 1. Its construction is not critical, but it must be separately shielded even if the oscillator is enclosed in a metal enclosure. The easiest way to do this is by constructing it within a divided enclosure as shown in Fig. 3. The enclosure can be of brass sheet, available at many hobby shops, or of copper sheet, or even of sheeting salvaged from old tin cans. The only objective is to completely "button up" the attenuator network so signal leakage does not occur around it to the output jack of the oscillator.

The unit described has been kept as simple as possible. There are various ways to embellish it, if desired. For instance, three output attenuator networks with different attenuation characteristics might be built: one as a microvolt output, one as an S9 output (usually taken as 30 microvolts), and one as a 40 dB over S9 output. ■

Social Events

EL PASO TX
SEPT 4-5

The ARRL Hamfest will be held September 4-5 at the elegant Vista Motor Inn. Seminars, solar power, exotic modes, OSCAR and flea-market. Write PO Box 24050, El Paso TX 79914. Visit us on Labor Day weekend!

YORK PA
SEPT 5

The 21st Annual York County Hamfest will be held September 5th, rain or shine, 10 miles west of York PA; ½ mile west of York Airport, turn south off Rt 30 to Elickers Grove. Registration begins at 9 am – fee $3.00. All adults and amateurs are expected to register, XYLs and children free. A limited number of flea market tables are available inside by advance reservations *only*. Contact hamfest committee. There will be a $5.00 charge for using electric power. Talk-in 146.04-64; 28-88; 52-52. For more information write or phone Leroy Frey K3POR, 170 S. Albemarle St., York PA 17402, phone 854-1203.

DANVILLE IL
SEPT 5

The Danville Hamfest will be held at Douglas Park, Danville, Illinois September 5. Downstate Illinois' largest. Great prizes. Advance tickets $1.75 ea., 3/$5 with an SASE to Jim Wilson, 308 First, Ridgefarm IL 61870. Talk-in 22/82 and 3910.

BOSTON MA
SEPT 10-12

This year's big New England ARRL Convention has moved back to Boston and will be held September 10, 11 and 12 at the Statler Hilton Hotel. Featuring a bicentennial theme, the convention will cater to the whole ham family, with many committee wives in authentic period costumes helping direct the dozens of special bicentennial events featured in Boston for 1976. The city is extending the welcome mat with special features and exhibits that can only be seen during 1976.

Friday's activities are informal and will enable the ham to relax and "do his or her own thing." They include an FM hospitality suite and a square dance. Saturday and Sunday are crammed with activities from dawn to dusk. FCC exams for General, Advanced and Extra will be given Saturday – by appointment *only*. Application must be made three weeks in advance on FCC form 610 (available from the Boston office of the FCC), accompanied by a check made payable to the FCC for $4. Both check and form 610 must then be sent to Exam Chairman Michael Goldberg K1LJN, 40 Isabella St., Melrose MA 02176 – *not to the FCC*. Applicants will be notified by mail of their exam time.

The New England convention this year will have an emphasis on computer technology and how it affects ham radio. There will be a formal computer seminar on Friday and Saturday, a running computer display by DEC, and forums on computer technology. The FCC will have a booth at the show, along with leading manufacturers and distributors of ham gear. A banquet, show and dinner dance will feature the presentation of the Ham of the Year award on Saturday night.

Special YL activities include a bicentennial fashion show featuring period costumes, a hospitality suite,

and a bus tour of historic Boston (OMs welcome too!). A duplicate bridge tournament will also be a new feature this year.

The extensive speakers' program will feature top personalities, antenna experts such as Walter Maxwell W2DU of RCA, Jerry Sevick W2FMI of Bell Labs, inventor of the strobe light, Harold Edgerton of MIT with Loch Ness monster(!) films, SSTV and computer designer Robert Suding WØLMD, plus special guest speakers on 2 meter FM, DX, SSTV, MARS, an FCC forum, and of course the ARRL forum. There will be talks on solid state, a special program by Fr. Daniel Linehan W1HWK director of the Weston Observatory, net meetings, etc.

One of the most popular events is the flea market – this year it will be indoors, so weather will not dampen the spirits or the equipment!

Early birds can register for $3 (required of all OMs 12 and over); at the door it's $4. Banquet tickets including show and dancing are $12. Send check made payable to F.E.M.A.R.A. and SASE to ticket chairman George Stewart W1ZQQ, 17 Barnes Avenue, East Boston MA 02128, before September 1st.

BEREA OH
SEPT 11

The '76 Cleveland Hamfest presented by the Cleveland Hamfest Association will be held Saturday, September 11 at 8 am to 6 pm at the Cuyahoga County Fairgrounds, Berea, Ohio. Eastland Road entrance only to County Fairgrounds with easy access from Hopkins Airport, Interstate I-71, I-90 or Ohio Turnpike. Tickets $1.50 before August 31; $2.00 at 0800 for all 12 or over when gates open. Asphalt quad flea market parking $1 additional per space at 0700. Bring your own tables and shade. Registration: $1.50 tickets by mail before August 31 with check or money order to: Cleveland Hamfest Association, P.O. Box 43413, Cleveland, Ohio 44143.

MENA AR
SEPT 11-12

The Queen Wilhelmina Hamfest 1976 is Saturday and Sunday, September 11 and 12, at Queen Wilhelmina State Park, Rich Mountain, Mena, Arkansas. Excellent accommodations and food at the newly restored historic Queen Wilhelmina Castle. Door prizes hourly, grand prize, new equipment displays, flea market, camping area with utilities and rest rooms, amusements for harmonics. Talk-in 146.52. For more information write WB5CXX, P.O. Box 5191, Texarkana TX or phone (214) 838-0625.

MELBOURNE FL
SEPT 11-12

The 11th annual Melbourne, Florida hamfest will be held Saturday and Sunday, September 11-12, 1976, from 9 am to 5 pm each day in the air conditioned Melbourne Civic Auditorium located on Hibiscus Boulevard. Donation is $2.50 per adult. Full program includes forums, meetings, auction, swap tables, commercial exhibits, awards, prizes, etc. Talk-in on 25/85 and 52/52. Sponsored by Platinum Coast Amateur Radio Society. For more info write PO Box 1004, Melbourne FL 32901. FCC exams in Ramada Inn Saturday at 8 am for General, Advanced, and Extra. Form 610 and $4 fee must be filed with FCC, Room 919, 51 S.W. First Avenue, Miami, no later than August 31, 1976.

WICHITA KS
SEPT 12

The Wichita Amateur Radio Club Hamfest will be held on September 12, 1976. Registration begins at 8 am at Edgemoore Park (9th & Edgemoore), Wichita KS. Flea market, door prizes, food and beverages on site. Speaker from ARRL Board of Directors. Practice hamfest on evening of Sept 11 at Heritage House in Wichita. Talk-in on 34/94 and 3920 MHz.

Contact KØCFM for further information.

MALAGA NJ
SEPT 12

The South Jersey Radio Assn. 28th Annual Hamfest will be held September 12, 1976, 10 to 5 pm, at Molia Farms, Malaga, New Jersey. Lake, picnic grounds and food available. Tailgate sales, swap shop and door prices. Family tickets: advance sales – $2.50, gate sales – $3.50. Advance sales send SASE to Jack Koch, Box 103, Cherry Hill NJ 08002. Talk-in 146.52.

FINDLAY OH
SEPT 12

The 34th Annual Findlay Hamfest will be held on Sept. 12 at Riverside Park, Findlay, Ohio. Talk-in 146.52. For advanced tickets and/or info write: Clark Foltz W8UN, 122 W. Hobart St., Findlay, Ohio 45840. Please send SASE with request for fewer than 5 tickets.

HAMBURG NY
SEPT 18

The Hamburg International Hamfest will be held September 18, 1976 at the Erie County Fairgrounds in Hamburg, New York. Directions: Take the New York State Thruway to the Blasdell Exit (Exit 56). Recreational vehicles will turn right on Mile Strip Road and turn left on Route 62 South (first major intersection). Follow the signs to the Erie County Fairgrounds entrance. All other vehicles turn left on Mile Strip Road and turn right on McKinley Parkway (first major intersection). Hamfest will include giant flea market, technical forums, picnic facilities, excellent programs, non-amateur displays, code contest, women's programs, organization meetings, equipment displays and FM hospitality room, and thousands of dollars in awards. Admission: $3 at gate, $2.50 in advance. $1 for flea market parking. Children under 12 admitted free. Talk-in stations will be on the WR2ABU repeater (146.31 in, 146.91 out), 146.52 simplex, 7.255 (ECARS), and 3.925. For more information contact Bert Jones W2CUU, 143 Orchard Drive, Kenmore NY 14223, tel. 716-873-3984.

CHICAGO IL
SEPT 18-19

Radio Expo '76 will be held Saturday, Sept. 18 and Sunday, Sept. 19th at the Lake County, Illinois, Fairgrounds, Routes 45 and 120 north of Chicago. Featured this year are an exhibit hall with dozens of displays by amateur manufacturers and distributors, forums with the FCC's John Johnston, *73*'s Wayne Green, ARRL, OSCAR and more. There's a giant flea market with both indoor and outdoor space, plus plenty of room for campers and trailers on the grounds. No waiting in line – the flea market opens Friday night for set-up. No extra charge, either. Talk-in on WR9ABY, 146.16/76, Chicago. Accommodations reserved at the Holiday Inn in Mundeline, Ill., a few minutes south of the fairgrounds. Mention Radio Expo. Advance tickets, $1.50 from Box 1014, Arlington Heights, Ill. 60006.

MADISON WI
SEPT 19

The 4th Annual Madison Swapfest sponsored by Madison Area Repeater Association will be held at Dane Co. Expo Center Youth Building, rain or shine, Sunday, September 19. Doors open at 8 am. All-you-can-eat pancake breakfast, free old-time movies all day long, and lots of prizes. Advance tickets & tables $1.50 – $2.00 at door (XYLs and kids free). Overnite trailer and camper accommodations available at swapfest site. Directions: next door to Dane Co. Coliseum. Just follow "Coliseum" Highway signs to Dane Co. Expo Center, approximately 6 miles west of I-90 and 12 and 18 interchange to "MC" exit. Then turn right on "MC." Coliseum and Sheraton Inn clearly visible ½ mile north of 12 & 18 & "MC" exit. Talk-in on 94. For advanced reservations: M.A.R.A., Box 3403, Madison WI 53704.

HARRISBURG PA
SEPT 19

Hamfest sponsored by the Central

Pennsylvania Repeater Association will be held on Sunday, September 19, 1976 at the Park-N-Shop Parking Garage, 200 Block Walnut Street, Harrisburg PA. Gates will open at 9 am. Registration: $3 per ham, XYLs free — no charge for tailgating. Food available. Note: no vehicle over 7 feet high will fit into the garage. Talk-in 146.16/.76 WR3ABV .94/.94. For more information contact W3ABF or WA3AVX.

MOUNT CLEMENS MI
SEPT 19

The Fourth Annual L'Anse Creuse ARC Swap & Shop will be held on September 19, 1976 at the L'Anse Creuse High School in Mount Clemens, Michigan. Doors will be open from 0900 to 1500 EDST. First prize $200 cash. Talk-in on 146.52 and 146.94. Admission $1.50 at door, $1 in advance. For tickets enclose $1 and SASE and send to Robert Harder WB8ILI, 51769 Base, New Baltimore MI 48047.

NEW KENSINGTON PA
SEPT 19

The Skyview Radio Society's Swap & Shop will be held on Sept. 19, 1976 at the Skyview Radio Club, New Kensington PA. Registration $1. Talk-in 52-52 and 04-64.

McLEAN VA
SEPT 25-26

The National Capitol DX Association (NCDXA) and the Amateur Radio Research and Development Corporation (AMRAD) are teaming together to provide a DXciting weekend — DXPO 76. The 1976 ARRL DX Technical Symposium will present a comprehensive technical session geared to the DXer. Contact Paul Rinaldo K4YKB, 1524 Springvale Avenue, McLean, Virginia 22101 for details. It will be held at the newly constructed Ramada Inn at Tysons Corner near McLean, Virginia. Easy access from Interstate 495 (Capitol Beltway).

NEW BERLIN IL
SEPT 26

The Sangamon Valley Radio Club Hamfest will be held September 26 at the Sangamon County Fairgrounds, New Berlin, Illinois, twelve miles west of Springfield (Illinois state capital) on Route 36. There will be food, programs, covered pavilion, and nearby camping. See Lincoln shrines. Talk-in 28/88 AF9AFA. Tickets $1.00. Write: K9HDZ, 622 Magnolia, Rochester, Illinois.

LEXINGTON KY
OCT 3

The Central Kentucky Hamfest will be held on October 3, 1976 at the Countryworld Convention Center on I-75 between Lexington and Georgetown, Kentucky. Prices will be given away, including a special Novice grand prize. There will also be an indoor flea market. Talk-in on 146.16-76. Admission: $2.50 advance; $3.00 at the door; includes grand prize stub. Doors open at 8 am. For more information and advance tickets write: Hamfest, Box 4411, Lexington KY 40504.

ERIE PA
OCT 9

The Radio Association of Erie has just approved the date for its fall Hamfest and Flea Market on Saturday, October 9, 1976. This year's event will be held at the Kuhl Hose Company Grounds on Pennsylvania Route 8, 1½ miles south of I-90. Admission is free with a $1.00 per car charge for the flea market. The time will be from 10 am to 4 pm with a dinner to follow at 6 pm. For more information contact RAE, Box 844, Erie PA 16512.

SYRACUSE NY
OCT 9

The Radio Amateurs of Greater Syracuse will hold their annual Hamfest on Saturday, October 9, 1976 from 9 am to 6 pm at the Syracuse Auto Auction building on Route 11, 4 miles south of Syracuse. Tickets are $1.50 if purchased before October 1st

and $2.00 thereafter. Food will be available, as well as a breakfast menu for early comers. The Lafayette Apple Festival is being held the same day and there will be buses to it leaving from the hamfest gate. The program will feature Dave Sumner of the ARRL, Frank WB2MFF, on "Microprocessors and Amateur Radio," a UNYREPCO panel, and a Navy MARS meeting. For tickets or further information, write R.A.G.S., Box 88, Liverpool, New York 13088.

VIENNA VA
OCT 24

The AMRAD COMPUTERFEST will be an exposition of microcomputers for computer amateurs, radio amateurs and the general public. It is being sponsored by the Amateur Radio Research and Development Corporation (AMRAD), a non-profit scientific and educational organization.

The AMRAD COMPUTERFEST will be held on October 24, 1976 at the Vienna Community Center, 120 Cherry St., Vienna, Virginia, near Exit 11S of the Washington, DC Beltway.

The exposition will be almost entirely devoted to small computers of the type suitable for home use. There will be displays of microcomputer systems by various manufacturers' representatives as well as tables for used or surplus equipment, circuit boards and parts. Peripheral devices including video terminals, teletypewriters and RTTY equipment will be shown. Forums will run throughout the day on subjects of interest to the serious hobbyist, students, and the general public. There will also be an opportunity to talk to representatives of various computer clubs and magazines.

Admission will be $4.00 at the door ($3.50 advance registration by mail for pickup at the door). Make checks payable to AMRAD. Write: COMPUTERFEST, P.O. Box 682, McLean VA 22101.

For reservations, contact any of these nearby motels directly: Vienna Wolf Trap Motel, 430 Maple Ave E, Vienna VA 22180, (703) 281-2330; Tysons Corner Holiday Inn, 1960 Chain Bridge Rd, McLean VA 22101, (703) 893-2100; or Tysons Corner Ramada Inn, 7801 Leesburg Pike, Falls Church VA 22043, (703) 893-1340.

PLYMOUTH IN
OCT 31

The Marshall County Amateur Radio Club Swap-n-Shop will be held on Sunday, October 31, 1976, at the Plymouth, Indiana National Guard Armory located at 1220 W. Madison Street from 7 am to 4 pm. Free tables, no charge for set-up. Tickets $2 at door. Food, drink and door prizes. Talk-in on 146.07-67 and 146.94 simplex. For further information contact WA9INM, Route 3, Box 526, Plymouth, Indiana 46563.

Tracking the Hamburglar

RUSTLED: TR22-C s/n 120816. Contact Glenn Packard K3ZOT, 836 Mason Avenue, Drexel Hill PA 19026.

TAKEN: Icom IC22A s/n 3402547. Contact Steve Bauer, PO Box 162, Goleta CA 93017.

HIJACKED: Drake TR-72 2 meter FM and locked bracket s/n 750228. Stolen from car in Arvada, Colorado on June 18, 1976. Contact Ron Bradley WBØOES, Arvada, Colorado, 303-421-3549.

ROBBED: Regency HR2 s/n 04-04279, ssn 313-40-1690 on inside frame. $50 reward. Contact Bob Walker W4LPU, 4713 N.W. 3rd Ct., Plantation FL 33317, 305-792-7015.

WHAT HAVE YOU MISSED?

The back issues of 73 are a gold mine of interesting articles . . . just take a look at what's been covered . . . every possible interest. This is the most important library you can have for hamming.

The supply of these back issues is very limited . . . and when these are gone, that will be it. Don't miss out by procrastinating.

Single issues .... $1 each (before 1976)
Ten back issues (your choice) ..... $12 postpaid in US.
Twenty-five back issues (your choice) $20 postpaid in US.
Twenty-five back issues (our choice) $10 postpaid in US.

JUNE 63. Surplus Issue: DMQ-2 Beacon Tx on 220, increasing ARC-2 transceiver selectivity, PE-97A pwr supply conversion, BC-348 band spread, inductance tester, converting BC-230 tx, beginner's rx using BC-453, recvr motor tuning, transistor cw monitor, BC-442 ant relay conversion, mobile loading coils, increasing Two-er selectivity, TV with the ART-26 tx, TRC-8 rx on 220, ARC-5 hf rx & tx, ARC-3 tx on 2M.

AUG 63. Battery-op 6M stn, diode noise gen, video modulation, magic T-R switch, ant gain, halo mods, cw breakin, VEE beam design, coax losses, RF wattmeter, TX Tube Guide, diode pwr supply, "Lunchbox" squelch, SWR explanation, vertical ant info, info on Windom ant.

OCT 63. WBFM transceiver ideas, HF propagation, cheap fone patch, remote-tuned Yagi, construction hints, ant coupler, S5 Vertical, filament xformer construction, 2M nuvistor converter, Lafayette HE-35 mods, Buyer's Guide to Rx & Tx, product detector, novel Hi-C VFO, radio astronomy, panadaptor "if" converter, compact mike amp.

FEB 64. 2M multichannel exciter, rx design ideas, majic t/r switch, loudspeaker enclosures, 40M 2W tx, look at test equipment, radio grounds, 40M ZL Special ant, neutralization.

MAY 67. Quad Issue: 432 Quad-quad-quad, expanded HF quad, Two el quad, miniquad, 40M quad, quad experiments, half-quad, three el quad, 20M quad, tiltover quad, easy-to-erect quad, Quad Bibliography, FET vfo, tube troubleshooting, HF dummy load, under standing "dB," HF SSB/cw rx, geometric circuit design, GSB-201 transceive, FET converter for 10-20M, hi-pass rx filters.

JULY 67. VE ham radio, VE0 hams, dsb adaptor, home brew tower, transistor design, '39 World's Fair, gnd plane ant, G4ZU beam, SSTV monitor, UHF FET preamps, IC "it" strip, vertical ant, VHF/UHF dipper, tower hints, scope monitoring, operating desk, S-Line crossband, hi-school ham club, Heath HR 10 mods.

OCT 67. HF solid state rx, rugged rotator, designing slug-tuned coils, FET converter, SSTV pix gen, VHF log-periodics, rotatable dipole, gamma-match cap, old-time dxing, modern dxing.

JUNE 68. Surplus Issue: Transformer tricks, BC-1206 rx, APS-13 ATV tx, low voltage dc supply, surplus scopes, FM rig commercial xtal types, Wilcox F-3 rx, restoring old equipment, 75A1 rx mods, TRA-19 on 432, freq counter uses, transceiver pwr supply, uses for cheap tape recorders, Surplus Conversion Bibliography, RT-209 walkie on 2M, ARC-1 guard rx, RTTY tx TU.

JULY 68. Wooden tower construction, tiltover towers, erecting a telephone pole, IC AF osc, "dB" explained, ham club tips (Part 1).

SEPT 68. Mobile vhf, 432 FET preamps, converting TV Tuners, xtal osc stability, parallel-Tee design, moonbounce rhombic, 6M xciter (corrections Jan 69), 6M transceiver (corrections Jan 69), 2M dsb amp, ham club tips (Part 3).

NOV 68. SSB xtal filters, solid state trouble shooting, IC freq counter (many errors & omissions), "cv" transformers, space comm odyssey, pulsar info, thin-wire ants, 40M transistor cw tx/rx, BC-348M double conversion, multifunction tester, copper wire specs, thermistor applications, hi-voltage transistor list, ham club tips (Part 5).

JAN 69. Suppressor compressor, HW-12 on 160, beam tuning, AC voltage control, 2M transistor tx, LC power reducer, spectrum analysis info, 6M transistor rx, operating console, RTTY autostart, calculating osc stability, lo-pwr 40 cw tx, sequential relay switching, sightless operator's bridge, ham club tips (Part 7).

FEB 69. SSTV camera mod for fast-scan, tri-band linear, selective af filter, unijunction transistor info, Nikola Tesla biography, mobile installation hints, extra class license study (Part 1).

MAR 69. Surplus issue: TCS tx mods, cheap compressor/amp, RXZ calculations, transistor keyer, better balanced modulator, transistor oscillators, using blowers, halfwave feedline info, Surplus Conversion Bibliography, extra license study (Part 2).

APR 69. 2-channel scope amp, rx preamp, Two-er PTT, variable DC load, SWR bridge, 100 kHz marker gene, some transistor specs, SB-610 monitorscope mods, portable 6M AM tx, 2M converter, extra license study (Part 3).

MAY 69. 2M Turnstile, 2M Slot, rx attenuator, generator filter, short VEE, quad tuning, using antennascope, measuring ant gain, phone patch regs, SWR indicator, 160M short verticals, 15M antenna, HF propagation angles, FSK exciter, KW dummy load, hi-power linear, extra license study (part 4), all-band curtain array.

JUNE 69. Microwave pwr generation, 6M ssb tx, 432-er tx/rx, 6M converter, 2M 5/8 wave whip, UHF tv tuners, ATV video modulator, UHF FET preamps, RTTY monitorscope, extra license study (part 5), building uhf cavities, mini VEE for 10-20M, vhf vfo.

JULY 69. AM modulator, SSTV sig gen, 6M kw linear, 432 KW amp, 432-er tx/rx, 6M IC converter, radio-controlled models, RTTY IC TU, audio notch filter, VRC-19 conversion, tube substitution, 2M transistor xcitor, extra license study (part 6), hf FET vfo.

AUG 69. FET regen for 3.5 MHz up, FM crystal switching, 5/8 wave vertical, introduction to ICs, RTTY tone gen, good/bad transistor checker, 2M AM tx, measure transistor Ft, 160M propagation, triac applications, simple IF sweep gen, transistor keyer, SB-100 on 6M, xtal freq measurement, extra license study (part 7), FM deviation meter, qrp am 6M tx, circular quads, FM noise figure, transistor parameter tracer.

SEPT 69. Tunnel diode theory, majic tee, soldering techniques, wave travel theory, cable shielding, transistor theory, AM noise limiter, AFSK gen, transistor amp debugging, measure meter resistance, diode-stack pwr supply, transistor testing, 2½W 6M tx, HX-10 neutralizing, capacitor useage, radio propagation, AM mod percentage, extra class license study (part 8), 3-400Z linear, ATV vidicon camera, 2 transistor testers, FET compressor, rf plate choke.

OCT 69. Super gain 40M ant, FET chirper, telephone info, scope calibrator, thyrector surge protector, slower tuning rates, identify calibrator harmonics, FM adaptor for AM tx, CB sets on 6M, proportional control xtal oven, xtal filter installation, Q-multiplier, transceiver pwr supply, extra class study (part 9).

NOV 69. NCX-3 on 6M, IF notch filters, dial calibration, HW32A external VFO, 6M converter, feedline info, rf z-bridge, fm mobile hints, umbrella ant, 432-er tx (part 1), pwr supply tricks with diodes, transistor keyer, transistor bias design, xtal vhf sign gen, electronic variac, SB33 mods, extra class study (part 10), SB34 linear improvements.

DEC 69. Transistor-diode checker, dummy load/attenuator, tuned filter chokes, band switching Swan 250 & TV-2, 88mh selectivity, match exercizes, rtl xtal calibrator, transistor pa design, hv mobile p.s., 1-10 gHz freqmeter, CB rig on 6M, extra license study (part 11), 1970 buyer's guide.

JAN 70. Transceiver accessory unit, bench power supply, SSTV color method, base-tuned center-loaded ant, 6M bandpass filter, extra license study (part 12, rectifier diode useage, facsimile info.

FEB 70. 18-inch 15M dipole, 6M converter, high-density pc board, camper mobile hints, 2M freq synthesizer, encoding/decoding for repeaters, DX-35 mods, panoramic vhf rx, variable-Z HF mobile mount, extra license study (part 13), linear IC info, qrp 40M tx, IC Q-multiplier.

MAR 70. Gdo applications, charger for drycells, FM freq meter, pc board construction, ham fm standards, cheap rf wattmeter, multifreq fm osc, "IF" system modules (part 1), Six-er mods, gdo dip lite, Motorola 41V conversion, cw monitor, buying surplus logic, SSO-23A sonobuoy conversion, GRC-9 rx/tx conversion, extra class study (part 14), intro to vhf fm.

APR 70. Noise blanker, 2M hotcarrier diode converter, repeater controller, understanding COR repeater, 7/8-wave 2M ant, extra class study (part 15), inexpensive semiconductors, removating surplus meters, linear amp bias regulator, hi performance if amp & agc system, SSB bfo for shortwave radio, vacuum tube load box, general fm dope & repeater guide, megger-ing your ant.

MAY 70. Comments on "fm docket" #18803, future of cw, fm-am rx aligner, 5/8-wave verticals, using 2M intelligently, auto burglar alarms, pwr supplies from surplus components, "IF" system modules (part 2), vhf FET pre amps, educated "idiot" lites, postage-stamp 6M tx, extra class study (part 16), Bishop (FNL, low-band police monitor, mobile cw tx, Wichita auto patch.

JUNE 70. DDRR ant, vfo circuit, remote SWR indicator, indoor hf vertical, two rx on one antenna, environment & coax loss, 2-el trap verticals, buying surplus, two 40M qrp tx, 21dB 2M beam, extra class study (part 17).

DEC 70. Solid-state vhf exciter, delta-tre control for SSB, 2M transistor FM tx, HW100 offset tuning, "little gate" dipper, 3-500Z hf linear, general class study (part 5), "transi-test" (no good – errors!), transistor p.s. current limiter.

JAN 71. Split fones for dxing, Heath Ten-er mods, cw duty cycle, repeater zero beater, HEP IC projects, 10-15-20M parabolic ideas, lightning protection, IC rx accessory, attic ants, double-balanced mixers, permanent marker tool, ham license study questions.

FEB 71. Metal locator, varactor theory, AFSK unit, SSTV patch box, ATV hints, RTTY tuning indicator, tone encoder/decoder, 220 MHz converter, SSTV magnetic deflection, IC code osc, 6M tx beeper, general class study (part 6), RTTY intro, perf-board terminal, low-ohmmeter.

MAR 71. IC audio filter, IC 6M converter, trap vertical ideas, digi counter info, surplus equip ment identification, hf linear, simple fone patch, repeater audio mixer, digi RTTY accessories, coathanger gndplane, general class study (part 7).

APR 71. Intro to fm, noise blanker, repeater problems, Motorola HT mods, microwave repeater linking, digital ID unit, tuneable 2M fm rx/tx, repeater directory, fm marketplace, meter evaluator, varactor modulator, simple sig gen, touchtone hookup, hf preselector, 10M 12W tx.

MAY 71. 75M mobile whip, 2M preamp, transistor amp design, 10M dsb tx, portable fm transceiver directory, audio compressor-clipper, transistor LM freqmeter, 450 MHz link tx, simple af filter, 1-tube 2M transceiver, surplus 2M power amp, general class study (part 8).

JUNE 71. 2M beam experiments, 3 el 2M quad, multi-band dipole patterns, weather balloon vertical, pocket-pager squelch, two-er vfo, tuning mobile whips, transistor pwr supply, capacity decade box, 40M gain ant, general class study (part 9).

JULY 71. IC audio processor, audio sig gen, cw filter, 2M fm osc, 2M collinear vertical, FM supplier directory, Motorola G-strip conversion, transistor beta tester, general class study (part 10).

AUG 71. Ham facsimile (part 1), 500 Watt linear, dimensions for July collinear, 4-tube 80/40 station, vfo digi readout, Jupiter on 15M, general class study (part 11), pink ticket wave meter.

SEPT 71. Transformerless power supplies, solid state tv camera, IC substitution, two rf wattmeters, IC compressor-agc, multichannel HT-200, ham facsimile (part 2), causes of manmade noise, vfo with tracking mixer, general class study (part 12), transistor heat sinking, IC pulse gen, fone patch isolation, hcd wattmeters.

OCT 71. Emergency repeater cor, transceiver power supply, predicting meteor showers, digi switching, reverse-current battery charger, passive repeaters, earth grounds, audio "tailoring" filters, Swan 350 mods.

NOV 71. 3-el 75M beam, motor-tuned gnd plane, 2M gain vertical, transistor biasing, split-site repeater, fox-hunting, audio filter, transistor/diode tester, xtal tester, 6M kw amp, 10-15-20M quad, transistor pi-net final, ant feedline, communications dbs, 2300 MHz exciter.

AUG 72. SSTV intro, speech processor, fm repeater info, test probe construction, GE progline ac supply, 432 rf testing, preamp compressor, Six-er mods, fone patch, Two-er info, solar info, SCR regulator for HVPS, "ideal" xtal osc, fm rx adaptor, auto theft alarm.

SEPT 72. Plumbicon tv camera, WWVB 60 kHz rx, cigartube sig gen, cw active filter, rf testing at 1296-3500 GHz, balun ant feed, transistor power supply, IC 6M rx, IC fm/am detector (part 2), active filter design (part 3), K2OAW freq counter (part 3), 2M freq synthesizer (part 1).

OCT 72. Corrections for Aug. fm rx adaptor, 2M freq synthesizer (part 2), 6M transistor vfo, nano-ampere meter, time-freq measurement (part 1), active filter design (part 4), repeater timer, extra-class Q&A (part 3), balloon vertical, ID gen, time delay relay, 432 filter ideas, DC-AC inverter, hc diode converter, rtl decade and nixie driver, plus-minus supply for ICs.

NOV 72. Hf transistor power amps, RTTY selcal, IC trf rx, transistor keyer, emergency power, 220 MHz preamp, double-delta ant, simple converter using modules, hf RF tester, "lumped line" osc, 2M freq synthesizer (part 3), K2OAW counter errata, 2M preamp, extra class Q&A (part 4), hi-Z voltmeter, Nikola Tesla story, vhf swr meter, transistor regen rx, 432 SSB transverter, AC arc welder, intro to computers, hybrid am modulator, HR10 rx mods, 10M transistor am tx, 40M gndplane, IC logic demonstrator, overload protection, if/rf sweep generator, digi freq counter, aural tx tuning.

DEC 72. SSTV scope analyzer, 2M fm rx, tone burst encoder and decoder, universal if amp, autopatch hookup, LM380N info, voltage variable cap info, 2M 18 watt amp, SSB modulation monitor, xtal freq/activity meter, 10A var. dc supply, transmission line uses, radio astronomy, inductance meter, 75 to 20M transverter, LED info, 40M preamp, transistor vfo, 1972 index, 2M preamp.

JAN 73. HT-220 touchtone, 3-el 20M vagi, 50 MHz freq counter, speech processor, 2-tone gen, fm test set, tilt-over tower, 6M converter using modules, tuneable af filter, six band linear, 10M IF tuner, diode noise limiter, cw/ssb agc, HW22a transceiver 40M mod, HAL ID-1 mod.

FEB 73. CW id gen, tone operated relay, toroidal quadrature ant, active filter, time freq measurement (part 2), repeater timing control, SSTV circuits (part 1), 2M converter using modules, multifunction metering, FET biasing, freq counter preamp, TR22 hi-power mod, transistor rf power amps (part 1), light bulb rf power indicators, 75A4 filters, capacitance measurement, Gonset 201 mod, world time info.

APR 73. FM deviation meter, 2M FET preamp, two 2M power amps, repeater control (part 1), repeater licensing, European 2M fm, fm scanner adaptor, RCA CMU15 mods, lightning detector, cb alignment gadget, transistor rf power amps (part 2), repeater economics.

JUNE 73. 220 MHz sig gen, uhf power meter, repeater licensing info, RTTY autowitch, 40M hybrid vfo tx, ant polar mount, 10-15-20M quad, K2OAW counter mods, double coax ant, ham summer job, tone decoder, field strength meter, nicad battery pack, ohm meter, FCC regs (part 1).

AUG 73. Log periodics (part 1), tone burst gen, rf power amp design, transistor radio intercom, 160M ant, SSTV monitor, low cost freq counter, VOM design, qrp 40M tx, 432 MHz exciter, fm audio processing, FCC regs (part 3).

SEPT 73. Repeater control system, log periodics (part 2), 2M rx calibrator, PLL ic applications, TT pad hookup, Heath HW7 "s" meter, Oscar-6 doppler, 2M coaxial ant, 2M converter, IC keyer, measure ant Z, FCC regs (part 4).

OCT 73. GE Pocketmate mods, microwave freq measurement, CA3102E 2M frontend, 2 kw hf linear, rf wattmeter, meter repair, 60/40 dipole, IC "hi" gen, vhf freq multiplier, FCC regs (part 5).

NOV 73. 450 MHz exciter, intro to ATV circuits, nicad voltage monitor, autopatch connections, IC meter amplifier, TR22 ac supply, indoor vertical, IC af filter, momentary power failure protection, 160M ant acoupler, Motorola HT info, SSTV ISB, Class-B af amp, FCC regs (part 6).

DEC 73. Code speed display, 2M kw amp, IC keyer, 8038 waveform gen, helical resonator design, sencitive rf voltmeter, proximity control switch, IC tester, sequential tone decoder, 2M portable beam, electronic calculator math, cw filter design, FCC regs (part 7).

FEB 74. SSTV monitor info, IC audio amps, scope sweep gen, 15/20M vertical, telephone line control system, pc board construction, var-Q af filter, blown-fuse indicator, 40m cw stn with Ten-Tec modules, simple preamp-compressor, single IC rx, "432-er" final assembly, transistor keying circuit, 7 segment readout with nixie driver.

APR 74. Vox for repeaters, tone operated relay, hf transverter, 10-to-2m tx converter, remote control panel for scanner, RCA fm tx tuning, subaudible tone gen, FCC regs (part 9), Repeater Atlas.

MAY 74. Cd car ignition, audio compressor info, interference suppression for boats, auto burglar alarms, 2m ic preamp, 10m fet converter.

JULY 74. 4-1000A linear, universal freq gen, universal afsk gen, 555 IC timer, 80M phased array, 135 kHz-432 MHz preamps, 10M qrp am tx, 3000 vdc supply, how to read diagrams.

AUG 74. Toroidal directional wattmeters, 450 MHz FET preamp, use gdo to find "c", Trimline tt pad hookup, R390 & R392 rx mods, tracking cw filter, aural voltmeter, universal regulated supply, sstv scan converter, ttl logic problems, ID timer.

SEPT 74. MOSKEY electronic keyer (part 1), ex warning system, Heath 10-103 scope mods, qrp 6M am tx, rf speech clipper, audio noise limiter, wx satellite on SSTV monitor, universal IC tester, miniature rig construction, tower construction, infinite rf attenuator, electronic

(More)

Since there's little to get stale in back issues of 73 (our magazine is not padded . . . like others . . . with reams of activity reports), you'll have a fantastic time reading them. Most of the articles are still exciting to read . . . and old editorials are even more fun for most of the dire predictions by Green have now come to pass. Incentive licensing was every bit the debacle he predicted . . . and more. You'll really get a kick out of the back issues.

photo flash ideas, IC "select o ject."

OCT 74. Microtransistor circuits, synthesized HT 220 (part 1), repeater government, regulated 5 vdc supply, fm selcal, removeable mobile ants, Motorola metering, 2M vertical collinear, Motorola model code, 2M coaxial dipole, 1.6 MHz if strip, MOSKEY electronic keyer (part 2), carbon mike circuit hi power lo pass filter, 6M preamp, 3-wire dipole ATV sync gen, NCX 5 mods, mobile whip for apartment dwellers, sstv auto vertical trig

NOV 74. K2OAW counter update, regulated 5 vdc supply, wind direction indicator, synthesized HT-220 (part 2), 20M 3-el beam, auto patch pad hookups, double-stub ant match, novice class instruction, digi swr meter (part 1), 6M converter (1.6 MHz if), "C-bridge," MOSKEY electronic keyer (part 3), Aug. sstv scan converter errata, repeater off-freq indicator.

DEC 74. Care of nicads, wind speed/direction indicator, wx satellite video converter, electronic keyer, hints for novices, unknown meter scales, SSTV tape ideas. TTL logic probe, public service band converter, tuned-diode test receivers, digi swr meter (part 2), telephone pole beam support, rhombic antennas, 1974 Index

FEB 75. Heath HO-10 scope mod for SSTV, electronic keyer, digital satellite orbital timer, Oscar-7 operation, satellite orbital prediction, Heath SB-102 mods, comparing FM & AM, repeater engineering, Robot 80-A sstv camera mod, neutralizing Heath SB-110A, "Bounce-less" IC switch, tape keyer for cw tx.

APR 75. $50 walky for 2M, 2M scanning synthesizer, 88 mH toroid info, 8-function repeater controller, nicad battery precautions, TR22C preamp, telephone attachment regs, Guide to 2M Hand-held Transceivers, 2M 7-el beam, basic telephone systems (part 1) 10 min ID timer, modified hf Hustler mobile ant for 2M, 15M quad modified for 20M, 2M collinear beam, R 11A surplus rx conversion, 5/16 wave 2M ant, Hallicrafters SX 111 rx mods, 160M cw tx.

AUG 75. 146/432 MHz Helical ants (part 2), 10 min ID timer, digi swr computer (part 1), debugging rf feedback, DVM byer's guide, wx satellite monitor, cmos "accu keyer," pc board method, sweep-tube final precautions, compact multiband dipoles, small digital clock, accessory vfo for hf transceiver, modern non Morse codes, multi-function gen, 2M scanning synthesizer errata, KP-202 walky charger, 10M multi element beam.

SEPT 75. Calculating freq counter, wx satellite FAX system (part 1), IC millivoltmeter, three-button TT decoder, troubleshooting sstv pix, 40M dx ants, 146/432 MHz helical ants (conclusion), digi swr computer (conclusion), reed relay for cw bk in, NE555 preset timer, power failure alarm, portable qrp rig power unit, precision 10 vdc reference standard, 135 kHz if strip, telephone handsets with fm transceivers, Motorola T 44 tx mod for ATV, 0-60 MHz synthesizer (part 10, ham radio PR)

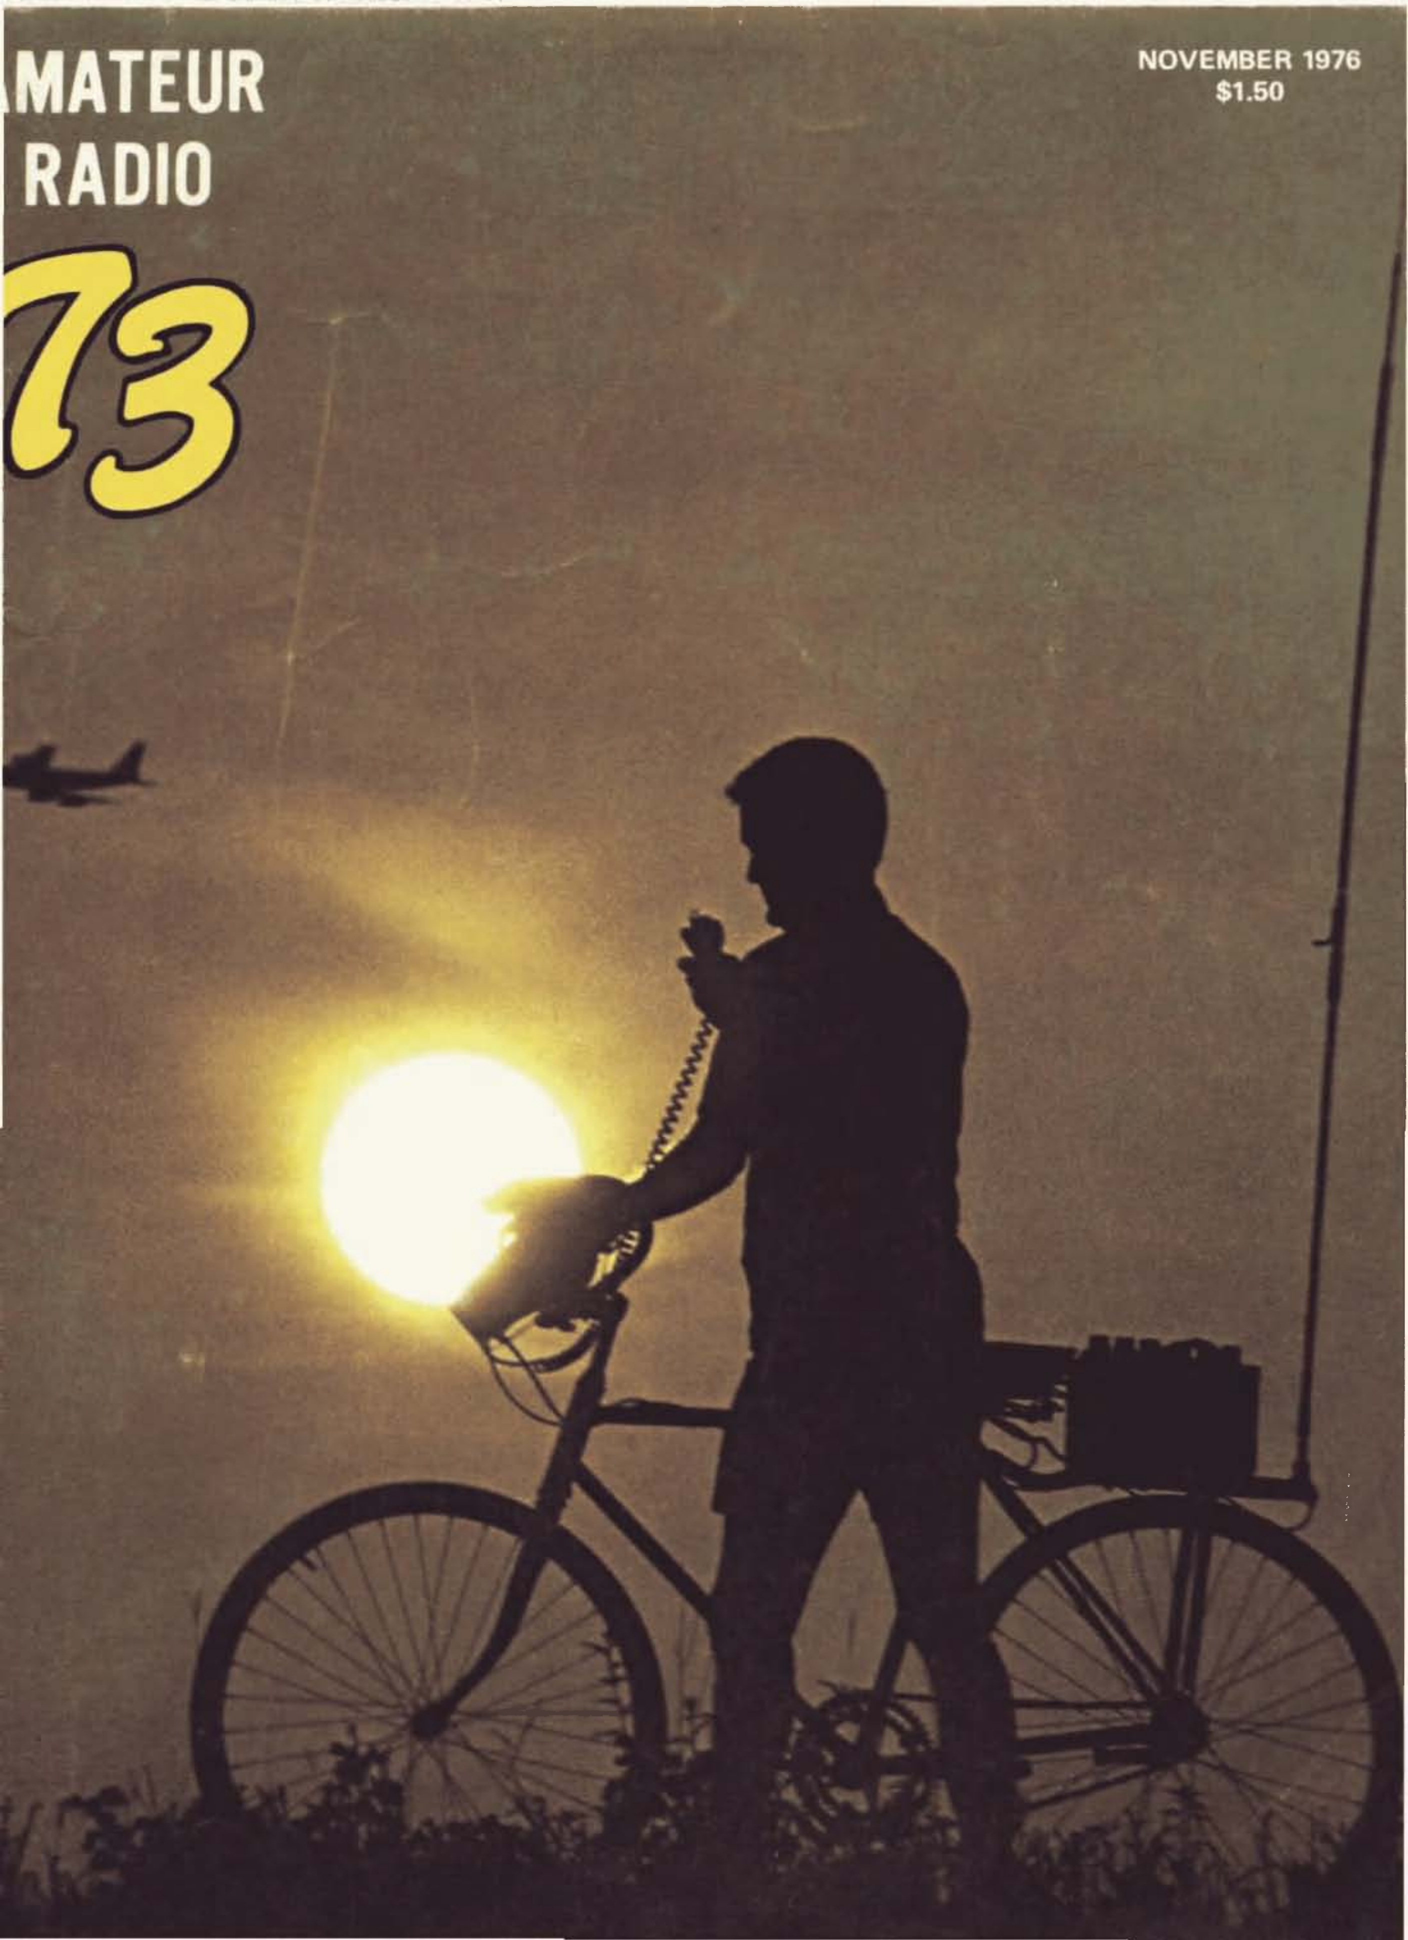
NOVEMBER 1976
$1.50



THE 2-VOLUME WEBSTER'S 9-POUND, 1,380 PAGE, 158,000-DEFINITION $39.95 DICTIONARY

NOW ONLY $19.95!

Can you imagine **The New Webster International Dictionary of the English Language** as a victim of recession? It is true! And just as the automakers offered rebates to drastically improve sales, so does Webster announce an incredible half-price slash of the publishers list price of $39.95 to an unbelievable $19.95 on the 1,380-page, nine-pound, 158,000-definition, 196-page supplemented, 2-volume, 1976 edition of **The New Webster International Dictionary of the English Language**. Now Only $19.95.

Think of it! This 2-volume reference work for home, school or office library has never before been offered at such an extraordinarily low price. The many years of exhaustive research are clearly reflected in this supreme lexicographic effort. From this research and from suggestions, contributions and critical review by such notables and men of letters as Charles C. Collingwood, Chief Foreign Correspondent, CBS; Radio and Television Commentator and Mark Van Doren, PhD.; Author; Poet; Professor Emeritus of English, Columbia University, a most respected and distinguished permanent editorial staff labored unstintingly for additional arduous years to give you what has culminated in this priceless, non-pareil etymological endeavor. Everyday, literally hundreds of thousands of people refer to **The New Webster International Dictionary of the English Language.**

The work itself is a joy to peruse and is printed in large, easy-to-read type. It begins with A Historical Sketch of the English Language by Mario Pei, Professor Emeritus at Columbia University. The vocabulary, A-Z, is included in 1,185 pages, with even the most modern of colloquialisms well defined. This section is prefaced with A Guide to the Use of The Dictionary and tables for the pronunciation symbols and abbreviations used therein. Also included is a dictionary of Prefixes and Suffixes with etymologies and meanings.

Noah Webster (1758-1843). Father of lexicography and inspiration for founding of our company.

Other supplements include:

- A phenomenal 51,000-word thesaurus of Synonyms and Antonyms with 4,000 precise cross references—an invaluable adjunct that no dictionary can be without.
- Idiomatic Foreign Words and Phrases—French, Latin, Greek, Spanish, Italian, etc., pronounced and translated into English—a must with our present day emphasis on multilingualism.
- Over 2,500 abbreviations set forth and defined—an acronymic treasure house.
- Musical signs, symbols and abbreviations set forth and explained for even the novice.
- Your knowledge of popular and famous quotations lends credence to your literary background. Hundreds of these priceless comments on a myriad of people, places and things makes this section, in many ways, the crown jewel of supplements. "The wisdom of the wise, and the experience of the ages, may be preserved by quotations."—Disraeli.
- Seven sections comprise the Students' and Writers' Guide; truly a complete reference in itself for high school, college, home and office. The pen is still mightier than the sword!
- Do you want an exact date between 1901 and 2100 AD? This precise, simple, perpetual calendar will keep you ahead of the times, up to date or behind the times. You'll always have the right date.
- Metric or United States (Imperial)—we're here to convert you—and make it quick and easy—in our world of number systems such conversion tables are a necessity.
- Our Occupational Guide lists dozens of jobs and professions with appropriate explanations of necessary training, salary ranges and job availabilities, etc. PLUS an extensive listing of National organizations and addresses that can lead you to the job of your choice.
- The awe-inspiring adventures of both Greek and Roman mythology are detailed in abridged form with appropriate cross references. Constant literary reference to these immortal people and stories makes this section a storehouse of interpretive information.
- The Secretaries' Guide and Manual of Information is a commercial course in itself. It holds the key to being a successful secretary giving detailed and explicit information on the position, office routine, letter writing and filing with complete, accurate and up to date subdivisions for each.
- Multiplication and Compound Interest Tables will ease your way through our "buy it on the installment plan" life. Precise, simple and accurate—if you don't pay cash, know what your purchase costs really are.
- Keep track of your own wages and salary. Timekeepers do make mistakes. These simple, accurate tables permit you to swiftly discover errors of computation in time spans as small as 15 minute periods.
- Most of our lives we eat, sleep and work by the clock. Our magnificent charts will swiftly show you the exact time, on a comparison basis, anywhere in the world—all 24 time zones are at your fingertips.
- 8 pages of exciting, colored reproductions of the flags and banners of the world—a real history lesson.

And now all this can be yours. Two huge, handsome volumes that set on a library shelf will add a touch of grace, splendor, knowledge and erudition to your office or den. **The New Webster International Dictionary of the English Language** has never before been offered at such an astonishingly low $19.95.

Here is our no-risk offer. Send for this beautiful dictionary of dictionaries today. Keep it for 14 days. Thumb through it as often as you wish. You must agree that it is the most thorough and comprehensive dictionary ever published, the one that defines every subtle nuance of a living, pulsating language—or return for a prompt and courteous refund.

The New Webster International Dictionary of the English Language, which lists at $39.95 is now only $19.95. Add $2 for shipping. Hurry and order today. Credit card buyers may phone us toll free at 800-241-8444. Ask for Operator 516. In Georgia Only it is 800-282-1333. In Canada it is 1-800-261-6362. Or you may mail payment with the coupon below.

This recession-induced, money-raising, half-price sale may never be repeated. Write or call now while supplies last. Our toll-free lines are open 24 hours a day, 7 days a week. Allow 3-8 weeks for delivery.

NEVER SAY DIE

. . . de W2NSD/1

EDITORIAL BY WAYNE GREEN

WD CALLS STARTED

The FCC has started issuing WD4 calls, so don't be surprised or think they are just special events calls. What happened to WC calls? These have been reserved for RACES stations and are being bypassed for general ham licenses.

PARKING SOLUTION

The parking lot for the downtown Hartford shopping complex has a special section for CB radio parking . . . right under the watchful eye of the cashier at the exit. This looks like a good solution to the problem of getting CB and ham rigs ripped from your car. You might show this picture to your local parking lot manager and see if he won't provide a similar service.

ATLANTA 73 BOOTH VISITORS

Some well-known hams stopped by the *73* booth at Atlanta and got their pictures snapped.

FCC WRONG

During a discussion on a San Francisco radio talk show a couple weeks ago, I faced the head of the FCC for the area telling me that CB was just awful there . . . bad language . . . a mess. He said that CB might be okay back East where I lived, but I would disown the whole thing if I heard how it was in California.

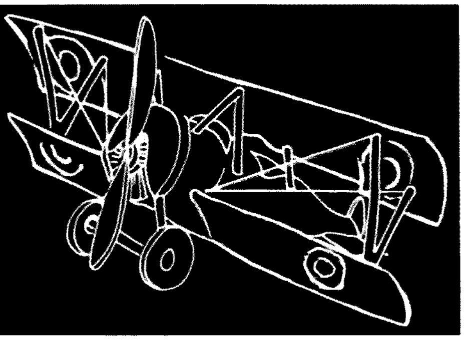
Autobiography of an Ancient Aviator



W. Sanger Green
1379 E. 15 Street
Brooklyn NY 11230

I returned to Genoa after a 16 day survey trip to Marseille and the northwest African coast. Genoa felt like home – but not for long. I had three days to make up my report and get ready for a trip to Egypt and the Levant. On January 12th, Jim Eaton flew down to Rome with me on Ala Littoria. Since we arrived late, we just had time to check in at the Ambassadore and have a quick dinner before an evening conference with our Commercial Attaché. This was interesting, as he appeared to know more about Export's plans than Export did. After he finally bought us a drink, we retired.

My schedule was to take the 05:30 Ala Littoria plane from Rome to Brindisi (about 300 miles), arriving there in plenty of time to catch the 10:30 Imperial Airways (British) flying boat to Alexandria via Athens. All very fine. Up at 03:00, shower and shave in haste, no coffee, bus to the 20 mile distant airport, no coffee, bumpy ride to 09:10 arrival at Brindisi, and still no coffee. Then, finally, breakfast at the International Hotel. Then I found that Imperial Airways would be a day late: "Be in some time tomorrow morning." What do you do with a day at your disposal in Brindisi?

That question was solved for me by what you might call a coincidence. Just as I was leaving the Imperial Airways office at the airport I heard well-raised voices in an adjoining room, some Italian and one American that I recognized as that of an old friend – Wesley Smith from Philadelphia. It seems that a fellow named Welch had shipped his plane over to Le Havre and had hired Wes to fly it and him from there to Saigon. They had arrived at Brindisi that morning and had planned on going on to Athens after refueling. The Italian officials had different ideas. Some technicality was preventing them from clearing Wes's flight. Their negotiations were apparently quite difficult due to the Americans not understanding Italian and vice versa. I butted in and helped get matters cleared up by getting the Imperial Airways Station Manager to act as interpreter. By that time, however, it was too late for Wes to start for Athens, so Wes, Welch and I had an enjoyable evening together "on the town." They got away early the next morning, but my 10:30 Imperial Airways flying boat didn't arrive until 13:00. Accommodations and service on Imperial were the best, and we had a good flight to Athens. Wes and Welch were already checked in at the El Brittan Hotel when I arrived, so we had dinner and a night club together. Next morning I had a stormy and very bumpy three hour crossing to Alexandria. Jim McCormack (Export's Near East representative) met me at the flying boat station and settled me in at the Windsor Hotel.

I have a couple of clippings from the Egyptian Gazette (Alexandria) following up the Smith-Welch Saigon flight story. Both dispatches were from Nicosia, Cyprus. The first, dated 1/16/37, reported that Smith and Welch had arrived there at 07:30 that morning after a flight of nearly 600 miles from Athens, and that "The recent rains having left the Airdrome in a very muddy state, the wheels of the machine became embedded in the ground when landing, but were later extricated and the plane was found to be undamaged." The second, dated 1/18/37, stated that Smith and Welch "left at 10:15 for Damascus. The airdrome officials witnessed the takeoff which they believed to be impossible owing to the muddy state of the ground, and they held fire extinguishers ready in case of emergency." I have talked with Wes about this trip several times since at Quiet Birdmen meetings in New York.

I found that Jim McCormack had a fairly tight schedule arranged for me. My first evening in Alexandria he took me out to Judge Brinton's home after dinner to obtain his advice on how to proceed with my mission in Egypt. The judge was an American and for years had presided over the "Mixed Court" in Alex. He was very friendly and advised us not to talk with any Egyptian officials at that time, but to put the matter before Mr. Childs, our Consul, and the Minister (don't remember his name) in Cairo for our guidance. So we made an appointment with them for Sunday afternoon, January 17th, and rode the railway up to Cairo. They told us that since the August 1936 Anglo-Egyptian Treaty which turned the government of Egypt back to the Egyptians, most of the new government's efforts had been directed at replacing British civil servants with Egyptians. They thought that the time was inopportune to try to talk with them about air rights. Their advice was to wait a few months until things had settled down a bit. With this, my business in Egypt was concluded for the time being. I still had Haifa and Beirut to check, but had to wait until January 23rd for the Exochorda (one of Export's Four Aces) to make the trip up the Levant coast and back. A brand new Chevrolet sedan belonging to John Gehan was unloaded from the Exochorda at Alex. It already had Italian number plates on it and a note from John Gehan told me that it was completely insured and to use it as much as I wanted to. I didn't have an international driver's license (don't even know whether they were available at that time), so I took out an Egyptian driver's license and drove all around Alexandria as well as to Rosetta, Damanhur and other native villages. Driving through a native village was a pretty slow process in those days. No amount of horn blowing, yelling or nudging would get a person, donkey or camel to move over to let you pass – particularly in a narrow street. Small boys would jump on your running board, some for the ride, but mostly to yell for alms.

Alexandria is pretty well surrounded by water with the Mediterranean on the north, Lake Mariut on the southwest and Lake Idku on the east. Both these lakes were too shallow for flying boat operations. It wouldn't take much wind to build up too much of a sea. Imperial Airways used the ship harbor which was well protected, so I decided to recommend that for our use.

Speaking of Lake Mariut reminds me of the novel way of catching wild ducks that was practiced in the lake. As I mentioned before, Lake Mariut was quite shallow in places. Several Egyptian young men equipped with weighted shoes, a hat with a lot of reeds or rushes sticking up from it, a wide belt with cord loops attached all around it (20-25) and five or six live decoys with strings attached to one leg, would wade out in the lake until the water was nearly up to their chins and have the decoys swim around near their hats. Cruising wild ducks would spot the decoys and join them. When one got close enough, the hunter would grab its feet and pull it under water and attach its feet to a loop on this belt where it would drown quickly with a minimum of commotion. When his belt was full he would bring them into the city (Alex) and sell them for anywhere from 10 to 20 Piasters each (50¢ to $1), according to the buyer's bargaining ability. They were mostly small black ducks and were delicious if not overcooked. Guess I better stop here and not get into any cooking directions.

Next month: Jerusalem to Beirut in 1937.

visiting views from around the globe

Belle

Hurricane Belle turned out to be much less of a storm than expected. But Civil Defense officials and radio amateurs from South Carolina to Maine were ready. By the time Belle, packing 80 mile an hour winds, hit Long Island and Southern Connecticut on the eve of August 9th, local CD directors and their ham helpers had as much as four days' notice.

In most areas, 2 meter repeaters furnished the first line of communications. Here in New Hampshire, for example, the Concord 34/94 (W1ALE) was taken over by the state Civil Defense, led by W1EDU, who set up a 2 meter control base at the Concord Armory. 34/94 then became the primary link for the entire state CD. That was more than twelve hours before Hurricane Belle, in a much toned down form, rolled into southern New Hampshire.

On the lower bands, weather and Red Cross nets were the order of the evening, with SSB taking the biggest load. CW nets were started up, but the volume of takers was insignificant compared to the SSB nets. Northeastern University Club Station W1KBN utilized an FCC designated emergency frequency at 3910 and dispatched net controls plus liaison stations at ten kHz intervals according to state. It was possible to tune any area, any state and get the latest track on Hurricane Belle. Meanwhile some states had started their own nets, extending the earlier established 2 meter FM nets.

ARRL Memorial Station W1AW jumped from net to net, gathering the latest information, and passing it along to the rest of the country by Official Bulletin. *73* staffers WB6BED/1 and WA1GUD/1 manned 75 meters for New Hampshire until nearly 0200 local time.

It was something to behold – 2 meters and the low bands linked by control stations, tying the entire eastern seaboard together with emergency communications, much of it on emergency power. Through the next day, August 10th, local groups continued their vigil, watching over swollen streams and rivers, and assisting in the few evacuations that were necessary.

Many local CD officials first heard the course of the storm from hams monitoring on the low bands, and relaying word by 2 meter FM. CBers too played their role, furnishing coordination between emergency officials and Red Cross groups. There were only a few reports of problems between CB and amateur groups, but they were promptly cleared up after some ham diplomacy and a demonstration of what 2 meters could do. It was easy for local police and fire officials to draw a comparison between their own FM Public Service communications and the amateur systems.

So, if Hurricane Belle is to go down in the amateur radio record books, it would have to be a measure of just how well prepared we are. Despite the lack of a life and death emergency in the long run, New England's experience with Belle proves amateurs are ready and able to furnish immediate and reliable communications. But it is a lesson as well in the value of advanced warning, and the need for continued planning at the local, regional and national levels.

Dixie

Dave Blackmer, the retired Air Force man who lives in Nipomo, is an amateur radio buff. He has his own 1,000 Watt station, WA6UNK, and spends countless hours talking with and listening to people around the world. He was thus engrossed last Thursday afternoon, moving his dial to see what was going on.

Suddenly there came an SOS signal from a yacht off the coast of Baja California. The yacht, becalmed and with an ailing and idle engine, had aboard a man who appeared to be suffering from a heart attack. His wife was at the radio transmitter, sounding her emergency call.

Dave latched on. Next thing he did was to get a telephone patch to Marian Hospital's emergency ward, where Dr. Carl D. (Doug) Shaw was on duty. For about 15 minutes Doug and the stricken man's wife discussed the case and he advised her. Then came an emergency at Marian and Dough had to attend to that, so Blackmer now patched the woman into Arroyo Grande Hospital and Dr. Carl Shirk.

The woman (her name is Dixie but the amateur radio buffs don't use last names) read off to Carl the list of contents in the yacht's emergency kit.

"You've got everything you need right there," the doctor told Dixie. Then he told her how to administer a shot and otherwise care for her husband.

Meanwhile, an amateur radio operator in Panama City and one in Uruguay picked up on the conversations and posted themselves above and below the wave length in use, to keep others from butting in and interfering. Also, a ship in the neighborhood locked in on the conversation and made it to the disabled yacht to take the patient (he had strained himself lowering the anchor) to shore.

Dave, in the middle of all the excitement, doesn't know how it all ended. Just at this point the wind blew over a tree in Nipomo, cutting off his power. When service was restored, the emergency was apparently over and the airlanes were quiet.

Aloha

Tony Tamosaitis K1VTE of 147 Neal St., Malden, Massachusetts, provided a unique way for ham radio operators in seven states to celebrate our country's 200th birthday.

On Sunday, July 4, originating at 5 pm local time (11 am Hawaii time), the 19/79 amateur radio repeater WR1ACO located at Beachview Ter., Malden, was linked simultaneously with WR6AGE in Honolulu, Hawaii and WR3PHL in Valley Forge, Pa. After establishing the link-up, network control stations asked for a roll call from the three repeaters. Amateur radio stations from Massachusetts, Maine, New Hampshire, New Jersey, Pennsylvania and the first and fiftieth states respectively, Delaware and Hawaii, checked in to begin communications.

Also included in the Hawaiian link were the smaller islands of Maui, Molokai and Oahu.

One of the first stations into the Hawaii system was WA1SQR marine mobile aboard the *Fifth Amendment* off Cape Ann exchanging greetings with KH6IPN in Honolulu. Throughout the evening, base stations, marine mobile, land mobile and hand-held walkie-talkies communicated and exchanged greetings from the East Coast to the West Coast.

The high point came early in the four-hour link-up when AA8ARV/KH6 transmitted the following message: "This is AA8ARV portable six, hand-held walkie-talkie in Waikiki. The Lieutenant Governor of the state of Hawaii, Nelson K. Doi, has asked me to extend to all stations participating in this historic link-up of the East Coast with the West Coast of the United States and the first and fiftieth states in the Union, and other historic places, his warmest congratulations. The Lt. Governor is well aware of the contributions of ham radio not only to the local communities, but also to our nation. And in keeping with the spirit of our Bicentennial, he extends warmest aloha to all stations and operators participating in today's historic link-up. This is AA8ARV portable six Waikiki ... back to KH6IPN Hawaii control."

The Hawaii link was terminated at 8:45 pm and communications through the Philadelphia link continued until

9:15 pm when this link was terminated.

The stations handling net control duties were as follows: Tony Tamosaitis K1VTE, assisted by Tom Cook K1OCD, handled the Hawaii input at the Beachview Ter. repeater site, and also the Philadelphia input fed in from a remote station operated by Alan Carp K1HLZ, assisted by Frank Carp WA1RIY, both of James St., Malden, Mass. Net control operators in Philadelphia were Jesse Wagner K3GKB, assisted by Bill K3JPB. In Hawaii Don Blaisdell KH6IPN was assisted by Steve Gross KH6HGG.

Giving Nothing and Expecting Nothing

One of the local QRpers came by last week and we sat in the sun to watch the bees work hard to make a living. The well-aged QRPer was a bit restless, and we thought we knew the answer. "Been reading 'Silent Keys' in *QST* again?" we asked, and the QRPer nodded. After a bit he spoke. "This DXing has always been an unusual thing to me," he said. "A DXer makes an acquaintance that may be thousands of miles away, in another country, and with the odds that most will never meet face-to-face. Yet there exists a bond and that feeling of loss when they are no longer with us. Why is that?" In turn, we held our own silence, for the feeling has often come to us also. Finally the QRPer spoke again. "I have long felt that DXers offer what is closer to true friendship than any other activity. We meet another DXer on the air, we give nothing and expect nothing. Only friendship. That and nothing more." We both were silent for a long time after this, for most DXers do know the feeling and the friendships. The true Internationalists of Amateur Radio are the DXers, and their bonds of friendship are far flung. Come! Join with the DXers who want naught but friendship and a new country or two once in a while.

Looking West

Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

I have always found that a trip aboard an airliner is a great time to relax and let your mind wander, to go off in search of new directions and ideas. At present I am somewhere over middle America on United Flight 5, enroute from New York's JFK International Airport back to my wife Sharon and my home in Los Angeles. More on this unplanned trip later, but for the moment join me aboard this Boeing 747 and think about a subject that is very much a part of amateur radio: tradition.

When you have been around as long as amateur radio, you are bound to develop some traditions along the way. First, though, we should ask ourselves the meaning of the word, "tradition." Since you rarely find a copy of *Webster's New World Dictionary* on a 747, I will have to trust my memory and interpret the word to mean a respect, reverence and/or following of things that have come before, a respect for a part of history. In our world of amateur radio, there has always been a lot of respect for "the state of the art," the technology and operating guidelines amateurs use to communicate more efficiently.

The traditions of amateur radio have made us a proud lot, and rightfully so. If it had not been for the early pioneers of communication (the "amateurs" who refused to quit when the rest of the world stood by laughing at their hair-brained experiments), there is a good chance the hobby/service we all love (as well as all other forms of communication like the AM radio station we listen to daily) would have never come to pass. You and I know how much amateurs have accomplished over the years and how amateur radio has benefitted all mankind.

Now, enter the VHF repeater. I have often heard it said by many a long-time amateur that repeaters and the type of operation they foster are nothing but a breakdown of the traditional operating practices that are indeed an integral part of amateur radio. I have lost count of the number of times that fellow amateurs have come to me and said that we need more of the traditional things of VHF amateur operation, such as working DX on six and two, or more utilization of the VHF bands for CW practice, and less about these "new-fangled" repeaters that are destroying amateur radio.

I have to feel sorry for these people, because they fail to realize one very important aspect of "tradition" — and that is the fact that tradition can and will change with time and that each of us individually will contribute a bit to what amateurs yet to be born will call the "tradition of amateur radio." They fail to realize that repeaters are to the 1970s what the advent of SSB was to the late 50s and early sixties, and indeed what the now ancient "rotary spark gap" was to the very foundation of amateur radio in its earliest dawning days. No, the VHF FM repeater is not and can

Caught at the June SCRA meeting is the man generally credited with being the "Father" of VHF repeaters: Art Gentry W6MEP, owner of WR6ABN (formerly K6MYK).

never be what many consider the traditional way in which amateurs should operate. The rather rigid channelization necessitated by repeater operation is to many a direct contradiction to the way that they have operated their amateur stations for many a year. It was to me, when I first got involved in this rather unique aspect of the hobby almost 12 years ago. However, rather than fighting it, I was willing to accept the challenge offered and never have regretted my decision. Even putting aside the technological knowledge I have garnered over the years, and not counting the many lifelong friends I have gathered along the way, operating a diverse number of repeaters and learning more about my fellow man has made the "trip" well worth it. For indeed, the VHF repeater has become the melting pot for people representing every aspect of both amateur radio and our society in general.

No, the VHF repeater is not "yesterday's" traditional portrait of amateur radio. It is a new aspect of our world, and along the way it is creating a lot of traditions of its own. Best of all, you and I are helping to create for the future some sound traditions, since we are a part of this "wild new breed" of amateur.

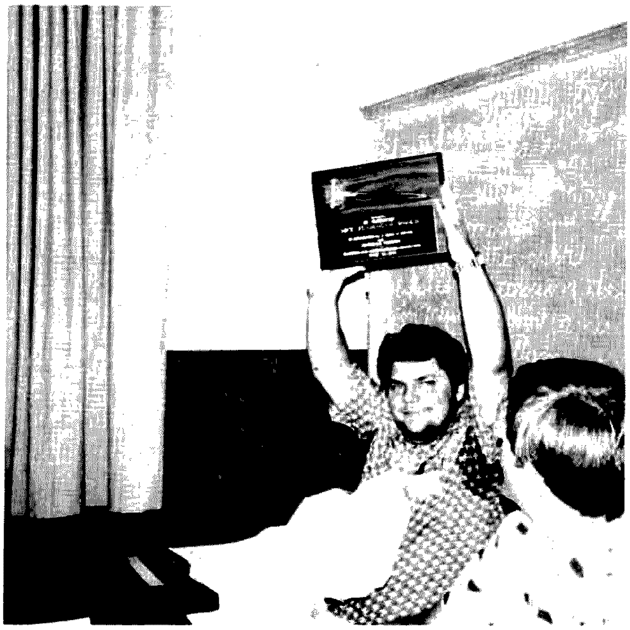
The .01-.61 problem is well on its way toward a solution, thanks to a lot of hard work by SCRA Chairman Bob Thornburg WB6JPI. As I have stated in the past, being involved as a control station for one of the two systems, namely PARC's WR6ABB, I did not feel that I should personally comment on this situation. Thanks to the SCRA, I have been spared being put in this position, since the following report to the SCRA membership by Chairman Thornburg more than details the problem, the points of responsibility in the situation and what steps the SCRA is taking to solve the problem.

SCRA
THE .01-.61 PROBLEM
STATUS REPORT
June 17, 1976
Bob Thornburg

1. By majority vote (Item 13 of the February 21 meeting), the SCRA chairman was directed to instruct WR6AFR to vacate the .01/.61 pair and resubmit for coordination on a different channel pair.
2. This motion was passed based upon the Technical Committee's report of the investigatory measurements. This report was first presented at the February meeting.
3. Examination of this report clearly showed that, indeed, interference could and did exist but:
   a) It took 200 W ERP to make .85 uV in ABB from the best (worst) site.
   b) It also showed that ABB has a 10-15 dB alligator ratio, i.e., 200 W ERP = .85 uV at ABB but ABB put 6.5 uV back at the same site.
4. Based upon reexamination of this data and
   a) at that time a strong feeling that WR6AFR would not submit to moving, and
   b) that a demand by the SCRA for them to vacate and resubmit would be ignored by AFR,

The measured data just wasn't felt to be of enough significance to convince and the interference problem would continue if this line was followed.

5. As an alternative, Bill Wood arranged a meeting with AFR to discuss the problem. On April 23, Bill Wood, Bob Thornburg, Kit and Marvel Clover, and Dick Miller met and the following came out:
   a) SCRA has in the past pointedly ignored the high desert and the attitude of the high desert people is that the SCRA did not care nor would be interested in coordinating AFR. So AFR measured many frequencies and concluded .01/.61 was the best from their site. This was before ABB put up the Micor.
   b) Now the ABB output is very strong in the high desert and required a beep/delay mode on AFR to separate the two repeaters in the high desert.
   c) Kit felt he could control his users to reduce the interference into ABB.
   d) Only if all else failed and the interference to ABB was (is) significant would he move frequencies.
   e) In Bob Thornburg's opinion, Kit is an amateur in the true sense and interested and sensitive to the interference problem. He is employed as Range Frequency Coordinator at Edwards, technically competent, and has a fine home brew repeater with most all the bells and whistles. He is also defensive of his users, but aware of their involvement in the interference problem.
   f) The following morning I attended a breakfast with about 100 of the users of AFR and, again, was impressed with their respect for Kit and the performance of AFR.
6. The SCRA Technical committee first heard of the interference to ABB in about February, 1975, and did nothing (due to other more pressing problems) until November, 1975, with



Don Root, SCRA Secretary, displays plaque awarded to ex-SCRA "Chairperson" Dick Flanagan W6OLD for his many years of service to the SCRA.

Meet the SCRA's 1976 "Mr. Chairperson" Bob Thornburg WB6JPI, as he conducts an SCRA meeting with Vice "Chairperson" Charlie Ellis K6PNM at his right.

Ed Tipler WA6KYZ, climbing antenna pole of WR6AMZ. Photo by Jim Rieger.

the Technical committee's report coming out in February, 1976. By this time, AFR was well established serving, and serving well, about 100 users in the high desert.

a) Interference does exist to ABB and don't forget it, but

b) Due to the delay in the SCRA action, and due to the SCRA's interpreted position on the high desert, I do not feel it is justified to label AFR as a renegade or pirate repeater.

7. A special meeting of the ABB repeater committee was held on May 14, 1976, for Bill Wood and myself. At this meeting, the following came out:

a) The interference to ABB from AFR users is severe and could be documented in detail if necessary.

b) PARC is possibly willing (based upon membership approval) to assist in funding a move by AFR – like sponsoring a mutual fund raising "event."

8. The information from the PARC repeater committee meeting was relayed to AFR by Bill Wood and the present position of AFR is:

a) AFR will move if it must.

b) AFR suggests maybe – possibly – please – ABB could put a NNE null in their antenna pattern. 6-10 dB is all that's needed.

c) Principal interfering base stations have been asked to reduce power toward ABB.

9. Clearly, WR6ABB has no liability or blame in causing, or continuing to cause, interference to their repeater. However, and as always, they are being "good guys" and constructively trying to resolve the problem.

10. I would like the SCRA to recognize the cooperation of both groups and provide the technical committee the following help in resolving this problem:

a) Recognize AFR as a cooperative entity by directing the Technical committee to renew AFR's testing status, valid for 90 days, with a recognized and working interference problem. Final coordination will only be issued upon resolution of the interference problem.

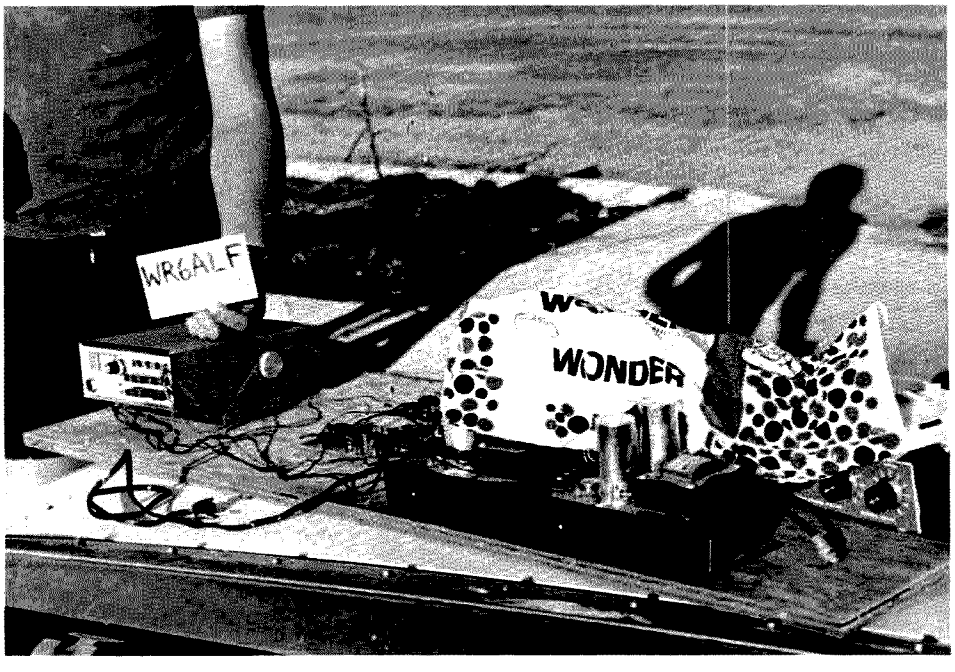
b) Remove the requirements of the SCRA motion.

While speaking about the high desert area of California, and repeater operation in that area, we are happy to introduce a new addition: WR6AMZ on Laurel Mountain, near the town of Ridgecrest, California. This system has been coordinated to and operates on a channel pair of 146.04 in, .64 out, and is co-channeled with the San Diego-based Mt. Otay system, WR6ACF. While on days that the famed Southern California inversion is "in," there does exist a bit of overlap between the coverage of the two systems; in my opinion this is a good choice, in that it permits the traveler coming from the high desert area en route to San Diego almost continuous coverage using that single channel pair. It is, I guess, also the price you have to pay when there are more repeaters than there are available channel pairs on two meters. I have a feeling that in densely populated areas such as this, with thousands of amateurs using VHF and the need for more repeaters ever on the increase, the day of the "super wide coverage, talk-to-the-world" repeater may be drawing to an end. As we grow, and as we need spectrum space for more and more repeaters, the time will come when we all may have to give up a bit and learn to share for the common good of all amateurs. But . . . we are getting off the subject at hand.

WR6AMZ is the brainchild of Ed Tipler WA6KYZ, through whose technological know-how WR6AMZ came to be. Ed is one of those super nice guys who seems to care about the amateurs around him. He decided that AMZ would be a good way to help the amateurs of his community as well as the many transients crossing the high desert equipped with two meter radios. He went forth to create his fully solid state home brew two meter system. Ed designed it so that if you could hear it, it would hear you and when you could not hear it any more, it would not hear you either . . . a "by-the-book" repeater, inversion notwithstanding. The word coming back to me from amateurs who have used it is that AMZ works like a champ and is a pleasure to operate. Come SAROC-Las Vegas time, we will have a chance to see for ourselves . . . if not sooner. AMZ may be smaller than a breadbox, but from what I have heard, it delivers. My thanks to Jim Rieger for the fine photos of the AMZ operation.

When a VHF-type amateur hears the term scatter, he usually thinks in terms of bouncing signals of the ionized tails of meteors as they burn their way through our atmosphere. Any true "traditional" VHFer will tell you that you can make some rather spectacular contacts that way, especially if you are adept at high speed CW. All this notwithstanding, when you mention "scatter" here in the southland, you are more than likely talking about a new group known as the "Southern Counties Amateur Teleprinters Society" or SCATS, with *SCATTER* being the title given to their monthly newsletter. SCATS is a new RTTY organization that sponsors an open VHF RTTY repeater, WR6ACA (146.10 in, .70 out), located atop Contractor's Point in the northeast San Fernando Valley and with coverage over a wide area of Southern California. As its newsletter, edited by Arny Gamson K6PXA, states: "The purpose of the club is firmly established on the five principals of the fundamental purpose of the amateur radio service as defined in the FCC rules and regulations. In essence: (A) Public Service; (B) Advancement of the radio state of the art; (C) Improvement of skills; (D) Expansion of operators and technicians; (E) Extension of local, national and international goodwill. The club was established for the purpose of achieving these objectives through the unique mode of telecommunications (radio teletype) and to achieve satisfaction and fun while accomplishing this."

While around for only about half a year now, SCATS is well on its way toward achieving its goals. Already they have instituted regular meetings on the second Saturday of each month, alternating between Los Angeles County and Orange County, have gotten WR6ACA totally revamped and fully operational, have set up a weekly SCATS net via ACA that



"Breadboard" system of WR6AMZ. Photo by Jim Rieger.

meets every Wednesday at 20:00 hours local time, have gotten active in amateur radio public relations, have held their first annual picnic at the ACA site, and have done a myriad of other things too numerous to mention. They are an interested, progressive group of amateurs who have found another way of serving their community through their hobby, and thereby serve the goals of amateur radio itself.

They also put out one of the most professional-looking newsletters passing through these portals monthly. I wish that you could get a look at it yourself – it is just chock full of information about happenings within the organization, as well as information about the RTTY mode itself. Unfortunately, the cost of sending out individual sample copies to every amateur requesting such would be highly prohibitive, according to my discussion with Arny; however, the club is willing to send a sample to any radio club interested in RTTY, and/or set up a "bulletin exchange" with such organizations so that knowledge can be shared by all. If your organization is into RTTY, then an SASE to Arny Gamson, Editor, *SCATTER*, 8034 Gentry Avenue, North Hollywood CA 91605, will get the ball rolling.

As I said earlier in this column, I am en route home after almost two weeks in the "Big Apple." A few quick but interesting sidelights on what I picked up in the way of "repeater happenings" while back there . . . or perhaps I should call this "what a difference 10 weeks make," since it has only been that long since I was last there.

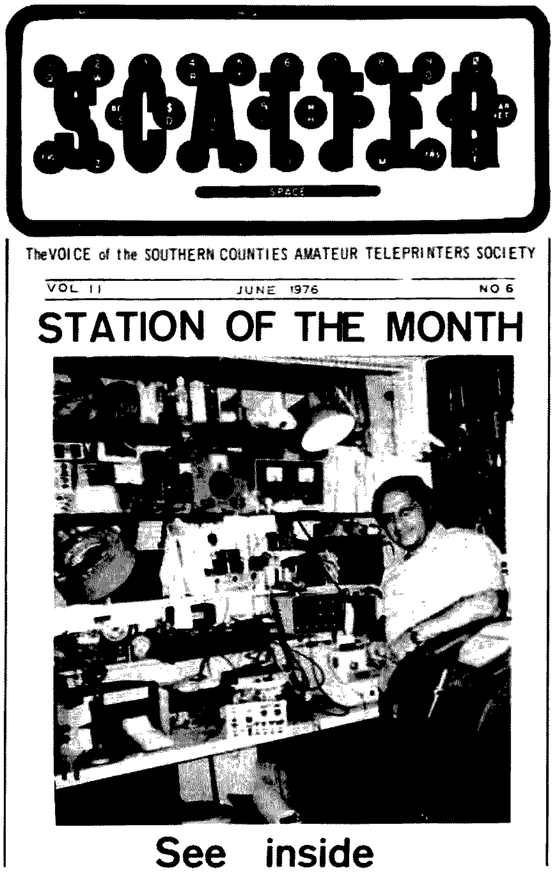
First, when I was here in late April, as usual I found WR2AAA on .13-.73. Well, that has all changed. While most of the faces . . . errr . . . voices are still the same, both the callsign and the equipment are new. According to a long-time friend Ted WA2RGB, one of those in charge of the system, the ID now says WR2ACX, the old GE Progline of the AAA days has been replaced by a shiny new VHF Engineering repeater, and a support group, the .13-.73 Repeater Association, is now in its formative stages. The machine works great, but if you plan to use it, you had better be smack on channel and have your deviation level set properly, as that receiver is razor sharp and will squelch out if your deviation level is too high. With this move, .13-.73 has gone full circle in NYC from the early days of WA2SUR, through WR2AAA, then the revamped WR2AAA on its 1 MHz channel pair of 147.73 in/146.73 out, and now to WR2ACX/2 back on .13-.73. As of this writing, ACX operates from about 6 am till 11:30 pm, but Teddy told me that as soon as a few technical improvements are made they plan to go 24 hours a day. In the meantime, much success to Teddy and crew on one heck of a good "Big City" repeater system.

Secondly, LIMARC, the Long Island Mobile Amateur Radio Club, has put on the air the New York area's first amateur television repeater. The purpose is two-fold, according to Ed Piller W2KPQ, who sort of fathered the project. First, to foster full utilization of spectrum space in order to protect the amateur service from the onslaught of other services that are after the frequencies we now use. Secondly, but equally important, is the intention of LIMARC to use this machine as a tool to interest and educate the public as to what the amateur service is all about, as well as a teaching aid in the training of new amateurs. Rather than go further at this time, I am planning an "LW Feature" on this system and its diverse uses, based on a telephone interview I did with Ed just prior to this trip. That will be coming up in a few months, so hold tight; I think you will find the concept of interest.

The Captain just announced that we will be landing at LAX in about an hour and a half, so that puts us someplace over New Mexico – probably just north of Albuquerque. With the shades pulled down so that everyone can enjoy the inflight movie, I do not want to disturb people by opening mine to look out; besides, having made this trip so many times I can just about guesstimate it. It's been a good trip home, "smooth air" all the way and, as anyone who has ever been on a 747 will tell you, rather a quiet trip as aircraft go. I only wish that the trip had been made for more pleasant reasons, but life does take its toll on us all and such was the case.

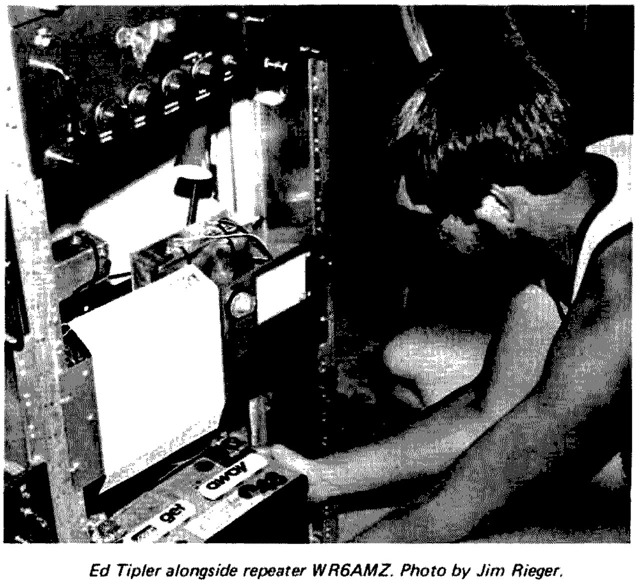
About 13 days ago my brother Bob called to tell me that our dad had entered the terminal phase of his illness and that it was time to come East. A week ago Sunday, I flew the other complement of this flight, United 8 to NYC, so that I could be with Dad for whatever the future would hold for him. The Almighty was good to him, in that he did not suffer long and passed on very peacefully at 2:30 last Monday. Bob and I were with him to the end.

I would like to take this opportunity to publicly thank the "users and management" of three New York City area repeaters, namely WR2ACX/2, WR2ACD and WR2ADM, for helping to lighten my burden a bit. It was no secret as to why I had made the trip East and anytime that I felt the need to talk, to let go a bit, there was always a fellow amateur who cared to be found just on the "other side" of my Tempo FMH. I spent many hours in QSO with some of the greatest people I have ever known, the users of the three aforementioned repeaters. While a lot of these people were old friends, many were new faces to me, many not even amateurs when I moved away from New York, many knowing me only as the voice of this column. They all had one thing in common: in the true spirit of amateur radio they cared about me and the situation I was facing. They went out of their way to try to help, to be friends to this "stranger in a strange land" sporting a 6 callsign and ending a QSO with a bunch of numbers.



There are a few people whom I must give a personal thanks to for reasons they best know themselves: to Lou K2VMR and his fantastic XYL Linda; to Larry WA2INM; to Doc WB2NDI; to Norm WB2IPQ. To all of you in the "Big Apple": What you did on my behalf will never be forgotten and you will all live in my heart and mind forever.

If all goes as planned, next month will be a rather special column. It has been announced that Commissioner John B. Johnson K3BNS will be visiting Los Angeles, and we are trying to arrange an interview with him. Will it come off? Drop by next month and find out.



Ed Tipler alongside repeater WR6AMZ. Photo by Jim Rieger.

LETTERS

BIRCHER

What is with these old-timers who hate CBers? When I was 9 years old I got my first CB radio; there were 22 people on channel 23, all of whom were 9 to 13 years old. Out of those 22 people, 18 went on to become hams; 3 now have E.E. degrees, three have first phones, and all of those 18 are in the electronics field. Without any question, CB radio was the thing that sparked them onto electronics and took them into the world of ham radio. If anyone has or knows of a young person who wants to be a ham but is not ready to take a code or theory test, send him on to CB radio. I know that it works to promote ham radio.

James W. Menefee, Jr. WA4KKY
New Albany IN

P.S. For myself, CB radio was the thing that got me going in the radio field. At the age of 23 I am the youngest station manager in the country! I also want to thank you for some of the finest editorials I have ever seen. Some of the local hams (Louisville) know that I support you, and think that I must be a John Bircher of ham radio. Keep up the good work.

KEEPING UP WITH HERB

I was quite shocked to read KL7AE's letter in the September *73*. I ordered Wilson HTs for 2m and 450 MHz on the first of June, and now 8 weeks and 3 phone calls later I still am awaiting my HTs from those Wilson "Good Guys." Who did Herb know to get such service?

Bill Fulcher W4AST/K4RTA
Hendersonville TN

BUG!

Please publish the following corrections to my "Touchtone Sequence Decoder" article published on page 52 of the June issue of your magazine: 1) missing pin number on top of the 74122 in Fig. 4 is pin 11; 2) wire from pin 12, IC1, Fig. 4 goes to pin 9 of IC1, not pin 8 as shown; and 3) in Fig. 2, the C3 symbol is reversed. The plus side must face pin 6 of the 741 if the circuit is to work properly.

C. W. Andreasen WA6JMM
Van Nuys CA

&#*$(%.!!!

I have just applied stamps to two letters. One requests a couple of tapes and some back issues of *73*, and the other a subscription to *73*. Even though I have never seen an issue before this day I am sure that I will be very satisfied. Your magazine has style. I particularly enjoyed your editorial pages. For some reason they remind me of John Campbell's editorials.

Now for some invective: @*#¢%*#¢ #&$(@*#¢ &#*$(%.!!! Why didn't someone tell me? Here I am patiently plugging away at the code on a record that I purchased in good faith, and now I find that the test will be administered at 13 wpm spaced to 5. I do not remember this fact being mentioned in any publication which I have read. In fact, I do not remember it being mentioned in either your books on General class, Advanced class, or Advanced Extra licensing. The point is, you say that it might be well for prospective hams to attempt General class immediately. I would have, had I known that little 13 wpm fact from the beginning. Now I get that sinking feeling that comes from going to Jail without passing Go. So maybe it was in your Novice book. I confess I only skimmed it, since by the time it got back to the library I had already read the General book. It would have been nice had there been some mention of the fact in the General book. It would also have been nice if there had been some mention of how one might have subscribed to *73*, along with the fact that the book is a reprint of articles from that magazine. Spilt milk.

May I say Amen to Mr. James Whitfield's comment on keyboards in your August issue. I own a Dvorak-style typewriter. Finest kind.

Finally, I hope that I will be seeing a lot of info in the coming issues on microprocessors. They are, from what I have seen, astounding.

Let me explain why they flabbergast me. One year ago, as a teacher, I attended a seminar on the new curricula for science. Along with some of the more ridiculous things which will, I fear, be foisted on our children in the future (imagine, if you will, the totally serious proposal of one curriculum that physics be taught by having the students write Japanese poetry!) was one system that would have students use an in-classroom computer. I knew nothing of computers at the time and that computer looked awfully impressive. It was as big as two suitcases. It cost better than $900.00. You needed at least two of the things to teach the class properly. It was an analog device which would, if you treated it properly, add voltages from two power supplies and display the results on an oversized voltmeter. For only $900.00. Now I find that there are digital devices available that are immensely better at a fraction of the cost . . .

Am looking forward to receiving my subscription. Keep up the good work.

Walter Norton
Nashville TN

OFF TARGET!

For the past few months I have noticed a fair number of letters on these pages from angry customers of Trigger Electronics. I would like to add my story to the long list of complaints, for the benefit of any others now facing this problem.

Last November I ordered several items for a fair amount of money and, hearing nothing after two months, I wrote them a polite letter asking about the delay. I got back a postcard saying that the goods would soon arrive. Still hearing nothing further after two more months, I called them and got the same response.

To make a very long story short, I wrote more letters and got a brush-off, after which I saw the letters in the June, '76, issue of *73* and followed some of their suggestions. I wrote to the FTC and got a polite brush-off. Then I went to the postal authorities with all the information. They immediately took it up and sent it on to the Postal Inspector, and there it has been bogged down for almost a month.

I would now like to request of anybody who has had trouble with Trigger that they, if possible, write me a letter telling me about it.

I suspect from the number of letters I have seen in *73* on this matter that there are many more who have complaints against Trigger. If enough people come forward, we could consider a class action suit against Trigger.

I hope this letter will appear in *73* and maybe help to clear up this situation.

To close this letter, I would just like to say that I enjoy this magazine and hope I do not again have need to take up space in this column for complaints.

Reading MA 01867

WHAT FUN!

I've never written a magazine before, as it takes a lot to make me write, but you have done it. Having been in CB for ten years, I know the joys of portable communication that walkie-talkies provide and the frustration caused by the lack of operation procedures by other CBers. I have been looked down on by other hams, and thought it unfair, but let it ride. None of them took the time to find out that I have an electronics background and that I knew about hams long before CB. Shortwave receivers and I have been friends for a very long time, with the ham bands capturing most of my attention and enjoyment. Then I discovered 100 mW walkie-talkies — boy, what fun! Biking, hiking, transmitter hunts and "rag chewing" with friends opened up a whole new world. Eventually I wanted more fun and more power, so I got a CB license in 1966. After a couple of years I gave up in disgust, sold all my gear, and let the license expire. In 1973, I renewed my CB license and purchased a 5 Watt walkie-talkie. Again, the fun and frustration. I told myself it was time to get my ham ticket, time to quit talking about that "someday," and do it. The code did not come easy for me, even though your "Novice" tape helped a lot. I planned on shipping right on to the General, but I couldn't seem to practice code regularly enough. I decided to take what I could get and got my Novice. After a 3½ month wait, my license came last week. Boy, what fun! I can't wait to get off work each night to get on the air. What a way to practice code! Those guys with the keys are more fun to practice with then the tapes.

Then I read your comments about deleting the Novice class! I for one will remember these Novice days with fondness. I don't consider myself a CBer gone ham — I don't like being that kind of statistic. First I am looked down on by hams for being on CB, and then I hear that to be a Novice is a waste to hamdom. Gee, I can't seem to win for losing.

Well, when I get to 14 wpm or so I am going to test for my Advanced . . . and settle for a General.

Thanks for a unique magazine that I enjoy so much.

William F. Stamps, Jr.
WN8ARZ/KWH7698
Sault Ste. Marie MI

BAD DEAL

I have a few things to get off my chest. First, I think that Docket 20777 is a bad, *bad*, deal. Docket 20777 won't hurt me, but it sure does bother me! If I ever get to 35 or 40 wpm I will feel ripped-off if I can't do it in the CW band. My first QSO, as a General, was on AM, and I didn't hear one garbage mouth. Also, AM might be almost dead, but why kill it?

I like your I/O section, even if I only fully understand the editorials. I think I am slowly but surely learning about microcomputers and, the more I understand, the more I enjoy the I/O section.

I for one enjoy CW, and in your September editorial, when you said that there wasn't a lot of CW activity,

you were wrong. The general CW band on 40 meters is very crowded at night.

I really enjoy your editorials, and I have had many pleasant experiences with your advertisers. Keep up the good work.

Penn McClatchey WB4DPT
Atlanta GA

STIMULATED

I am really interested in the computer aspects in relation to ham radio. I was getting a little bored with ham radio in general, and the computer articles and ads in your great magazine have stimulated my interest. I subscribe to about eight different radio and electronic and scientific type magazines — *73* is #1.

I also would like to comment about two of your advertisers, as many have done before me. Namely, S. D. Sales and James Electronics. Their *service* and prices can't be beat. They will have all my business.

Jack Ehrlich WA6ASQ
Eureka CA

ANGOLA ANGUISH

I have just returned from a two week tour of duty in Luanda, Angola. The company I work for has a contract with the government of Angola to install some communications equipment. I was over there checking out several of the transmitters to be used in the system.

While I was there, I was told about the following incident. Near our warehouse on the outskirts of Luanda is the site of a very interesting ham station. This station had the most beautiful dish and helix antennas you would want to see. The chap who had spent his whole life building up this fine station was CR6CH, Sr. Carlos M. Bettencourt. Well, when the change in government came to pass recently the Cubans came in and stole all his equipment they could cart off. The dish and helix antenna are still there, but that is about all. Then about three weeks ago "bandits" broke into his house and murdered him. That is the "official" explanation. No one believes that story, though. As far as I was able to determine, there are no hams active in Angola legally at this time. The country designation has been changed from a CR6 to D2 . . . but no hams could I find. I don't blame them, considering "bandits" on the loose!

So much for Angola. Now that I have returned home from that long trip I plan to get at it again and do some more experimenting with my microcomputer and put it on the air with my station. Will write up my experiments and send them to you for possible publication . . . back to the workbench . . .

Louis I. Hutton K7YZZ
Bellevue WA

QUALITY

Enclosed is a check in the amount of $10.00 for a 1 year subscription to *73 Magazine*. While I have little active interest in the hobby of amateur radio, I find your new computer columns and articles to be of excellent quality and contain more good technical information than is available from any other source — not to mention the best selection of computer equipment advertisements of any magazine around.

Robert H. Lyons
Lansing MI

BUG II

Please note the following corrections to my article, "500 MHz Scaler" (October, 1976, page 62): 1) the CE output of the 11C90 is at pin 1, while that for MS is at pin 14; and 2) the unlabeled capacitor on the component layout should have a value of 10.

Peter Stark K2OAW
Mt. Kisco NY

KENSCO CARES

Thought I would write you and tell you about one of your advertisers, Kensco Comm. of Quincy, Mass.

I had bought 2 sets of xtals from them and used them on my mobile and home 2 meter rig. Then the guys who own one of the local repeaters, because of some 3rd order intermod, decided to change frequency. I figured I was out $20 for the 4 xtals, having none for the new frequency. So I write to Kensco and they came back with a very interesting policy: "If you bought xtals from them, you can exchange them with Kensco for any other ones you may want at no charge."

How about that for a policy? If Kensco would allow you to mention this policy in your magazine, it would be giving the ham who buys from them a break.

Jim Dates W2QLI
Corning NY

BUG III

Just returned from an extended vacation (cum job-hunting expedition) and, after sorting through about 10 pounds of mail, I came across a letter (read plea for help) from Bob Brown WA6ZKI in Long Beach, California. The poor guy read my article on the soldering iron holder in the July issue of *73* and decided it was just what he needed, so he built it exactly as shown and wired it in accordance with the published diagram. To make a long tale even longer, it didn't work right and he couldn't figure out why. I dug out the original copy and checked my pencil drawn diagram against the one on page 18, and, lo and behold, there is a small but oh-so-significant typo. The original shows a connection between the lead from SW3 and 4 to the lead from SW1 and the green pilot light to D1. There should have been a connection dot where those lines cross — and there ain't no such animal. No wonder the poor guy couldn't get it working right. I sent him a correction and hope that you can publish one also, before too many guys think that this is just another cloonge article.

Arny Cain WB4FDQ
Melbourne FL

CAPITOL QSOs

With interest I read your editorial on page 4 of the July, 1976, *73*, a portion of which concerned the use — or nonuse — of bicentennial callsigns. Certainly it is in the great American tradition of freedom that each individual amateur operator is allowed to independently decide whether or not to use the optional identification. Your readers may be interested to learn that we at the Capitol Hill Amateur Radio Society confirm AC3USS QSOs with a special three color QSL.

The card depicts the "East Front of the Capitol of the United States as originally designed by William Thornton — and adopted by General Washington — President of the United States." It looks quite different today, having been added to and modified several times. Visitors to the Capitol may view a history of the Capitol's physical evolution in the "crypt." The drawing reproduced on our QSL card is in this exhibit.

There is quite a history behind Dr. Thornton, the Capitol's architect (today the architect of the Capitol — an appointive office — oversees the structural and mechanical care of the Capitol and associated buildings and grounds). Thornton was a medical doctor and inventor whose major amateur architectural project seems to have been designing our Capitol building. Even though he missed the deadline for the design competition, his drawings were accepted. Both George Washington and Thomas Jefferson liked his plans and he won. His prize? Five hundred dollars and a lot in the then brand-new (and quite muddy) City of Washington.

AC3USS operates from the Senate Office Building on the Capitol grounds. Over one half of the Senators and many committees have their offices in the same building (and are thus susceptible to our RFI). The station is entirely financed from the private funds of members and began operation in 1969. It was, according to the Capitol Hill Historical Society, the first recorded amateur radio station operated from the legislative branch of government. Up to one kilowatt of power is used on 160-10 and 2 meters to contact hams around the nation and around the world from this historic landmark and institution.

David R. Siddall WA1FEO
Washington DC

RAMSEY RECOMMENDED

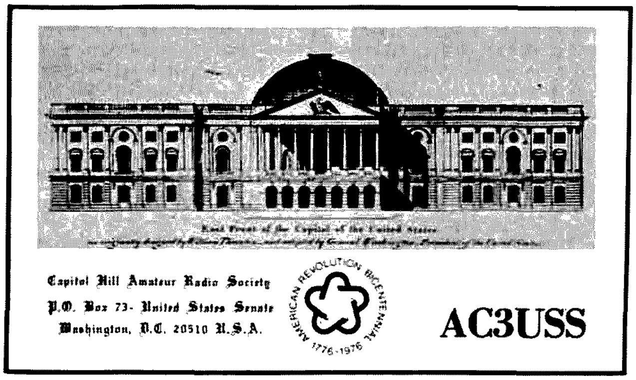
Kudos for Ramsey Electronics of Rochester NY, an advertiser in *73*. John Ramsey and his wife were exhibitors at the ARRL Atlantic Division Convention in Philadelphia on July 23-25. I purchased a fantastic little 6-LED clock which didn't work due to a couple of solder bridges I had added but didn't find. John straightened the problem out in a couple of minutes at no charge. Very friendly and personable with all who came to his booth. I'm sure the firm will do quite well and I recommend Ramsey Electronics without reservation.

Thomas R. Sundstrom WB2AYA
Willingboro NJ

1000%

I just wrote to say again keep up the good work. Your magazine gets better all the time. One thing I miss is the Solid State column by Waller Scott. It had lots of interesting things in it. I enjoyed it because it kept me up-to-date on new transistors. Please bring it back. Also, I miss the repeater updates that you had so often.

As you always say, the *73* code tapes are really great. I know in our area they are used to train many Novices and people that want to update for a higher class. Several people that got the *73* tapes said that they never knew how easy it is to



learn the code. Learn it at 13 wpm once and be done with the hump and all the frustrations that go with it.

I believe that you are doing the ham radio fraternity a great service by selling these tapes at such a low price. I know that they have helped many new hams get started. They really are revolutionary in their methods and speed of learning for the student.

Keep fighting Ma Bell, too. She rips us all off! I don't know what she did to *Telephone Electronics Line*, but the magazine must have gone under because I get no more copies and have written them several times with no reply. I did get a notice from Pacific Bell sent to all subscribers not to use any information in the magazines. I don't know what gives Ma Bell or anybody else the right to censor the press so it can't print information on it, but if it can, then we are ruled by the big corporations.

We need more men like you, Wayne, to wake people up before it is too late and we are no longer free. I know we are not free now, but slowly but surely 1984 will really be with us with Big Brother at the controls and us just puppets.

Keep fighting the ARRL too, because they are against progress (or so it seems to me), and let's get some new blood in the ham ranks that will stand up to get more frequencies for our bands. We could sure use them, as many of them lie fallow. Used only by the government occasionally. We could put them to better use!

I am with you 1000%, Wayne. Keep *73*'s high standards up there.

Pete Hons W3PKH
Portage PA

WATCHING BELLE

Student amateur radio operators, members of Maple Hill High School's Amateur Radio Club, WB2YCR, stood hurricane watch at their home stations during Hurricane Belle's recent visit to our area. Alerted by telephone, each student monitored special emergency net frequencies on receivers at their home stations. On these nets, the students learned by listening to actual emergency net procedures, information bulletins on damage and evacuations, and "traffic" or message-handling techniques. Most of the student operators listened to the Red Cross Emergency East Coast Net run by station W1KBN in Boston. Others monitored state nets in New Jersey, Pennsylvania, Delaware, Connecticut, Massachusetts, New York, and New Hampshire.

Students also copied detailed information on the storm's progress from station WWV, run by the National Bureau of Standards. These bulletins gave the storm center's location in longitude and latitude, its wind speed, direction of movement, and other vital data. Using skills learned in Geography class and maps from local gas stations, they plotted the storm's progress from Cape Hatteras into New England. In this way, they were able to utilize their home stations, their radio skills, and their geographic knowledge in a useful and exciting way.

John Kienzle WA2UON
Castleton NY

OFF TARGET II

As a subscriber to your fine magazine, I've seen your comments on Trigger Electronics.

I recently received my Novice license and, with it, a batch of advertisements with mailing labels distributed (sold?) by the FCC. One such advertisement was from Trigger Electronics, a catalog. The catalog was full of such bargains, that, forewarned by letters in *73*, I took a second look. What I found was a catalog printed in 1973. It was mailed to me in June, 1976.

I wish to bring this to your attention and, hopefully, keep some new ham from making a bad mistake.

Thomas G. Vavra WN8ZRL
Fairborn OH

THE CAUSE OF IT ALL

Well, you're the cause of it all! Your I/O articles got me hooked on this computer business, and now I'm knee deep in it. I've been going to a microcomputer class given by the "Byte Shop" here in Santa Clara, and, besides learning a lot, I've found that most computer hobbyists aren't all that familiar with ham radio and *73 Magazine* in particular. There is a definite crossover point in the technology, and the two fields certainly complement each other. Take, for instance, the use of ham AFSK tones for digital data recording vs. the KC standard (with all due respect to your trip to Kansas City). The baud rate using our standard tones can be much faster than the KC standard. The point is, the technologies cross, and systems that we consider "run of the mill" can be a godsend to computerists. I've done my bit as far as informing the local group as to what *73* has to offer, but there must be some way to let the computer hobbyist audience know the advantages ham radio has to offer.

Your idea of making cassette tapes available with computer programs is outstanding. My entrance into the computer field was via MOS Technology's KIM-1 CPU board. One of the main reasons I purchased this board was the on-board cassette interface. KIM-1 does not use the KC standard, but it is an excellent interface system and may be recorded on normal cassettes. This could be a starting point for your software distribution system, and I'd really like to see this happen. A gentleman in San Jose is just finishing a 2K Tiny BASIC for KIM, and I'll contact him when he's finished to let him know about your distribution, royalties, etc. I'd like to see a good software distribution for KIM, since the 6502 is a really nice CPU.

Bob Grater K6SUB
Santa Clara CA

DOWN TO REAL GOOD

How about some articles for the ham that do not have anything about them except that they are expensive?

Super great magazine, except for those I/O articles – they cut it down to real good.

Well, 73, and thanks for the good magazine.

Curtis Junck WBØJYF/6
Fair Oaks CA

BUG IV

Concerning the article on the "TT Pad for the Wilson HT," July, 1976, I have found that the part number given for the Motorola belt clip is the number stamped into the plastic, but the parts catalog lists this part as #1-84206D81 and sells for $3.50. I ordered mine through the local Motorola shop and, sure enough, this was the number on the plastic bag the part came in. Hope this info helps those who want a good belt clip for their HT.

Harold C. Hageman WA5FCV
El Paso TX

REJECTION REJECTED

I rejected *73* earlier this year, as I subscribed to *QST* and *HR*. Last week I borrowed a copy of your June issue from K4FTY and realized I should have subscribed.

Huntsville AL

HATS OFF

Listening to WB4GLG in Kentucky working on the hurricane watch net was not only refreshing but truly exhilarating. Being a 4 year vet of CB and seeing how "good buddies" spend most of their time arguing about whose "channel" it is and whose mike is splattering who, it was good to hear him (and the countless others) really putting their all into helping those in need.

I myself have to say "hats off" to those involved in the net helping others. And to the few idiots on the band – may the short circuits of a thousand Hurricane "Belles" invade their shacks, along with the FCC with their axe.

I am working to get my Novice, then General, ticket in the near future (January, hopefully), the Good Lord and FCC willing. Looking forward to talking to all of the great people in the world of radio and handing them the respect they very much deserve.

John P. Keefe
Waterford NY

P.S. My first issue of *73* was the September, 1976, one. That is where I read of the net and found out about it. It will become #1 in my magazine library, as I won't miss any coming issues. Just got started with a 101-B – a few kft of wire. Who said all CBers were clowns?

BLESS TRUCKERS

I find it amusing to read letters that you have printed, written by hams, that castigate you for advertising CB radio and advocating recruiting future amateur operators from the ranks of CB operators. Personally, I agree with your stand on the subject. CB has grown up quite a bit since the fuel crunch and the advent of the 55 mph speed limit. CB radio has its place in the overall scheme of communications.

For instance, when I travel, I have a CB, a 2m amateur FM rig, and my "company" radio in the car. I work for a large governmental public safety communications agency, and thus have the 24-hour-per-day services of a public safety dispatcher available at the push of a mike button. And, since our agency uses multiple high level repeaters, I can contact the office over much of central California.

Most hams wouldn't scoff if I happened to report some sort of emergency over the company radio, yet these same hams would look at me funny if I reported this same emergency to the West Dismal Seepage REACT on channel 9. They also would probably think that familiarity with the 10-code on a public safety frequency is the mark of the professional, but if I should use that same radio code on CB I would be branded a nerd – or worse.

CB radio lets me talk to my lady legally, without her having to become technically oriented or take any test. When we visit her family on the north California coast, CB is virtually the only communications we have. There are few hams up there on 2 meters, but there are plenty of CBers.

On the highway, my little 11 meter rig has paid for itself over the past year by helping me avoid speeding tickets with their attendant fines, not to mention the insurance premium increases. When the speaker spats out, "Break for that Southbound, you got a Smokey on your back door," it's just natural to back down to "double nickels." Bless the truckers. They have set up a really efficient communications system.

The CBers I've met on the road are, for the most part, every bit as friendly as the hams I ran into fifteen years ago when the ink was still moist on my new license and I hesitated before entering a club meeting of electronic

supermen. The Marin Amateur Radio Club of Novato treated me wonderfully and made me feel at home, even though I had a Technician license and couldn't operate on the "club" frequency of 3885 kHz. They encouraged me to write a VHF column for the club paper, and to set up the VHF stations for field day. I felt appreciated, and it was great. If ham clubs made newcomers feel at home, welcome, and "proud to have ya here, Podner (with a capital P)," I feel that the ranks of amateur radio would swell visibly. People are insecure in strange surroundings, and a neophyte ensnarled in a snobbish ham club meeting will probably leave, disillusioned, and take up photography, sky diving, or some such. If I had been treated discourteously during my early days as a ham, I never would have pursued the hobby. I feel that most folks feel the same way. No one enjoys being made to feel stupid or inadequate.

Another thing to remember: A CBer (or other person who has not been initiated into the world of electronics) can *never* ask a stupid technical question. Be patient. If they knew as much as you do, they'd have a ham ticket. But they're just starting out, just as you and I did many years ago. They don't have the amateur license or skills, or a commercial radiotelephone license. CBers appreciate patient, detailed, simple answers to their queries. Don't try to snow them with your great knowledge — *help* them with it. Be sure that they understand what you are telling and showing them. While you're at it, show them amateur radio, and how easy it really is to get started. Chances are, you'll have a new recruit for the amateur ranks. But if you ridicule him, and make him feel so low that a snake wouldn't have to step high to get over him, don't expect him to be enthusiastic about getting into amateur radio. No man goes readily where he feels outcast before he begins.

Thanks for taking the time to read this letter. You have my permission to line the bottom of the birdcage with it.

I am enclosing a check to cover the cost of the 14 wpm code cassette and the Advanced Class license study manual. After 15 years as a Technician licensee, I have decided to go for the biggee. And, as a lifetime 'scriber, let me add, Keep It Coming. Your publication is the best I've seen in the field.

Alan Christian WA6YOB
San Jose CA

BUG V

I have found an error in my article in *73*, April, 1976, p. 55, "One IC Tone Burster." Here's the change.

The emitter and base of the NPN xstr are switched; the amp is common *base*, not common *emitter*.

Lhary Meyer WB6ZMA
Fairfax CA

ATLAS ANSWERS

A little experience you might get a kick out of happened just recently. I got a great buy on an Atlas 210x from a dealer who picked it up from a CB dealer on a bad debt. Lo and behold, it had on the dial and on the freqs the 11 meter band all marked out as pretty as can be. And, of course, with 200 Watt input.

A letter to Atlas complaining about this setup brought a quick telephone call from the California firm with the information they did not put this rig out in that condition and they had encountered this before. They kindly sent me a new dial and a little tweaking brought it back on 10 meters. Incidentally, that is one helluva rig and every mobile HFer should have one.

Angola IN

OFF TARGET III

Concerning "Another Shooting Victim" and Trigger Electronics, River Forest, Illinois:

My advice to all the amateurs out there who are waiting and waiting is that a few complaints to the postal authorities will straighten out Mister Trigger pretty quick. The Post Office is very eager to go after people like that.

The August issue of *73* is the first one for me and it looks like a very interesting magazine. I'm sure I will enjoy it for many years to come.

Gerald Greenwood WB9SWA
Chicago IL

MISSED

Hermann Kortbus WA2LWK was killed today in a car accident. Many hams will miss his schedules, help and friendliness. Hermann had his 60 ft tower and 4 el quad ready to put up, but he never got to it.

Kurt Bittmann WB2YVY
Centereach NY

SHOCKED

September '76 *73 Magazine* arrived today. I am shocked to learn that FCC Docket 20777 is so restricting, especially since "de-regulation" is supposed to be the FCC's new motto.

It seems to be another case of a government bureau pushing the citizens around — like auto seat/strangle belts and inflatable cushions — motorbike helmets — father-son/mother-daughter banquets, and so on — including confiscatory taxes.

Your comment in "Never Say Die" regarding opening up the bands: Any mode anywhere sounds excellent and makes good horse sense. The bureaucrats and the ARRL will hate you and villify you for it, but I love you for it.

Paul L. Schmidt W9IDP
Bloomfield IN

U-HUM

It seems that every simple QRP rig is meant for 40 meters. I wish someone would design a simple transmitter (with a complete parts list) for the 15 or 10 meter Novice bands.

The only thing I have against 40 meters is all those u-hum foreign stations. It's almost impossible to find a section of the band that's clear.

Whoever had the idea of combining broadcasting and amateur stations is off his or her rocker!

I'm 14 years old, and am waiting for my Novice test to arrive.

John Halliwell
Hampton TN

P.S. This letter was inspired by your editorial in the July issue of *73*. I hope it meets your standards of complaining.

ANTI-73?

Having been a member of the ARRL for two years, I was never exposed to the "other side" of ham radio — that is, until a friend gave me a couple of back issues of *73*.

Now a subscriber, I find *73* an entertaining as well as useful magazine. However, I have a few suggestions which I think would make a good thing better. First (and most annoying), is the fact that you rarely (if ever) publish an anti-*73* letter in your "Letters" column (and don't tell me there aren't any!). Even *QST* has one or two anti-ARRL letters in their correspondence column — even though they obviously disagree. Sincere negative criticism is a useful tool — and should be voiced.

Another problem is one you rightly accused *QST* of — too technically-oriented copy. Lately, *73* has more closely resembled an RCA TTL manual than a ham magazine — how about some basic projects?

One thing which I was at first opposed to, but later very much pleased with, is the I/O section. Although some articles are out of my reach, *73* has effectively introduced me to microprocessors which I soon hope to become involved in.

Another advantage of *73* over *QST* is *73*'s lack of dull columns of call letters, contest results, "News and Views," etc. *QST* wastes half an issue each month on this. Ugghh!!

As far as *QST* goes, I find it a worthwhile magazine because it gives current news, has some basic and practical articles each month, has want ads, and is published by the ARRL, which, although it is not the best organization and is not totally agreeable with my views, is still worthy of my support.

So, all in all, I think I speak for at least a few hams when I say *73* and *QST* are both good and worthwhile magazines, and contribute to the safe growth and support of our hobby.

Brian Rackham WA7ZHJ
Scottsdale AZ

P.S. Notice how I didn't even bring up the fact that *73* has published CB ads (a commercial sellout?) and *QST* hasn't. And notice how I didn't mention how, as you stated, "informing CBers is our duty as hams." I didn't say, "no, it isn't — it is our duty to convert CBers to ham radio?" Don't worry, I won't say it.

Well, Brian, I've been reading QST *for over 40 years now . . . it's okay. Regarding anti-*73 *letters . . . yes, we got one last month . . . it wasn't very interesting. — Wayne.*

OFF TARGET IV

Just a quick note to tell you guys what a great magazine you put out.

Now that I've got your attention, I also want to complain about Trigger Electronics. 7 weeks ago I ordered two measly Novice band crystals for $6.30. According to my canceled check, they cashed it 3 days later and I haven't heard from them since. After phone calls and letter writing, I finally had to go to the Better Business Bureau. It would have been quicker to have my local supplier back order it from the factory. Fine way for a new Novice to start out — shining new equipment and no crystals. Oh, well.

Keith Payea WN1WWX
Fitzwilliam NH

STUCK UP

I am glad to see all of the ham magazines finally covering the CB scene. I cannot say that I am in total favor of CB, but I see the need for it and understand the reason for its popularity.

I have had a CB license since 1961, obtaining my amateur license in 1965 and FCC Commercial license in 1968. I will not in any way have a CB rig in my house, but on the other hand I go nowhere in my auto without one.

On a recent 5028 mile trip from the west coast back east and back through the northwest, I became more convinced that the majority of hams are stuck up. I met very helpful hams in all states, especially Denver, Salt Lake, Oklahoma City and Phoenix. However, in general they wouldn't even talk. In many cases, QSOs on a repeater would stop, and then several minutes later I would hear, "Well, guess that 'nut' is gone — now we can continue." The number of closed repeaters is amazing.

On the other hand, I never met an unfriendly CBer. Some rough language many times, but at least an answer.

Also, there is always someone mon-

CONTESTS

IARS/CHC, FHC, SWL-CHC, HTH QSO PARTY

Starts: 2300 GMT Friday, November 5
Ends: 0000 GMT Monday, November 8

An SASE to K6BX will bring more detailed information. Contest is open to all amateurs and SWLs worldwide. Same station may be worked on each band and mode; SSB and AM are different modes.

EXCHANGE:

QSO Nr., RS(T), name, CHC/FHC Nr., US state and county or similar division. Non-members send "HTH" instead of CHC/FHC nr.

SCORING:

For CHC – 1 point per QSO with other CHCers, 2 points if HTHer, and 1 additional point if YL, B/P, FHC, Novice, CHC-200, Merit or Club station, or if on VHF/UHF. Double above points if QSO is out of own country. For HTH – contacts with other HTHers count 1 point, with CHCers count 3 points. Rest same as above. For SWL – use same as above depending on whether CHC or not.

MULTIPLIERS:

Each different continent, country, ITU zone and US state (counted only once).

FINAL SCORE:

Multiplier times total points is final score. Multi-operator stations divide score by number of operators.

FREQUENCIES (for US and DX as allowed):

CW: 3575, 3710, 7070, 7125, 14075, 21075, 21090, 21140, 28090, 28125.

Phone: 3770, 3775, 3790, 3943, 3960, 7070, 7210, 7260, 7275, 14320, 14340, 21360, 21440, 28620, 50.1-50.5, 145-147.

AWARDS:

Hundreds of certificates and trophies in all categories and divisions are awarded. An SASE will bring further information. Send all requests and logs to: International Amateur Radio Society K6BX, PO Box 385, Bonita CA 92002. Logs should be mailed within 15 days after the close of the QSO Party.

RSGB 7 MHz DX CONTEST
Phone

Starts: 1800 GMT Saturday, November 6
Ends: 1800 GMT Sunday, November 7

EXCHANGE:

Report and serial number, starting with 001.

SCORING:

Non-British Isles stations score 5 points for each contact with the British Isles; those outside Europe score 50 points. All may claim a bonus of 20 points for each British Isles numerical prefix worked (G, GC, GD, GI, GM, GW – 2, 3, 4, 5, 6). Contacts with stations using GB prefixes will not count for bonus points.

AWARDS:

Non-European stations must make at least 10 QSOs to qualify for an award.

LOGS:

Logs and entries must be addressed to the HF Contests Committee, c/o J. Bazley G3HCT, Brooklands, Ullenhall, Solihull, West Midlands, England, to arrive no later than December 29th.

CALENDAR

Nov 5 - 8	IARS/CHC/FHC/HTH QSO Party
Nov 6 - 7	RSGB 7 MHz Contest – SSB
Nov 6 - 8	ARRL Sweepstakes – CW
Nov 9 - 10*	YL Anniversary Party – Phone
Nov 13 - 14	European DX Contest – RTTY
Nov 13 - 14	Delaware QSO Party
Nov 13 - 14	Missouri QSO Party
Nov 14	International OK DX Contest
Nov 20 - 22	ARRL Sweepstakes – Phone
Nov 20 - 21	All Austrian Contest
Nov 27	10 Meter Ground Wave Contest
Nov 27 - 28	CQ Worldwide DX Contest – CW
Dec 4 - 5	ARRL 160 Meter Contest
Dec 4 - 5	TAC Contest
Dec 11 - 12	ARRL 10 Meter Contest
Dec 31	Straight Key Night
Feb 19 - 20	YLRL YL-OM Contest – Phone
Mar 5 - 6	YLRL YL-OM Contest – CW

ARRL SWEEPSTAKES
CW

Starts: 2100 GMT Saturday, November 6
Ends: 0300 GMT Sunday, November 8

Phone

Starts: 2100 GMT Saturday, November 20
Ends: 0300 GMT Sunday, November 22

Sweepstakes is sponsored by the ARRL and is open to all amateurs in the US, US possessions, and Canada. No more than 24 hours of operation are permitted during the 30 hour contest period. Time spent listening counts as operating time and OFF periods may not be less than 15 minutes. Times on and off as well as QSO times must be entered in the log. Each station may be worked only once, regardless of band.

CLASSES:

All entries will be classified as either single or multiple operator stations. Single operator stations will be further classified by input power: Class A = 200 Watts dc or less, Class B = above 200 Watts. All ARRL affiliated clubs may also participate in the club competition.

EXCHANGE:

Number, precedence, your call, CK and ARRL section. Send A for precedence if power is 200 Watts dc or less, otherwise send B. For CK, send the last 2 digits of the year you were first licensed.

SCORING:

Score 2 points for each completed QSO. Final score is sum of QSO points multiplied by the total number of ARRL sections plus VE8 (max. 75).

AWARDS:

Certificates will be awarded to the highest scoring Class A entry and the highest scoring Class B entry in each section, provided there are at least 3 single operator entries or the score is 10,000 points or more. Certificates will also be awarded for high scoring Novices and Technicians. Multi-operator entries are not eligible for certificate awards and will be listed separately in the results.

FORMS:

It is suggested that contest forms be obtained from ARRL, 225 Main St., Newington CT 06111. All entries with 200 or more QSOs must have a cross-check sheet to check for duplicate QSOs. Each log must show date, QSO time, times on/off, exchanges sent and received, band and mode.

Note: These rules were taken from last year's contest.

EUROPEAN DX CONTEST
RTTY

Starts: 0000 GMT Saturday, November 13
Ends: 2400 GMT Sunday, November 14

Rules for the contest are the same as for the Phone section, with one exception: In the RTTY section, contacts with one's own continent are permitted and count 1 point per QSO. Multipliers will be counted as before.

Complete rules appeared in the August issue on page 11. Briefly, the basic rules are as follows:

Use all bands 3.5 through 28 MHz, with only 36 hours of operation out of the 48 hour contest period for single operator stations. The 12 hour rest period may be taken in up to 3 periods. Classes include single operator (all band), and multi-operator with single transmitter.

EXCHANGE:

RST and progressive QSO number starting with 001.

SCORING:

Each QSO will count 1 point. A station may be worked once per band. Each QTC (given or received) counts 1 point – see August issue. The multiplier for non-European stations is the number of European countries worked on each band. Europeans will use the ARRL countries list. In addition, each call area in the following countries will be considered a multiplier: JA, PY, VE, VO, VK, W/K, ZL, ZS, UA9/UAØ. The multiplier on 3.5 MHz may be multiplied by 4; the multiplier on 7 MHz may be multiplied by 3; the multiplier on 14/21/28 MHz may be multiplied by 2. The final score is the total QSO points plus QTC points, multiplied by the sum total multipliers from all bands.

AWARDS:

Certificates to highest scorer in each country, reasonable score provided. Continental leaders will be honored. Certificates will also be given to stations with at least half the score of the continental leader.

LOGS:

Use a separate log sheet for each band. Logs for the RTTY section should be mailed no later than December 1st. North American stations may send their contest logs to: H. E. Weiss WA3KWD, 762 Church St., Millersburg PA 17061, USA. All others should send their logs to: WAEDC – Committee, D-895 Kaufbeuren, Postbox 262, Germany.

DELAWARE QSO PARTY

Contest periods:
0001 to 0600 GMT & 1600 to 2200 GMT November 13
0001 to 0600 GMT & 1600 to 2200 GMT November 14

This year's Delaware QSO party is sponsored by the Delaware Amateur Radio Club, W3SL. Stations may be worked once per band, per mode for QSO points.

EXCHANGE:

Delaware stations will send QSO number, RS(T), and county. All others send RS(T), ARRL section, or country.

FREQUENCIES:

CW: 3560, 7060, 14060, 21060, 28160.

Phone: 3975, 7275, 14325, 21425, 28650.

Novice: 3710, 7120, 21120, 28160.

SCORING:

Delaware stations score 1 point per QSO multiplied by the total number of sections and countries worked. Outside Delaware score 5 points per DEL QSO times 1 for one county worked, 3 for two counties worked, or 5 for all three DEL counties worked (DEL counties = Kent, New Castle, and Sussex).

ENTRIES AND AWARDS:

Appropriate awards will be given along with a certificate for working all three DEL counties. Mailing deadline is Dec. 31, 1976. Send logs to John Low K3YHR, 11 Scottfield Dr., Newark DE 19713. Include an SASE for results or the W-DEL award.

MISSOURI QSO PARTY

Starts: 1800 GMT Saturday, November 13
Ends: 2300 GMT Sunday, November 14

The 13th annual QSO party is sponsored by the St. Louis Amateur Radio Club in an effort to activate some of the hard to get Missouri counties. The same station may be worked once per band and mode. Missouri mobiles will count separate from each different county.

EXCHANGE:

QSO Number, RS(T), and QTH; county for MO stations; state, province, or country for others. MO mobiles start with #1 from each county activated.

FREQUENCIES:

3540, 3910, 7040, 7240, 14040, 14280, 21110, 21360, 28110, 28600, 50-50.5.

SCORING:

Score 1 point per QSO; MO stations multiply contact points times number of states, provinces, and countries; others multiply by number of MO counties (115 max). MO mobiles total separate score from each county activated.

AWARDS:

Certificates to top scores in each state, province, country, top 10 MO entries and top 3 MO mobiles.

ENTRIES:

Mailing deadline for logs is December 15th. Address all entries to: St. Louis ARC – KØLIR, 842 Tuxedo Blvd., Webster Groves MO 63119. Include an SASE for results.

INTERNATIONAL OK DX CONTEST

Starts: 0000 GMT Sunday, November 14
Ends: 2400 GMT Sunday, November 14

The participating stations work stations of other countries according to the official DXCC Countries List. Contacts between stations of the same country count only as a multiplier, but Ø points. All bands from 160 to 10 meters, CW and phone may be used. (OK stations are only licensed to operate CW on 160 meters.) Crossband as well as cross-mode contacts are not valid.

EXCHANGE:

Exchanges consist of a 4 or 5 digit number indicating the RS(T) and ITU zone.

SCORING:

A station may be worked once only on each band. A complete exchange of codes counts one point, but three points for a complete contact with a Czechoslovak station (except as noted above for stations in the same country). The multiplier is the sum of the ITU zones from all bands. Final score is then the sum total of contact points times the multiplier.

CATEGORIES:

A – single operator, all bands; B – single operator, one band; C – multioperator, all bands. Any station operated by a single person obtaining assistance, such as in keeping the log, monitoring other bands, tuning the transmitter, etc., is considered as a multi-operator station. Club stations may work in category C only.

AWARDS:

A performance list of participants will be worked out by the contest committee for each country. A certificate will be awarded to the top scoring operators in each country and each category. The "100 OK" award may be issued to stations for contacts with 100 Czechoslovak stations, and the "S6S" award (and/or endorsements for individual bands) may be issued to a station for the contacts with all continents. Both awards will be issued upon a written application in the log. No QSL cards are required for either award.

LOGS:

A separate log must be kept for each band, and must contain date and time in GMT, station worked, exchange sent and received, points (Ø, 1 or 3), and ITU zone (with the first QSO for that zone only). The log must contain in its heading the category of the station (A, B or C), name and callsign, address and band or bands. Also, indicate the sum of contacts, QSO points, multipliers and the total score of the participating station. Each log must be accompanied by the following declaration:

I hereby state that my station was operated in accordance with the rules of the contest as well as all regulations established for amateur radio in my country, and that my report is correct and true to the best of my belief.

Logs must be sent to The Central Radio Club, Post Box 69, Prague 1, Czechoslovakia – postmarked no later than December 31, 1976. A list and map of ITU zones is available for 2 IRCs from the same address.

ALL AUSTRIAN CONTEST

Starts: 1900 GMT November 20
Ends: 0600 GMT November 21

RESULTS

RESULTS OF 1975 TOPS CW CONTEST

The top 10 scorers of a field of 173 are shown below. It is interesting to note that W1SWX was the only US station listed anywhere in the results – he finished 6th.

G3FXB	111,500	W1SWX	63,712
LZ1SS	107,863	YU3TJA	62,315
HA9RU	79,461	DL1BU	61,152
XN1KE	72,874	OH1LA	53,912
OK2BPO	71,295	DM3YBF	50,687

The contest is open to all amateurs; power input must be in accordance with licensing regulations. All contacts must be on 160 meters, on CW only. Foreign stations use the call "CQ OE," Austrian stations will use the call "CQ TEST." The authorized suballocations for Austria are: 1.823-1.838, 1.854-1.873, 1.873-1.900 MHz.

EXCHANGE:

RST and QSO number starting with 001. Each exchange must be confirmed by repeating the exchange code.

SCORING:

Every completely logged QSO (date, time in GMT, frequency in MHz, call of station, exchanges given and received) counts one point. Multipliers are 2 points for every Austrian "Bundesland" (OE 1 – 9), and one point for every prefix. Multiply QSO points times multipliers for final score. Every station can be contacted only once. If a station is contacted twice, the second QSO must be clearly marked as a duplicate and does not count.

ENTRIES:

Logs must be postmarked no later than December 15th and sent to: Landesverband Salzburg des OVSV, "AOEC 1976," c/o Ing. Wolfgang Latzenhofer OE2LOL, Pfeifferhofstrabe 7, A-5020 Salzburg, Austria.

10 METER GROUND WAVE CONTEST

9 pm to 1 am local time, November 27

This is the 24th annual contest sponsored by the Breeze Shooters of PA. All modes are permissible with points determined on a distance and input power basis. Separate awards for leaders in four circular zones centered on downtown Pittsburgh PA. Mobiles and Novice/Technician also compete for separate awards. Logs must be postmarked no later than December 6th. Log sheets and complete rules are available from Richard Evanuik WA3LUM, 311 Evergreen Ave., Pittsburgh PA 15209.

CQ WW DX CONTEST – CW

Starts: 0000 GMT Saturday, November 27
Ends: 2400 GMT Sunday, November 28

The contest is open to all amateurs and all bands. 160 to 10 meters may be used. Stations are permitted to contact their own country and zone for multiplier credit. The *CQ* Zone map, DXCC and WAE country lists, and WAC boundaries are standards.

CLASSES:

Single Operator – single or all band; Multi-Operator – single or multi-transmitter (all band only). Also, club competition.

EXCHANGE:

RST and Zone.

SCORING:

Contacts between stations on different continents count 3 points. Contacts between stations on the same continent but different countries count 1 point. For North America stations only, contacts between stations within NA count 2 points. Contacts between stations in the same country are permitted for multipliers but do not count for QSO points. The multiplier is the total number of different zones and countries worked on each band. Final score is the sum of QSO points times the total multiplier.

AWARDS:

First place certificates will be awarded in each class in every participating country and in each call area of the US, Canada, Australia, and Asiatic USSR. Final results will be published in *CQ*. To be eligible for an award a single operator station must show a minimum of 12 hours of operation. Multi-operator stations must operate a minimum of 24 hours. A single band log is eligible for a single band award only. Second and third places will be awarded if warranted. There is also a long list of trophies that will be awarded.

LOGS:

All times in GMT. Indicate zone and country multipliers only the first time worked on each band. Check for duplicate QSOs and correct QSO points and multipliers. Use a separate log sheet for each band. For official logs, summary sheet, and zone maps, send a large SASE to: *CQ* WW Contest Committee, 14 Vanderventer Ave., Port Washington, L.I., NY 11050.

Logs should be postmarked no later than one month after the contest and should be sent to the address above. Indicate phone or CW on the envelope.

Note: These rules were taken from last year's contest.

LETTERS

from page 15

itoring the CB channels, where, even though I could raise a repeater at all times on the trip, 9 out of 10 times no one was around. Of course, the number of CBers vs hams accounts for this.

I feel the problem with the ham ranks is the typical ham who looks down on the CBer. Here at Norton AF8, San Bernardino, California, we have combined the amateur radio club, CB radio club and MARS support group. Since the CB club's start in March, 1976, approximately 30 CBers have gotten their ham tickets. Most CBers want ham tickets to get off the crowded CB bands. They need the help of a few amateurs to do so.

I hope more amateurs will help, because if they don't, the ham bands will become CB bands when the Communicator licenses are granted, if these CBers are not properly trained. As an added note, in this area 1 of 4 CBers also holds an FCC Commercial license, where it's lucky to find 1 in 25 hams with a Commercial ticket. I realize this is a special group of hams and CBers on a military installation, but would be willing to bet that, overall, it's pretty close to the same percentage. Thus, the CBers *are* interested in electronics – maybe much more than many amateurs I know.

I think more ham clubs should sponsor CB clubs, and then many of our problems would be solved – especially in attitudes on both sides.

Lee Wm. Cook
AFB8WNK/WA8WNK/6
Norton AFB CA

COMMON SENSE

Congratulations on a fine publication: *73* is the first special interest magazine I have encountered that covers a broad range of topics without losing the beginner or the expert, and your ad layout is superb as it does not dominate the content. One criticism, however – with the pages and pages of copy that obviously go into the editorials, when does the editor have time to *edit?*

One thing that really caught my eye was "Hamburglar." The key here is common sense. To reiterate:

1. Do *not* talk about your equipment on the air. We all like to boast about our prized belongings, but remember that monitoring the airwaves is fair game and you have no idea who is listening – *especially* on 2 meters.
2. *Anticipate* being ripped off. Wire your shacks and cars for "sound." It won't guarantee safekeeping, but the chance of catching or at least scaring off the culprit will increase tenfold. It's merely low cost insurance.
3. If you're operating 2 meters mobile (and it's most likely you are), take a look at your installation from about 20 feet away. Glance through the window at your rig. You'll really be startled at the resemblance it all has to a CB setup, especially if you have a 5/8 wave or collinear whip. So if you think you've been ripped off by the all-too-common CB thief, you can really kiss your rig goodbye, as somebody will eventually hook it up to a CB antenna and blow the final sky-high.
4. A word to the wise is sufficient. If you think there is dirty work afoot (you people in central Colorado should pay attention), get the word around – *quick* – and use the telephone. Stay off the air and hide your gear, and with more emphasis, *stay off the repeaters.* During such times it is important to stay low. It's kinda like a scant bathing suit – the more people who know means a better chance of getting burned . . .

I heard somewhere among the pages of the 8/76 issue some grousing (albeit minor) about the intermod on 2 meters. What are you guys complaining about? I am one of those black sheep of the communications world, a scanning monitor listener, and you have never heard intermod like you get on 99-44/100% of the commercially available scanners. Front ends on most of this equipment are as broad as barns and the i-f filtration is no better. Try this – take one ham broadcasting at about 144 MHz and one police department dispatching at just under 155 MHz. If the difference happens to be 10.7, scanner users may as well turn off the power, because the first i-f is swamped and the bad filtration in the 2nd i-f helps matters little. (I'm not pointing any fingers – the same thing happens with police and commercial mobile telephone at 165 MHz.) At any rate, it's bad, especially here in the Los Angeles area where there is an unusually high concentration of rf in the 144-174 MHz range.

In closing, I'll admit that I am not a ham, but that I would like to become one. Only one thing is stopping me – the CW requirements (I can already see thousands of you ready to jump on my case). I cannot see why I have to relive the history of radio communications via International Code and flea power when my primary interests are FM radiotelephone and data communications on 2 meters and above (with a special weakness for omnidirectional work on ¼ meter). Someday, I hope, the regulations will be relaxed and amateur radio will be allowed to catch up with the rest of the communications world.

HAMM ACT?

How about adding additional counts to the indictments in "Hamburglar," e.g., Purloined, Heisted. If transported across state lines, is it a violation of the Hamm Act?

Nubar Tashjian K6KVX
Oakland CA

BUG VI

I enjoyed your "fast shuffle" editorial in the September *73*, and "them's my sentiments," exactly! Like we are being administered by a bunch of kids. Perhaps with a new consumer-oriented administration we will fare better!

There was an error in my letter that was published in that issue commenting on your I/O editorial, in that my draft did not correctly get translated into the final copy. We have the *potential* to accept ASCII at the ATV repeater, but pending an OK on our petition or similar RMs, individual amateurs may not transmit ASCII except through OSCAR. The same action, however, could be triggered by any other means, such as CW combinations, RTTY, etc., though clumsier.

In this connection, you might check on touchtone pads, and Part 97.117. If I read it right, you could also get a pink ticket for using that unauthorized code. And thousands per day, too!

Charles E. Spitz W4API
Arlington VA

WORTH ITS PAPER

Help! Your mag is great, but the advertisers don't want to know about export orders. I have an import permit for R5000.00 (about seven thousand dollars) but no one answers my letters. You should try getting on moonbounce with the parts available here. I want to import just about anything in ham gear for the guys here, so perhaps you have a few good people to recommend.

We have a new repeater here in Johannesburg, and 2 is going crazy with A2C, 7P8 and 3D6 all getting in on the act. The frequency is 145.05/65 for anyone coming this way.

Next problem – I've just received your April issue a week earlier than usual.

Keep up the good work. At 3 dollars a copy there's only one mag that's worth its paper as far as I'm concerned.

C. R. Newport ZR6CW
Northcliff, South Africa

FIVE YEARS AHEAD

I would first like to say I truly think that *73* is five years into the future as to where ham radio will be.

When you first started putting out *73* with the new I/O computer sections, I thought it was a big waste of space and at one point I was thinking about not even renewing my subscription (as you could tell by the big lag of time after my last subscription terminated until I sent in my 3 year subscription). I now have a minute understanding of ICs, and I am developing an interest in computers for which your I/O section proves to mature my interest. If I remember right, my interest in ham radio started with me reading publications about ham radio. Could it be possible that after reading your I/O section for a few more months I might wish to purchase a computer?

Steve Branom WBØOIS
Des Peres MO

WRITTEN CRAZINESS

The written craziness appearing in the first three issues of *73* delivered to my door has prompted me to send in my $8.00 so that maybe I can understand the present by reviewing the past. After reading only official ARRL books, my closed mind was opend to a breath of fresh air upon my initial exposure to a copy of *73*. Aren't the low bands all there is to ham radio? After reading all the ARRL books I thought I was second best with my little Technician license, but after reading your articles I realize I'm right on top of the heap. After all, I was only looking for some dependable local communication when I sought the Tech ticket, not a way to talk to some people I've never even met in some country I have never even heard of.

I started this course after being in the middle of CB here in Memphis for the past ten years. Neighbors used to speak under their breaths as my brother and I drove by, calling us, "Those funny people with those strange radios in their cars and those funny antennas." Then, at the precise moment of my life when I was ready

to sell out of CB, a friendly ham introduced me to a handie-talkie. I was hooked. No more would I have to call for my friends in vain on the CB when their units wore off. With an HT all I needed to do was punch up the patch and ring their phone. Total communications right in the palm of my hand.

Well, I'm into it now and with about two hundred avid listeners on the two meter autopatch repeater I'm a little bit shy about calling my CB friends who think it's cute to say 10-4 on two meters. And the guys on the machine have had their clique set up for at least a hundred years and don't have a thing in common with a converted CBer, so even with a handful of total communications I'm still stuck.

I work with CB everyday in my job at the local shack, so I know what it is, and I know what two meters is here in Memphis. Both are a real strikeout. You've been pushing both, but from my position neither one is worth the pushing. The real friendly folks who enjoy the art of conversation and enjoy listening to other people talk are the people in Memphis on six meters.

With a new six meter repeater and an ever-expanding club as a result of the six meter repeater — not to mention the two meter repeater of theirs now going through testing — this is the real home of amateur radio in our community. As usual, about half the ham population in our town is ignoring it.

So maybe that's why I still read your magazine — kindred spirits? Your brick wall at the ARRL is just about as big as the brick wall our group runs into every time we try to do something with another ham group here in town. If it's not pickiness, it's personalities they're objecting to. Cooperation is the key to success (to coin a phrase), and if there weren't a few good hams in the two meter group, I doubt if anything would get done by a combination effort. God bless 'em. 73s to *73*. Ship my 20 back issues quick and I'll keep reading your mag, no matter how many computer articles you put in.

John Wood WA4BPI
Memphis TN

P.S. By the way, check out the *QST* covers for July and June, 1976. Each story the cover promotes is in the other issue. The June "Amateur Radio at the Olympics" story is found in the July issue on page 50. The July story, "The ARRL Nat'l Convention, *Denver*," is found in the June, 1976, issue on page 53. Obviously you've noticed it, but since you didn't mention it in your September, 1976, issue, I thought I'd pass it along. Hope it gives you a laugh — it did us.

Okay on the QST covers . . . I hadn't noticed. Re 2m vs. CB vs. other ham bands . . . I suspect that we will get out of our hobby about what we put into it. Since most of my operating these days is while I'm driving, and since the driving process takes much of my attention, I'm afraid that contacts with me on 2m or CB are probably pretty dull. Any other readers with ideas on this? — Wayne.

GOODIES

On reading the I/O Editorial in the August *73*, I felt it necessary to let you know how much the I/O features are appreciated by some of us in the UK.

Here, as in most of Europe, the low end of the computer market has been neglected, and our present awareness of trends in the US of what must eventually turn out to be an enormous worldwide market is largely due to the features and advertisements that have appeared in *73* since November 1975.

My experience with a modest 6800 kit convinces me that you are perfectly correct in foreseeing a growing use of microprocessors in amateur equipment, and I only wish that we found it easy to import some of the "goodies" that are advertised so tantalizingly in your magazine.

You mention that a new magazine covering the computer hobby field may be introduced, and I hope that when this happens, the *73* agent in the UK will be able to handle subscriptions to it.

Finally, as a radio ham with a professional connection with large computer systems, I would like to say a sincere thank you to *73* for what has appeared so far, and for what I hope will continue to appear in the future.

W. D. Old G3CZZ
Camborne, Cornwall
England

HELL-BENT?

Would you please explain to me why you and other magazines seem so hell-bent on recruiting new members to ham radio? I am sincere when I say I really do not see any advantage to me by increasing the clutter on the air. Of course, I can see why *you* would want an increase — for more business, of course — and I don't blame you.

That goes for manufacturers of equipment — also more business. But why should I encourage people to be new hams? Have you ever tried to get on 20 meters around 6 o'clock in the evening? Have you ever heard the incredible pileups when DX starts to come in? The QRM is impossible.

I am not trying to be sarcastic with this letter. I really would like to know why it is to my advantage to encourage new hams. You may use this letter if you want to — possibly others may feel like I do.

Harry Torossian WB8SWD
Dearborn Hgts MI

Well, Harry, though parts of 20m may be overoccupied, even at peak hours of activity there are large parts of our ham bands which are almost unused. The "use it or lose it" theory is a valid one, and the fact is that we have far too few amateurs to use the channels allocated to us. When you have trouble getting through on 20m, you might tune up to 15m and be amazed at the wide open (unused) spaces. If that doesn't impress you, then tune the 1.7 MHz of 10m and listen to nothing. Up on 6m there is maybe 500 kHz of activity and 3.5 MHz has very, very little. In most areas of the country 144-146 is dry. And with the exception of a handful of pioneers and a few pioneering repeaters, 220-225 MHz (the band manufacturers want for CB) is empty. 420-440 is dry in many areas . . . and above 1215 MHz what have we? It does me no good to print a lot of articles exhorting hams to use these bands, for if they do then we will have less use of the other bands. We are spread so thin as it is that about 50% of the 2m repeaters are hurting badly for activity. If you want to really feel lonely try going on 6m or 220 MHz repeaters . . . with a very few exceptions. Yes, we are in great need of amateurs if we are going to have reasons to hold our bands . . . or to get more bands. If we continue to force all newcomers to come into amateur radio via the lowband $800 transceiver route (Novice license), we will end up with more and more jamming of the few low band frequencies and a continuation of the wide open VHF and UHF ham bands. Yet, with the discontinuance of the mail order Tech license, this is exactly what the FCC has brought about. — Wayne.

LESS AND LESS

First, thank you very much for the copy of the July issue. I have a subscription, so I got to see my article on computer Morse when it first came out. When that other copy came, I had further proof you and your staff have it where it counts — concern for people. You encouraged (almost cajoled) me into writing the article with your editorial calls for attempts. Then, to my astonishment, you publish it, my first ever attempt at publishing anything. Now, you make sure I have an extra copy to remind me to write more and better. Thank you all, very, very much.

The rest of this you may use in your Letters department if it would be of any value to your readers.

After reading three or four editorials of yours saying CB is not all that bad (or is it not all CB is bad) and talking with some local search and rescue people to make sure, I mailed in a CB application on 31 May. I settled down to wait the four months. Then I got the info on temporary licenses, filled out a form, bought two walkie-talkies for use on my impending vacation. I considered "bending the rules" after my 60 days were up. Then I realized that the main complaint against CB is people "bending rules" to one degree or another. I resolved that I would not attempt to face that moral issue until I actually was tempted to operate illegally. On 12 July my license arrived to the relief of my overtime conscience. 43 days' delay, and since my license was approved on 23 June, I suspect that a large part of that was in the postal system. It seems that the FCC is responding to the flood of CB applications. I wonder what else they will be doing for that large block of people.

By the way, out here I have never heard more than five channels busy at any one time. Occasionally, I hear callsigns used. I haven't heard a foul mouth or a conversation I wanted to join yet. My wife and I have found our walkie-talkies extremely useful, and we will continue working with search, rescue and service groups.

The article by Fields in the September issue ("How to Catch a CBer," pp. 74-77) was first rate. I learned a lot about CB from that article. I think we have to incorporate anything from CB that will serve a useful purpose. If we don't start selling ham radio on its merits, CB will remain in the spotlight. That means *they* will get the publicity and praise that leads to support in Congress and at the FCC. That means more goodies for *them* — which leaves less and less for us.

James Whitfield
Edwards AFB CA

SNEAKING ONE OVER

Finally, through Docket 20282, the FCC does something positive for ham radio. I am referring to the provision in the docket which allows for Novices to use 250 Watts of power. It also restricts other classes of licensees from using more power than that in the Novice portions of the bands.

I agree with you that now Novices can purchase the latest state-of-the-art transceivers. This will definitely aid Novices in the crowded bands.

After reading of these changes in the ham magazines, I went out and bought a new Yaesu FT-101E with accessories. I spent about $1000 on this rig. I am expecting my Novice ticket soon, if the FCC ever finishes grading it and issues my ticket.

What I wanted to inform your readers of is that "Mother" ARRL in the June 12, 1976, meeting of the Executive Committee unanimously *voted* to petition the FCC *to reconsider* that portion of Docket 20282 dealing with the 250 Watt power proposal for the Novice bands. I for one am very disappointed with this development. Not only have I invested a considerable amount of money in gear which today is legal, but tomorrow may not be, but also the ARRL, which is supposed to be looking out for ham radio, is trying to sneak one over on all prospective as well as currently active Novices. What I really

New Products

NEW 5½, 6½ DIGIT DIGITAL VOLTMETER CHECKS AND CALIBRATES ITSELF

Using two microprocessors, one for measurement control and the other for computation and remote programming, this new fully-guarded, integrating Hewlett-Packard Model 3455A Digital Voltmeter is a high-performance unit designed for bench or systems use. It measures dc from 1 uV to 1,000 volts, true rms from 10 microvolts to 1,000 volts, or, with an optional average ac converter, from 10 microvolts to 1,000 volts average. Resistance measurements cover from 1 milliohm to 15 megohms in six ranges, either two or four wire. A high-resolution mode uses 6½ digits, but for faster reading 5½ digits are used.

Use of a plug-in precision reference enables the instrument to check itself against the reference. Under control of the microprocessor, it makes its own corrections. The reference unit can be easily removed from the 3455A and calibrated periodically. A self-test feature verifies operation of the dc circuits. If a problem is found, it is easily analyzed using the front panel display.

Mathematical functions built into the 3455A let the user offset, take ratios, or scale readings so that readouts are in physical units. A "% ERROR" mode converts readings into percent change compared to a predetermined reference.

Dc measurements are made at 24 readings per second (22 readings per second for 50 Hz) with 1 microvolt sensitivity. Greater than 60 dB normal mode noise rejection is obtained on all dc ranges. Dc accuracy is ±0.0023% at full scale.

True rms measurements are made to 13 readings per second at frequencies above 300 Hz. True rms is measured with best accuracy of 0.1% over a 30 Hz to 1 MHz bandwidth. Signals with a crest factor as high as 7:1 full scale can be measured.

Average ac measurements (optional) are also made up to 13 readings per second at frequencies above 300 Hz. Average ac is measured with best accuracy of 0.1% over a 30 Hz to 250 kHz bandwidth from 1 to 1,000 volts in four ranges with 50% overranging. The Model 3455A can be ordered with Option 001, which provides average ac instead of true rms, at a reduced price.

Resistance is measured in six ranges from 100 Ohms to 10 megohms full scale with best accuracy of 0.0025% at full scale. Maximum current through the unknown is less than 1 milliampere. Internal circuits are protected against overvoltage.

Standard on the 3455A is an HP-IB (Hewlett-Packard's implementation of IEEE-488) I/O for systems operation. The front panel indicators on the 3455A display range, function and HP-IB status during remote operation.

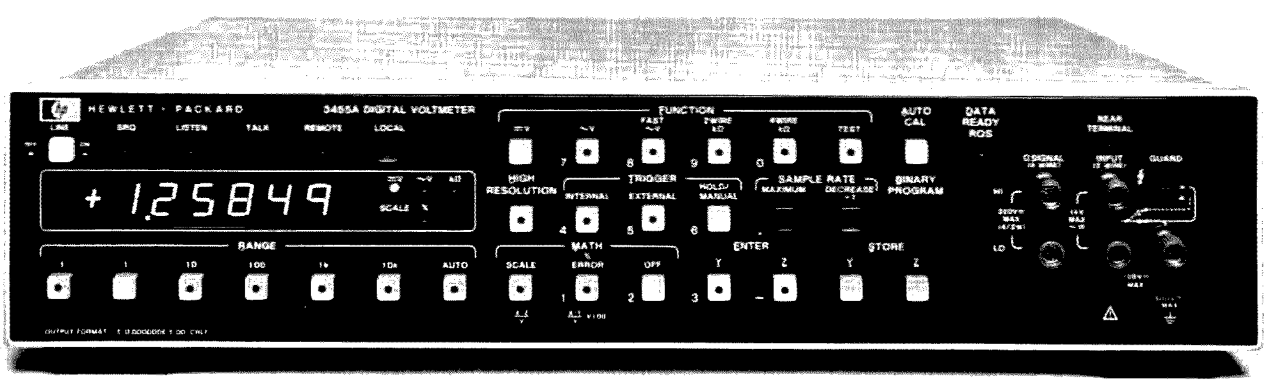
The U.S. price of the Hewlett-Packard Model 3455A Digital Voltmeter, including true rms measurement capability, is $3200. Model 3455A with Option 001 replaces true rms measurement with average ac measurement and sells for $3000. *Hewlett-Packard Company, 1501 Page Mill Road, Palo Alto CA 94304.*

THE TF40 POCKET CRICKET

Sencore, Inc., manufacturer of electronic test and measuring equipment, has announced the release of an all new portable transistor/FET Tester: The Patented TF40 Pocket Cricket.

Bob Bowden, Sencore's Marketing Director, explained, "According to EIA figures, more transistors and FETs have been used in the last five years than any other active component, which means the service and maintenance of these components will be an ongoing process for many years to come, in both the consumer service market (including radio, TV, stereo, sound and communications) and the rapidly expanding industrial MRO (Maintenance Repair Operations) and medical test equipment markets."

The tremendous need for a fast, reliable GO/NO-GO test of transistors and FETs was clearly demonstrated by the overnight success of Sencore's patented TF26 Cricket transistor/FET tester, introduced three years ago. Since that time, the Cricket has become the most popular transistor/FET tester ever produced, with over 30,000 Cricket circuits in the field today. The Cricket has established itself as a standard in the industry for



speed and reliability.

However, there was a growing need for portable testing capabilities for numerous applications where on-site transistor/FET testing is required, such as field service work of medical products (where ac power may not be provided), consumer products service, business machines service (copiers, typewriters, and word processing units), general maintenance of industrial equipment, mobile communications stations, avionics, and numerous other applications. No reliable answer for this need for portable transistor/FET testing was available until now, with the patented TF40 Pocket Cricket.

By implementing a low current drain state-of-the-art design, the TF40 Pocket Cricket now incorporates the 99.9% reliable Cricket in a small, compact, rugged design for the first reliable, completely portable transistor/FET tester to meet this tremendous need for field maintenance and service of solid state equipment.

Mr. Bowden said, "The Cricket circuit tests all transistors and FETs in seconds using a Sencore-patented universal phase inversion test based on the fact that all transistors/FETs amplify and invert a signal if the device is properly working. Total GOOD/BAD testing takes only seconds and requires no setup information. The test leads are connected to the transistor in any order and the test switch is rotated. If the transistor is good, the Pocket Cricket will chirp and the meter will read upscale." (The test tone was added because the test can be made so quickly the meter may not have time to read upscale.)

Once a transistor is known to be good, the polarity can be determined and a transistor can be distinguished from an FET. This is extremely helpful in establishing a replacement part of a schematic is not available. And, the Cricket test circuit is 100 percent safe to the tester, circuit, and user.

Many times a transistor will show good gain, but not operate in circuit due to inter-element leakage. To be as reliable as possible, the Pocket Cricket is designed to measure all individual inter-element leakages on the meter for a 99.9% reliable check of all transistors and FETs. The Pocket Cricket's metered leakage test is exclusive in pocket portable transistor testers, offering the most reliable test available for field use.

For the first time in a portable transistor tester, all three transistor leads can be identified, in seconds. The exclusive lead ID control is adjusted until only one of two positions on the test switch indicates a good transistor. The lead configuration then can be read directly off the coded test switch. This feature can save time in determining proper basing configurations, without the use of reference material.

Included with every TF40 Pocket Cricket is a specially-prepared training tape explaining the overall operation and application of the TF40. Mr. Bowden explained, "The Pocket Cricket is an extremely versatile, reliable instrument that will undoubtedly be used by thousands of people in plants, field job sites, large service shops, and schools. The training tape is designed to give any new operator the basic instructions he needs to put the TF40 to work for him as soon as possible. With such a tremendous need for on-site servicing, the patented Pocket Cricket should receive tremendous response from all areas of the electronic maintenance and service markets, especially considering the low $98 price, plus the fact that the Pocket Cricket carries Sencore's 100 Percent Made Right Lifetime Guarantee, insuring a lifetime of performance free from factory workmanship error." *Sencore, Inc., 3200 Sencore Drive, Sioux Falls SD 57107.*

UC 1800 MICROCOMPUTER

The UC 1800 is a completely self-contained microcomputer designed to allow maximum ease of use.

It has significant value as a training device in the construction and use of computers in general, and as a device for evaluating the application of a microprocessor in new products.

The UC 1800 is completely assembled and tested. As such, it has important design cost saving advantages to industrial users contemplating the use of microprocessors in their products.

The comprehensive instruction manual, simple straightforward software instructions, self-contained keyboard, and four digit hexadecimal display provide a package which promotes rapid training and system development.

All users will benefit from the growth potential incorporated in the UC 1800. External bus access allows future connection to a host of peripheral devices and add-on memory which can provide full mini-level computer power.

The user of the OEM version will find such features as full military temperature range, low power CMOS, single 3 to 15 volt supply and TTL compatibility are decided advantages in a wide range of product applications.

The outstanding features are: low cost, built-in keyboard programming, digital (hexadecimal) display for address, memory contents, and I/O port, front panel control of interrupt, DMA, I/O flag, 256 byte RAM expandable to 65.5K bytes RAM or ROM externally, low power consumption, special circuit for saving memory content when unit is turned off, single power supply, parallel and serial I/O data line capability, availability as single PC board microcomputer with or without on-board power supply for OEM applications.

Applications include use as a computer training device for schools and industry, microprocessor application demonstrator/evaluator, software development trainer, household or hobby computer, or small business or industrial computer. The UC 1800 may also be used for process control, laboratory automation, traffic control, and data communications. *Infinite Incorporated, PO Box 906, 151 Center Street, Cape Canaveral FL 32920.*

NATIONAL SEMICONDUCTOR CORPORATION CONSUMER PRODUCTS DIVISION ANNOUNCES TV "ADVERSARY" GAME

National Semiconductor, Consumer Products Division, has announced it has received FCC approval for its TV game, "Adversary," which was previewed at the Consumer Electronics Show in Chicago June 13-16, 1976.

The video game, "Adversary," features a choice of 3 playing fields: Tennis – played by one or two players on green court; Ice Hockey – played by one or two players on blue ice; Handball – played by one or two players on brown court.

All games are in full color, have realistic sound effects when the ball or puck strikes a surface, and offer a choice of 3 individually-selectable paddle sizes. Serves are controlled by players, not by random. Scoring is automatically displayed in large easy-to-read numbers after each point is scored, and is off during play. Controls are individual, which enables players to sit in a favorite chair to compete.

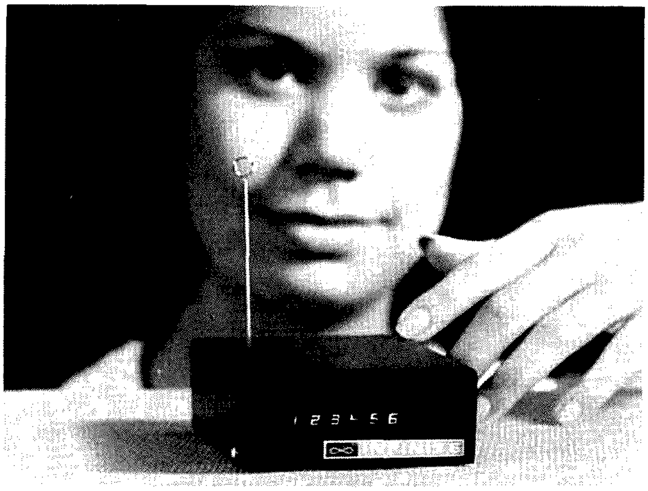
"Adversary" offers 7 modes of operation: 3 modes of 2 players, 3 modes of player against himself, and 1 mode with player against machine.

A special feature allows "time out" during play without changing the score. Play can be resumed at the point where "time out" was called.

"Adversary" employs National Semiconductor's recently announced MM57100 video game logic circuit and LM1889 video modulator. *National Semiconductor, Sunnyvale CA 94086.*

ALL NEW SOLID STATE DC101A AUTOMOTIVE DIGITAL CLOCK

The DC101A digital clock sets the trend in digital automotive electronics which will be offered in the upcoming years. Its small size (1¼" x 2¼" x 5/8") and coordinated leather texture and chrome exterior make it an attractive addition to any car. Solid state electronics and a quartz crystal



produces a clock that is the most modern timekeeping device for automobiles. It can be easily mounted in minutes in its compact ABS plastic case. Installation is accomplished by drilling a nine thirty seconds of an inch hole in the dash, passing the power wires through it, and connecting them to the power with quick-connect fuse clips. Bright light emitting diodes allow for easy reading in all conditions. Since the clock is all solid state, it is inherently long-life. A one year guarantee is offered on the clock. Price: $49.95. *Lectronix, PO Box 42, Madison Heights MI 48071.*

NEW CUSHCRAFT FACILITY

Construction is underway on the first phase of CushCraft Corporation's new 50,000 square foot antenna research and production facility.

All manufacturing operations, executive offices and research will be moved to the new facility by November 15th. It is located at the Grenier Industrial Park in Manchester, N.H.

Bob Cushman, treasurer of the company, reports this all new plant is designed specially for antenna manufacturing. It will allow increased production of current amateur, citizens band and professional antennas — plus the introduction of several new antenna types.

Planning for the new production lines and equipment has been in process for several years. When fully operational, the plant will be a model for the industry, allowing CushCraft to maintain its traditionally high value standards.

FS 20 FIELD STRENGTH METER

The FS 20 Field Strength Meter is a wide bandwidth, extremely high sensitivity, digital readout rf power monitor. This instrument is highly suited for monitoring the output power performance of communication transmitters over an extremely wide frequency range without connection to the transmitter.

All two-way radio users want the confidence of knowing their transmissions are getting out. The field strength meter approach to accomplishing this is especially valid since the *radiated* power from the antenna determines the reading obtained on the FSM.

Consequently, anything that causes a loss of rf power will be detected, be it a damaged antenna, loss of input power, or circuit defect. This is not necessarily true of in-system monitors. Some unique features include: six digit LED digital readout; battery or external power; instant Velcro attachment to metal, plastic, or wood; small attractive case design with non-glare epoxy finish; thin flexible antenna.

Weighing six ounces, the FS 20 FSM has a frequency range of from 2 MHz to 1100 MHz. Its dimensions are 5½" x 3" x 1¼". Applications include monitoring transmitter power, transmitter tuning, preflight radio checking, locating rf leakage points, adjusting antennas and transmission lines, locating radiating ELTs, locating radio bugs, and independent testing of EPIRB units. The FS 20 also satisfied FCC requirement 83.528 for marine VHF. Option 001, a high intensity readout, adds about three times the normal brightness and sells for an additional $5.00.

Each FSM is guaranteed for a period of one year. A modest fixed price repair service is available after the warranty expires. Introductory price: $49.95. *Infinite Incorporated, PO Box 906, 151 Center Street, Cape Canaveral FL 32920.*

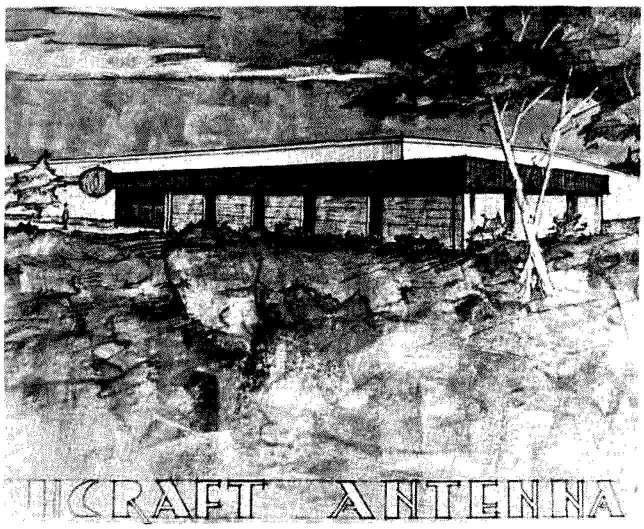
NEW LOW POWER, LARGE MONOLITHIC LED DISPLAYS

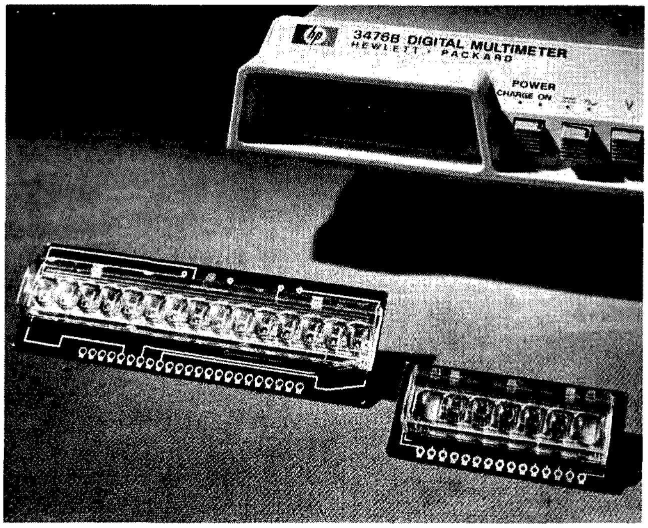
This new series of 4.45 millimeter (0.175 inch) high, seven segment numeric displays require only two milliamperes per segment — about 1/3 the power required by presently available displays. Designed for instrument applications, these HP 5082-7265, -7275, -7285 and -7295 LED indicators are available in five and 15 digit packages.

Close digit spacing of four digits per inch, combined with low power requirements, now give the designer of portable digital instruments, desktop calculators and other digital devices a large, easy-to-read display. They can be driven directly from MOS circuits.

Models 5082-7265 and -7275, five and 15 digit clusters respectively, have a center decimal point. Models 5082-7285 and -7295, also five and 15 digit clusters, have a right decimal point. Devices may be mounted with edge connectors or soldered wires.

Necessarily more costly than smaller displays, the five-digit 5082-7265 is $11.25 in quantities 200-999; the 15-digit 5082-7275 is similarly $31.95 (U.S. prices). *Hewlett-Packard Company, 1501 Page Mill Road, Palo Alto CA 94304.*





Cordless Iron Tips

-- when you're up against the Wahl

David F. Miller K9POX
7462 Lawler Avenue
Niles IL 60648

No, not the kind of tips that heat up, the kind of tips that keep the latter heated up! In a recent advertisement, the Wahl soldering iron people set forth the claim that many users have said that their $20 cordless soldering iron is worth its weight in gold. Ever since my wife bought me one two Christmases ago, I'll have to agree that for numerous tasks around the ham shack it is almost indispensable, especially once you get used to having one of the darn things. For example, for antenna jobs 150' from the nearest ac outlet, small "quickie" soldering jobs when you don't have time for the "landlocked" iron to get perking, and for mobile or vacation jobs to fix that intermittent *when* it happens. The extra fine tip that's available for these irons is great for making accurate joints on those little bitty circuit board pads that seem to be in the vogue now (you know, the ones that turn to goo with an American Beauty). The model that I have (Wahl 7500) comes with a charger stand, and all you have to do is drop it in the stand to revitalize those two little 1200 mAh nicads inside.

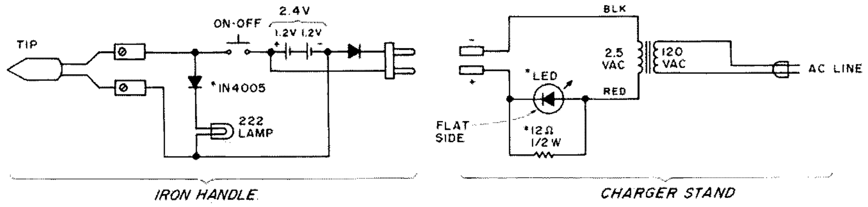


*Fig. 1. Wahl Model 7500 iron and stand. 90 mA total: 30 mA through LED, 60 mA through 12Ω ½ W resistor. * indicates parts added; all others are part of original circuitry.*

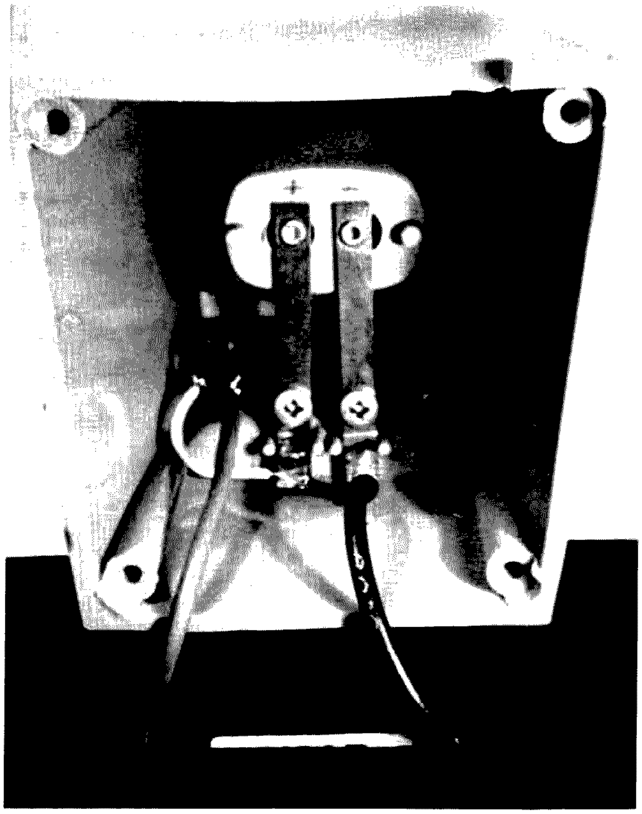
I often wondered whether or not the two contacts on the iron were making good connection with the matching contacts in the stand (I worry about things like that). After all, the iron element draws about 5 or 6 Amps when the cells are fully charged, which represents about 10 to 15 minutes of actual soldering, so it's important to keep it up to maximum in order to have it when you need it. I usually ended up jiggling the iron around in its stand just to make sure. The charging stand as it comes from the factory consists merely of a 120 V ac to 2.5 V ac transformer and the two mating contacts (Fig. 1). My unit has the *non*-rapid charge cells, so the maximum safe charging rate is 1/10 of 1200 mA, or 120 mA. Notice the clever placement of the diode in the iron itself so that reverse charging from the stand is impossible. (Also, if the charging terminals on the iron accidentally short to something metal, the nicads won't discharge because the diode won't conduct that way.) Back to the point: I took it upon myself to install an LED (light emitting diode), polarized as shown, in series with the red charger lead inside the charger itself. I chose to limit the charging current to 90 mA (nice and safe) with 30 mA through the LED (bright enough and also safe) – hence the 12 Ohm, 1/2 Watt resistor paralleling the LED. Now when I drop my iron into its stand I'm sure that it's taking a charge by the fact that the LED is releasing photons.

The actual modification is quite easily accomplished in one evening. I used a diffused red LED that required a 3/16" mounting hole deftly drilled in the front of the stand. After checking the fit and deburring the hole, apply a couple of drops of epoxy from the inside to hold the LED nicely. Clip the LED leads to a convenient length and make small loops in them to act as tie points for the resistor and charger leads. Incidentally, I've noticed rather wide variance in light output, current drain and chip centering in surplus LEDs, so check the device before committing yourself with epoxy. You may find that you will have to choose from several devices to get the desired results. All that's required to custom tailor this idea to your hardware is a meter that will read at least 100 mA, a few test leads with alligator clips on them, and some resistors (or a pot) around the value shown. If you don't worry as much as I do, you can just copy the circuit as shown and you'll be in the ball park.

As mentioned earlier, you may wish to use your cordless iron in the car or when on vacation, which, of course, necessitates bringing along the charger stand, right? Wrong! Consider whipping up a charger cord that will allow you to charge your iron directly from your automobile, boat, plane, etc., 12 volt system. The tactic that I use involves borrowing the cord from something that must go with you on every vacation (unless you're going camping in the north woods) – your electric shaver. Perchance the ac coiled cords for both my Schick "Flexamatic" and my

Front view of modified charger stand.



Interior view of modified charger stand. LED and its resistor are shown at the left of center.

Norelco "Tripleheader" shavers will mate with the Wahl 7500 iron with minimum modification. I found that I had to shave (no pun intended) about 1/32" off of the female cord receptacle end (completely around) with a sharp knife and then file it smooth to obtain a perfect fit in the iron. Don't get carried away – 1/32 isn't very much; yes, the cord still works in the shaver. I then wired the circuit shown in Fig. 2 into a standard female ac cord receptacle called a "STA-TITE," obtained from the local hardware emporium. Note the inclusion of the ever-present LED to show you when the iron is plugged into the shaver cord properly and/or when the shaver cord is plugged into the dc adapter cord properly. If the LED doesn't light, reverse either end of the shaver cord (no harm done because of that diode in the iron's case). The opposite end of the dc adapter cord is terminated in a standard cigar lighter plug; note that this end is polarity conscious. The present standard seems to be negative ground (lighter plug shell), so wiring as shown will be correct. By the way, this dc cord is intended as a charger cord only; attempting to solder a connection with it plugged into the vehicle's cigar lighter socket will only replace about 90 mA of the 5 or 6 Amps needed to run the iron – and that won't buy you much! The figures on this circuit are identical to the ac charger: 60 mA through the 150 Ohm, 1 Watt resistor and 30 mA through the LED/220 Ohm, 1/2 Watt resistor combination. These figures are based upon 13 V dc input, which is an average lead-acid storage battery value. You can purchase Wahl's plastic carrying tube for the iron, or you can do just as well using a decent 1-3/8" to 1-1/2" mailing or paper towel tube fitted with end caps (make it long enough to house the dc charging adapter, too).

Just as a bit of additional info, I mentioned that the Wahl 7500 cordless draws 5 to 6 Amps from the internal

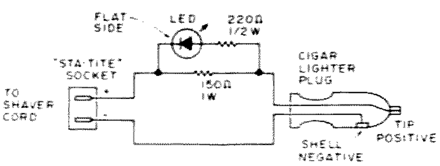


Fig. 2. Dc charging adapter cable for Wahl Model 7500. 90 mA total: 30 mA through LED and 220Ω ½ W resistor, 60 mA through 150Ω 1 W resistor.

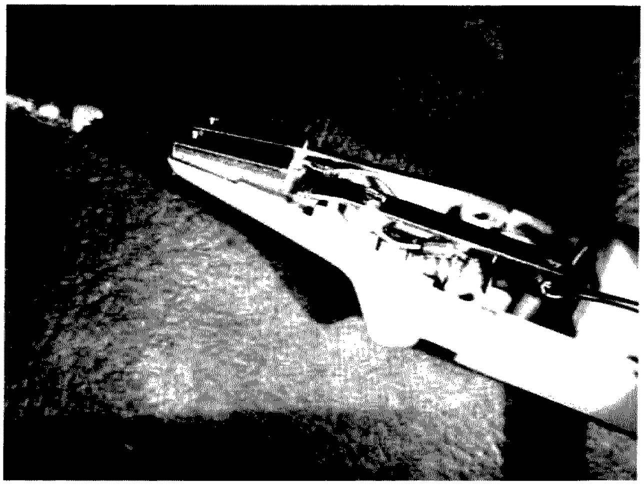

Interior view of iron, showing diode used to slightly drop lamp voltage.

batteries; this is true once the element is hot. The initial current through a cold or cool tip is about 9 Amps, tapering to the above after about 5 seconds. This suggests that the working time between charges is less when the iron is continually turned on and off. I checked my iron against the clock after a full charge and was able to get over 12-1/2 minutes of useful heat in a continuous ON condition. Presumably, off/on operation would yield something less than this. There are all kinds of ins and outs with something as simple as this seems to be, aren't there?

Before you relax for the evening, here's one additional easily accomplished modification, this time inside the iron itself. There's a very handy little light built into the business end of the Wahl 7500, with the nasty habit of burning out too fast. The type 222 bulb is rated at 2.25 V and 250 mA, but the fully-charged nicads put out 2.4 V (under load) and shorten the bulb life quite a bit. I installed a silicon diode (1N4005) in series with the bulb and am getting much better bulb life, plenty of light and more battery capacity for heat instead of wasted light (remember the energy crunch!). With this addition, the bulb has 1.5 V across its filament and draws 200 mA due to the drop across the diode (junction potential). The important thing here is the well-documented fact (in past issues of *73* and other publications) that as you lower the voltage across a lamp from its design voltage, the lamp life increases dramatically (the reverse is also true). Now that you're convinced, just remove the screw holding the bar that makes pressure contact with the shell of the lamp socket and install the diode in its stead, wrapping the anode end around the screw and soldering the cathode (banded end) to the lamp *socket* shell (use minimum heat and remove the lamp first). While you're inside the iron case, put a *small* dab of GC26-01 silicone lube on the switch contact; it's a good all-around contact keeper-cleaner. Note that these modifications directly apply to the model mentioned with *non*-rapid charge cells. However, they could be applied to other models and manufacturers, and, as such, will hopefully act as food for thought.

Now you can relax for the evening and read the rest of *73*, or you could try out your newly modified cordless iron on some of the other interesting projects in this issue, or you could just admire the LED in the stand while the iron is charging. ■

Bicycle Mobile

-- cover feature

After losing ten pounds and logging dozens of QSOs, I arrived at the conclusion that DXing bicycle-mobile is not only fun, but also healthy!

The idea to add a rig to my bike came to me one night, when, after a few hours of sitting in my shack, I took a shower and stepped on the bathroom scale: I was ten pounds over my normal weight!

We have to do something about this situation. I love hamming, but the idea of turning myself into a blob of lard was not very appealing. The doctor agreed with me: I must cut down my hours in the shack and put in some time doing exercises. I started jogging and doing sit-ups. It was exhausting and boring. So I turned to the bike. Not so exhausting, but still boring.

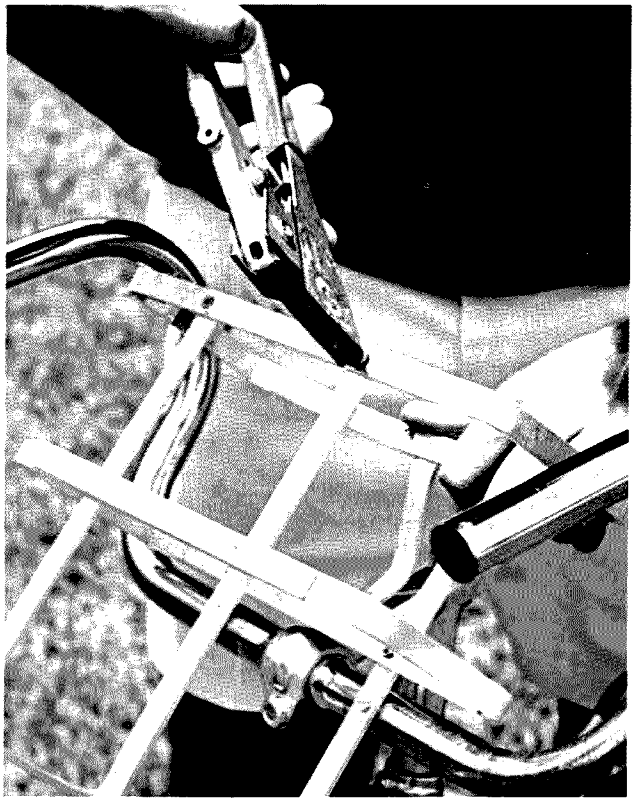
I tried reading while pedaling, but (after a near miss), decided that this was unsafe.

The next day, I brought along my two meter rig. That was quite an improvement. I had a chat with the local boys through the nearest repeater. To improve my signal, I installed an eight wave antenna on the back of the bike; the chitchat expanded to other repeaters.

Then the rechargeable battery gave up, and I installed an outboard heavy-duty battery.

I am never satisfied with what I have, and always seem to want something else. Maybe I was missing my DX friends, because the idea of adding an HF rig to the bike came to my mind. That invisible bulb lit in my head, and I started to look around for the right thing. The transceiver I had in mind had to be light, capable of putting out a decent signal, and, of course, battery-operated.

Even if you find the ideal rig, a friend of mine told me, it's going to be very difficult to use a vertical antenna. The bike is not enough for a ground plane . . .



My enthusiasm was dampened a little, but I decided to try my idea anyhow. I began thinking about building a solid state monobander transceiver. After looking over magazines and books I decided to go by one easy rule: "If you can buy it, don't build it." I got myself one of those little Atlas rigs. The name sounded like it was taken from a moving company, and the appearance was that of a shrunken Swan. The truth is that this tiny transceiver has a tiger in its guts! The only thing you need to operate this rig is a well matched antenna, and a battery with a good Amp hour rating, to feed those hungry finals transistors.

After taking a good look at my old bike, I decided to get rid of the hand brake and install a pedal brake, so that my hands would be free to operate the transceiver.

The Atlas is ideal because there is no tuning or loading. The whole operation is automatic. It's a rig for "appliance operators." If the antenna is matched, as I said before, the only thing you have to do is select the frequency, press the mike's button, and call "CQ."

I installed a rack over the back wheel to hold the battery and the antenna, a Hustler vertical. It is neat, light and well manufactured.

To hold the transceiver between the handlebars, I built a basket out of aluminum strips riveted and fitted to the handlebars with bolts and nuts. The rig sits very comfortably at a 45° angle, for better view and access to the controls. But if you want to spend a few more bucks and save work, Atlas sells a nice mobile rack.

With all the parts in place, my old bike looks like a very interesting contraption. "What will the neighbors say?" my XYL asked me. Well, nobody blinked an eye when we erected the tower and the cubical quad, and this time there is no more reason for anyone to be alarmed.

So I climb on my bike and pedal QSOs. ■

Build a Simple "Lab" Scope

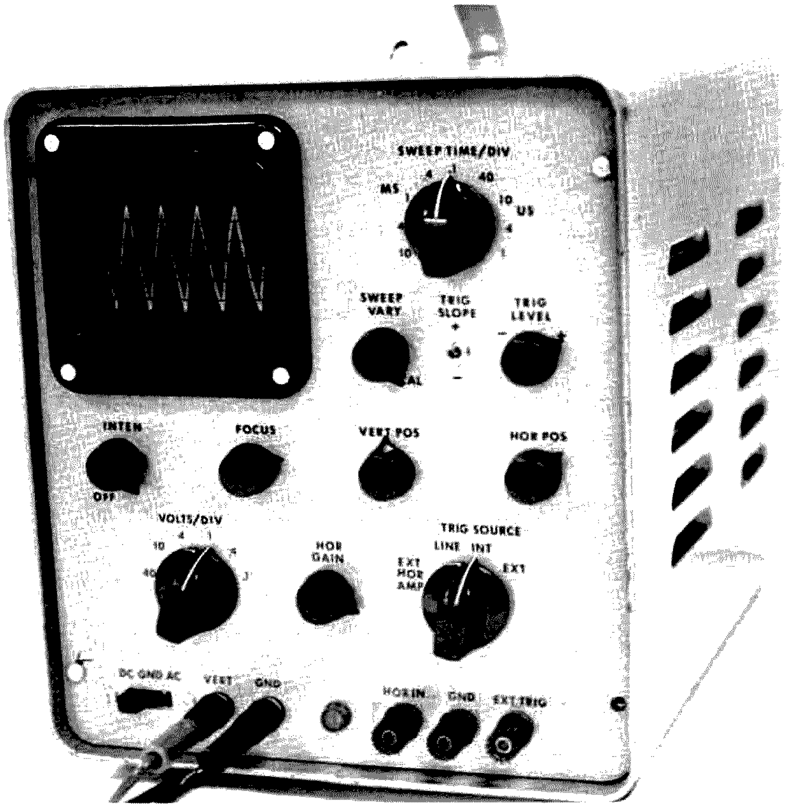
-- costs less than $70!

Watch any industrial electronics technician in action and you'll notice that he relies almost exclusively on his oscilloscope for troubleshooting. It can measure ac and dc voltages as easily and accurately as a VOM, while also measuring frequency, phase and waveshape. It can spot distortion or interfering signals, and can detect missing pulses and slow risetimes in digital circuits. No other instrument approaches it for versatility.

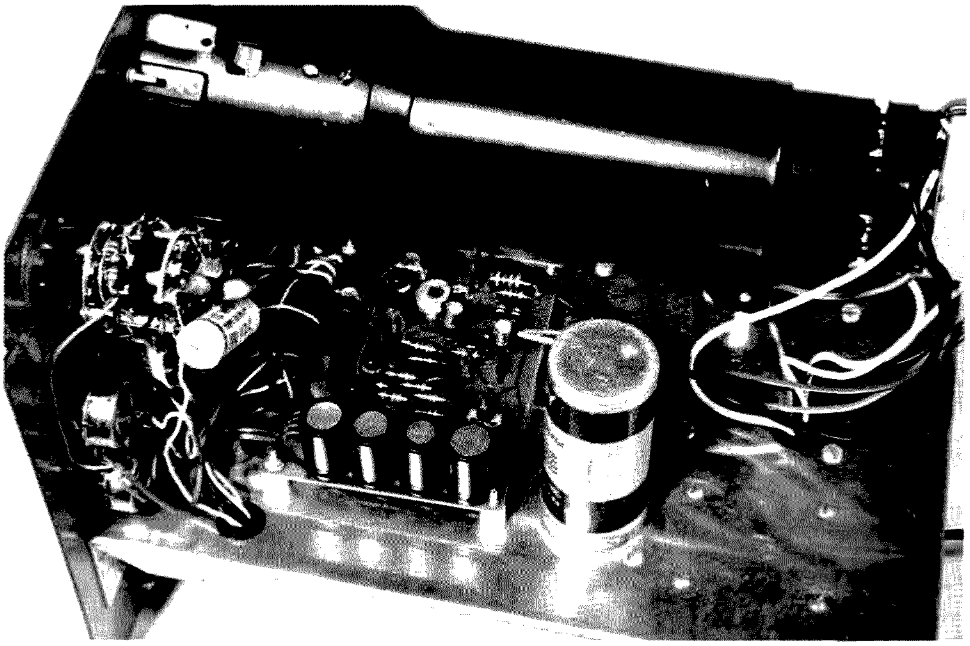
Unfortunately, the cost of lab-type oscilloscopes ($250 and up) has limited the experience of most servicemen and hobbyists to service-type scopes, which are not true measuring instruments, but merely waveform indicators. Most annoying of all, they require constant fiddling with a "sweep" or "sync" control to keep a steady waveform on the screen.

Now it is possible to build an oscilloscope with nearly all of the advantages of a lab-type scope for less than $70. The completed unit contains only 11 transistors all mounted on a single printed circuit board. It is only 8" high by 12" deep, and weighs less than 10 lbs. This simplicity has been obtained by keeping the frequency response and sensitivity of the scope relatively low (although both are quite adequate for normal use), and by the use of a novel unijunction sweep circuit. This last feature deserves a special explanation.

In a conventional recurrent sweep scope, the signal which moves the beam across the screen can vary in frequency by perhaps 10% to accommodate changes in signal frequency — see Fig. 1(a). The ratio of signal frequency to sweep frequency must always be a whole number, or the trace will be an unstable jumble of lines. If the signal frequency should change by more than 10%, it becomes necessary to readjust the sweep frequency to maintain a stable display. This need for constant adjustment



Oscilloscope front view.



Inside top view of scope, showing sweep time switch S6 (upper left), main circuit board, and filter can C18.

makes it impossible to keep the horizontal sweep calibrated, so measurements of time and frequency cannot be made. The unijunction sweep can vary its frequency by a factor of about 2.5 in response to the input signal, so whole number ratios are always obtainable, and the display is stable for any signal frequency down to one half the sweep frequency, with never any need for adjustment. The result is a sweep which behaves very much like the laboratory scope's triggered sweep – Fig. 1(c) – with about one fifth the complexity. The difference is apparent only if you try to display a small portion of a cycle or a single shot phenomenon, such as a relay closing.

Our scope also includes a calibrated vertical amplifier and timebase, and triggering controls like the lab scope's, making it a versatile and accurate measuring instrument.

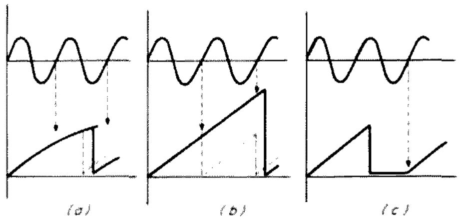


Fig. 1(a). The recurrent sweep generator can be restarted only about 10% sooner than full run-up time. The first triggering opportunity (downward arrow) may come too soon while the second comes too late, so each succeeding ramp shows the sine wave signal at a different horizontal position on the screen. Also, the ramp is usually curved, rather than linear, resulting in a distorted display.

Fig. 1(b). The unijunction sweep can be restarted after only 40% of a full run-up. Either the first or the second restart command could be obeyed, and either would result in a stable display. The ramp is perfectly linear.

Fig. 1(c). The lab scope uses triggered sweep – the ramp does not restart of itself, but waits for a triggering command derived from the displayed signal. The circuitry to achieve this is usually quite complex.

The circuit, which was designed to be absolutely as simple as possible, is shown in Fig. 2. It consists of dc coupled vertical and horizontal amplifiers, a sweep generator and four power supplies.

Vertical Amplifier

This is the "voltmeter" portion of the oscilloscope. It consists of an FET-bipolar Darlington pair, Q1-Q2, which provide a high input impedance and a low enough output impedance to drive the high gain, high voltage common base amplifier, Q3. Overall gain is about 150, variable by R4. C3 shunts extra signal to the Q3 input at high frequencies, thus extending the amplifier's frequency response to 600 kHz. D1 protects the gate of Q1 from accidental input overvoltages. The various values of RA and RB provide for division of the input voltage by factors from 1 to 400, giving voltage ranges of 0.1 V to 40 V per quarter inch division. CA and CB are required to compensate for stray capacitance in the resistors and switch wiring at high frequencies. CA is adjusted so that $X_{CA}/X_{CB} = R_A/R_B$ (i.e., the voltage division ratio of the capacitors equals that of the resistors). At frequencies above about 10 kHz, it is actually the capacitors and not the resistors which set the voltage division ratio.

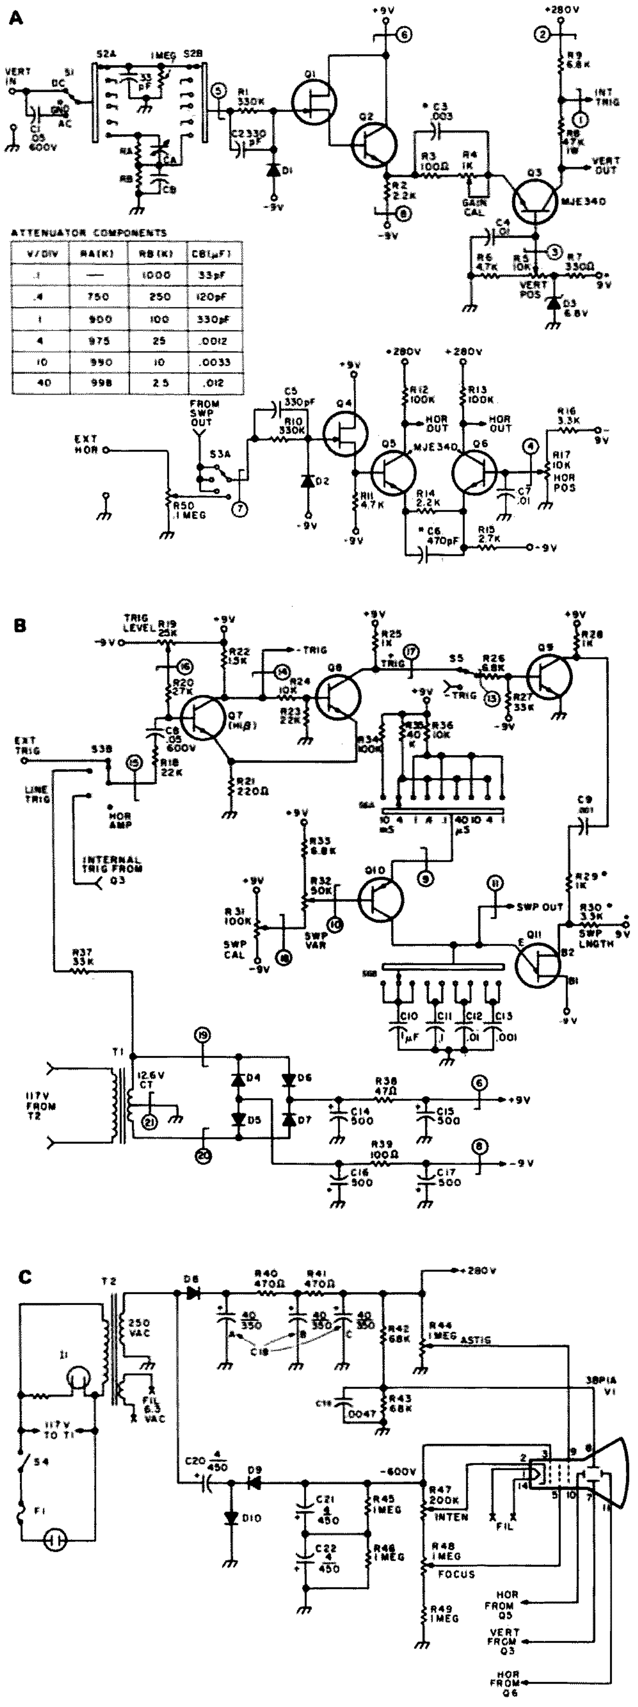
Horizontal Amplifier

This is normally driven by the sweep ramps, causing a left-to-right trace across the screen, but it may be driven by an external signal to obtain *Y vs. X* rather than *Y vs. time* graphs on the screen. Q4 is a source follower, providing a high input impedance while driving differential amplifier Q5-Q6. C6 is selected for optimum frequency response.

Sweep System

Q7 and Q8 comprise a Schmitt trigger, which produces square wave outputs regardless of the shape of the input triggering signal. These square waves are given extremely sharp corners by switching transistor Q9. C9 differentiates the square waves, giving a sharp spike at B2 of Q11 each time the Schmitt trigger switches. Q10 is a current source, which charges one of the timing capacitors, C10-C13. When the capacitor is charged by a constant current, the voltage across it rises at a constant rate, thus generating the required linear ramps. When the voltage from the emitter to B1 of the unijunction reaches approximately 75% of the B2-B1 voltage, the unijunction fires, E becomes momentarily a very low resistance path to B1, and the timing capacitor discharges very quickly.

Synchronization of the sweep ramps to the input signal is accomplished by the negative spikes from C9, which lower the B2-B1 voltage to slightly less than half its normal value for very



ATTENUATOR COMPONENTS

V/DIV	RA(K)	RB(K)	CB(μF)
.1	—	1000	33pF
.4	750	250	120pF

10	990	10	.0033
40	998	2.5	.012

Fig. 2. (a) Vertical and horizontal amplifiers for the simple oscilloscope. (b) Sweep system and low voltage power supplies. (c) High voltage power supplies and CRT circuit.

Vertical

Bandwidth — Dc to 600 kHz (-3 dB point)
Sensitivity — 0.1 V to 40 V per quarter inch division, calibrated in a 1-4-10 sequence
Input impedance — 1 megohm shunted by approximately 33 pF

Horizontal

Sweep — 1 usec to 10 ms per division, calibrated in a 1-4-10 sequence, variable to 500 ms per division
Trigger — 0.5 division p-p internal; 1 V p-p external; ac coupled
External Amp — Sensitivity continuously variable to 0.5 V per divison; bandwidth dc to 100 kHz

Table 1. Specifications.

short intervals. This gives the unijunction an opportunity to fire on command from the Schmitt trigger, provided that it has completed about 40% of a full run-up. R30 sets the full run-up ramp voltage, which should be about 2.5 times the voltage required for a full sweep of the screen. R29 sets the minimum ramp voltage, which should be just sufficient to drive the beam across the screen.

Power Supplies

Two full wave rectifiers followed by pi-section filters provide +9 V and -9 V to power the sweep system and low level amplifiers of the scope. The +280 V supply powers the output stages of the vertical and horizontal amplifiers, providing sufficient voltage to deflect the beam fully across the screen. A half wave voltage doubling supply produces -600 V which is applied to the cathode of the CRT. The overall accelerating potential from anode to cathode is, therefore, in the vicinity of +800 V.

Construction

Few of the components in the scope are critical and many substitutions are possible. The transistors may be nearly any silicon small signal types, with the exception that Q3, Q5, and Q6 must be rated at 300 V or more Vcer. The timing resistors and capacitors and the input voltage dividing resistors should be selected quite carefully, as these determine the ultimate accuracy of the instrument. It is not necessary that these components be the exact values specified, but only that they be in the same ratios. For example, if C10 is 6% high, C11-C13 should also be 6% high.

Many types of CRTs similar to the 3BP1 may be employed if the differences in base pin connections are noted. 3RP1s, 3EP1s, 3ACP11s and 3FP7s have been used with equal success, and there is nothing to prevent the use of 2-inch or 5-inch types. A number of flat-faced CRTs such as the 3RP1A and 3WP1 are available at somewhat higher cost for those who want to add the final professional touch to the scope.

The magnetic fields from the two power transformers will cause severe ripple on the CRT trace if special precautions are not taken. The transformers should be mounted with their windings in the plane of the CRT face so their magnetic lines of force travel with the electron beam rather than across it. The transformers should be mounted as far away from the CRT neck as possible, and, if available, sheets of mu-metal shielding should be placed under the transformers and around the CRT neck. The cleanest trace will be obtained if a full CRT shield can be obtained from one of the surplus houses.

All wiring involving vertical and sweep signals should be as short and direct as possible. In particular, the vertical input and vertical output wires should be kept away from each other and from other circuit wires. Note that the vertical input atten-

uator board is mounted directly behind the vertical sensitivity switch so that the wiring can be kept short.

Testing

It is suggested that the low voltage power supplies be wired to the circuit board first, with the high voltage transformer secondary left disconnected. The sweep circuit can then be tested without danger of shock or damage to the transistors from the high voltage supplies. Ironically, the best instrument for testing and troubleshooting the oscilloscope is another oscilloscope, but if none is available a VOM can be made to do. The output of the Schmitt trigger should switch from +2 to +9 V as the trigger level control is rotated. On the 10 ms/div range it should be possible to see the VOM follow the rise and fall of the sweep ramps if the sweep variable control is used to slow them down to a few sweeps per second. The outputs of the vertical and horizontal voltage followers (tops of R2 and R11 respectively) should rise and fall by about 1.2 V when a 1.5 V flashlight cell is connected in (first) positive, then negative polarity to the amplifier inputs.

Next, the +280 V supply should be connected and the vertical output should be checked for a swing from +75 to +250 V as the vertical position control is rotated. The two horizontal outputs should swing from +100 to +200 V, one going up as the other goes down, when the horizontal position control is rotated. If the two horizontal output voltages do not become equal at about +150 V, it may be necessary to alter the value of R15 to achieve proper balance. Finally, the -600 V supply can be connected and an attempt can be made to get a trace on the CRT.

Calibration

After the trace is focused and aligned, R30 can be selected to provide a maximum trace length of about 2.5 times the CRT width. Then R29 is selected to make the minimum length equal to the CRT width. These values depend on the characteristics of Q11. The trace length is changed from maximum to minimum simply by changing the frequency of the observed signal, or by adjusting the sweep variable control.

The vertical gain is set by adjusting R4 for a 3.9 division shift in the trace when a fresh flashlight battery (1.55 V) is connected with the scope on the 0.4 V/div scale. Next, a 1 kHz square wave is displayed and the five CA trimmers are adjusted for the cleanest display with no rounding or overshoot of the square wave corners. A square wave of about 50 kHz is then displayed and C3 is selected to make the corners of the wave as square and as sharp as possible without overshoot. Then a 10 kHz square wave is applied at the external horizontal input and C6 is selected so that the display consists of two sharply defined points at the left and right of the screen (the points will be elongated horizontally if the value of C6 is wrong). Finally, a 60 Hz ac signal is displayed (the one from the scope's own 12.6 V transformer will do nicely), and the sweep calibrate control is set so that one full cycle

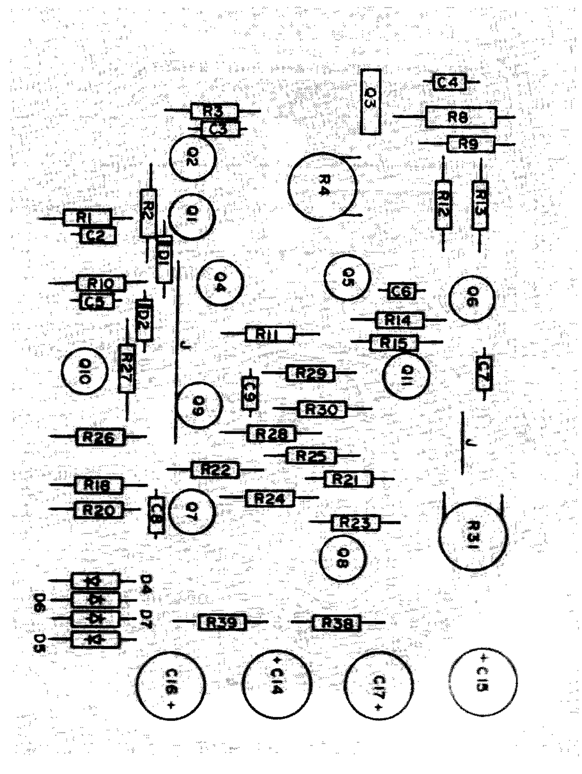

Fig. 3. Component placement on the main circuit board, top view. Note the two jumper wires, J.

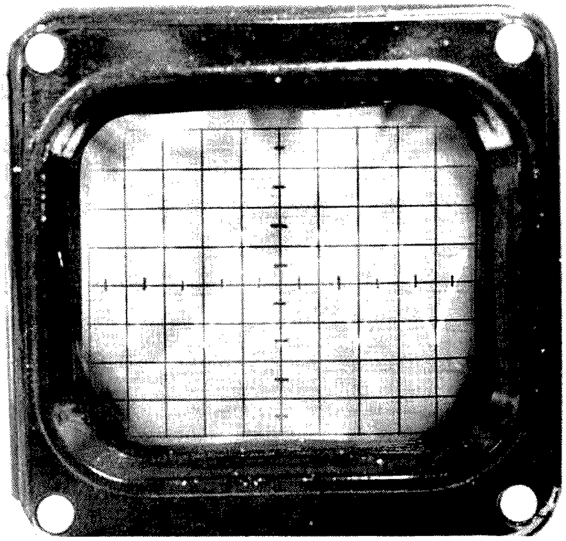

Linearity of trace is demonstrated by this photo of a 5 kHz triangle wave on the 0.1 ms/div range.

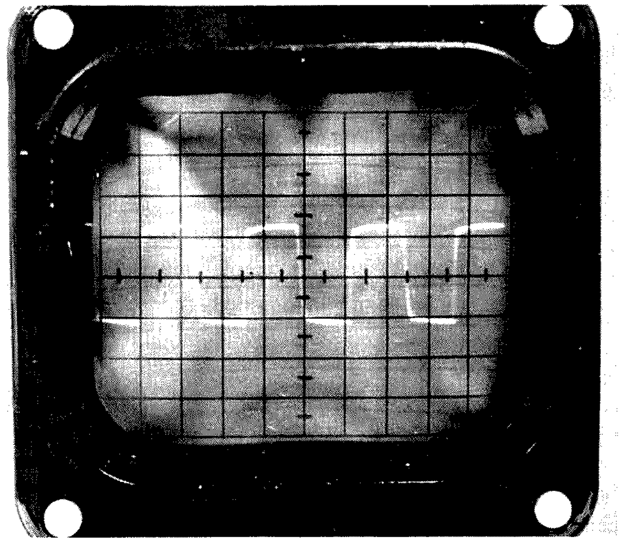

Photo of a 100 kHz square wave taken on the 4 usec/div range shows clean high frequency response and good calibration accuracy.

(16.7 ms) occupies 4.2 divisions on the 4 ms/div range. ■

Parts List

C1, C8 – 0.05 uF, 600 V disc capacitor
C2, C5 – 330 pF disc capacitor
C3 – Select for best vertical frequency response
C4, C7 – 0.01 uF disc capacitor
C6 – Select for best horizontal frequency response
C9 – 0.001 uF disc capacitor
C10 – 1 uF, 50 V mylar capacitor
C11 – 0.1 uF, 50 V mylar capacitor
C12 – 0.01 uF mylar capacitor
C13 – 0.001 uF mylar capacitor
C14-C17 – 500 uF, 25 V vertical mount electrolytic capacitor
C18 – 40 + 40 + 40 uF, 450 V three section can electrolytic
C19 – 0.0047 uF, 500 V disc capacitor
C20-C22 – 4 uF, 450 V electrolytic capacitor
CA (0.4-40 V scales) – 100 pF miniature compression trimmer capacitor, total of 5 required
CB – 0.1 V scale: 33 pF disc; 0.4 V scale: 120 pF disc; 1 V scale: 330 pF disc; 4 V scale: 0.0012 uF disc; 10 V scale: 0.0033 uF disc; 40 V scale: 0.012 uF disc
D1-D2 – silicon signal diode, 1N914 or similar
D3 – 6.8 V, ½ Watt zener diode (HEP Z0215 or equivalent)
D4-D7 – 100 PIV rectifier (HEP R0051 or similar)
D8-D10 – 1000 PIV rectifier (HEP R0056 or similar)
F1 – ½ A slow blow fuse
I1 – 117 V pilot lamp assembly (NE-2 bulb with 68k resistor)
Q1, Q4 – 2N3819 N-channel junction FET
Q2, Q7, Q8, Q9 – 2N3569 Si NPN transistor (or similar)
Q3, Q5, Q6 – MJE 340, 2N3440, or similar 300 V 1 W NPN transistor
Q10 – 2N3638 Si PNP transistor (or similar)
Q11 – 2N4891, HEP 310, or similar unijunction transistor
R1, R10 – 330,000 Ohm, ½ Watt resistor
R2, R14 – 2200 Ohm, ½ Watt resistor
R3, R39 – 100 Ohm, ½ Watt resistor
R4 – 1000 Ohm, ¼ Watt trimmer potentiometer
R5, R17 – 10,000 Ohm, linear taper potentiometer
R6, R11 – 4700 Ohm, ½ Watt resistor
R7 – 330 Ohm, ½ Watt resistor
R8 – 47,000 Ohm, 2 Watt resistor
R9, R26, R33 – 6800 Ohm, ½ Watt resistor
R12, R13 – 100,000 Ohm, ½ Watt resistor
R15 – 2700 Ohm, ½ Watt resistor
R16 – 3300 Ohm, ½ Watt resistor
R18, R23 – 22,000 Ohm, ½ Watt resistor
R19 – 25,000 Ohm, linear taper potentiometer
R20 – 27,000 Ohm, ½ Watt resistor
R21 – 220 Ohm, ½ Watt resistor
R22 – 1500 Ohm, ½ Watt resistor
R24 – 10,000 Ohm, ½ Watt resistor

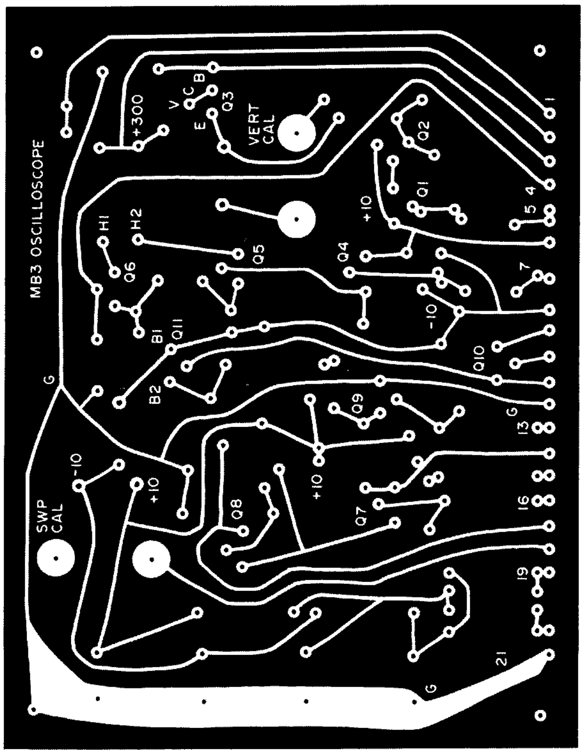

Fig. 4. Printed circuit artwork for the main board, bottom view.

Ham Help

I have a request for Ham Help. I need a service manual, or at least a schematic and specifications, for a Beckman Instruments electronic counter, Model 6020.

Blase J. Furfaro W7ISJ
10332 Camino De La Placita
Tucson AZ 85710

I'm looking for somebody who would help me in obtaining an amateur ticket. I am open for advice and help. I was hoping that someone could offer some type of course of study for me and when problems would arise I could contact him for help.

Peter Osroff
2442 East 26th Street
Brooklyn NY 11235
(212)-646-7757

I would appreciate any help in locating a schematic for a Singer portable TV, model number TV6U.

Would also appreciate schematics for BC-779 receiver and ART-13 transmitter.

Your magazine improves with each issue.

Harold D. Donaldson
8850 Phoenix Ave.
Fair Oaks CA 95628

I would appreciate some help in designing a communications device similar to the wireless broadcasters that seemed to be popular 10 or more years ago.

I am working with a group of hobbyists in putting on a large convention shortly. One of the major problems in managing a large convention is the communications area. We need to be able to contact key people immediately in emergencies. And, since this is a hobby group, the device should be cheap.

A base transmitter broadcasting an AM or FM signal through the hotel's 110 V power lines would serve adequately, since all that is needed to receive it would be a cheap pocket radio. A CB set might work, but the interference from competing stations is excessive. A simple wireless broadcaster using the 110 V line as a large antenna would seem easiest and cheapest.

However, circuits for such devices seem to have disappeared (or are no longer popular). Any help in design, suggesting references, etc., would be much appreciated.

LETTERS

from page 19

don't like is the way they are going about it.

The only mention they make of this petition is in the Executive Committee Minutes, which few hams will actually read. This appears in a short paragraph on page 62 of the August *QST*, for those who might be interested.

I can only say that I am going to take some action on this. I will be writing to the FCC with my own comments on Docket 20282. I hope other hams and Novices-to-be will do the same. Wayne, since you agree with me according to your editorial, I hope you will also act. Let's nip this in the bud now.

Already I am getting involved in the politics of ham radio. I was licensed first as WN3FNT back in 1966. I was again licensed as WA3JDT/WB8FAR in 1967. I gave up ham radio to complete a degree in electrical engineering. I now want to return, and I see that the ARRL is again dividing ham radio into a class system. I don't like it. They are positive on Docket 20282 — yet are secretly trying to have it amended. This infuriates me very much.

Thanks for listening to me, and I hope some positive action can be taken.

Bob Hajdak
Youngstown OH

BOON

One of the big kicks that I get out of reading *73 Magazine* is your editorials. I do not agree with you all of the time and do agree with you some of the time, but I enjoy any controversy or debate on ham radio or the problems with frequency allotments and so forth.

The main reason for this letter is this: *I like CB radio* and I think that it is a great thing on the whole and am not going to let it get run down by some know-it-all amateur radio operators. I have had a CB license since 1961 and have been a licensed ham operator since 1962. I have sold and serviced CB sets since that time and had a 2nd phone commercial since that time, so I do have enough knowledge about it to be heard.

CB radio has emerged, in the last five years, to be a very strong system for emergencies on a local basis, and, recently, as a terrific extension of the eyes and ears of our law enforcement people. I can say that it is a boon to these people. After all, the quickest way to apprehend a criminal or thief is with the *cooperation* of the general public, and, with the advent of some very good organizations, such as REACT and some other fine groups, it has come to pass that we have an excellent and *speedy* means to inform, locate, advise and operate in a saner manner than ever before. I am glad to note that you have decided to tap the biggest reservoir of potential hams that exists today. An ardent CBer can be converted to an ardent ham, but not by slamming, ridiculing or looking down one's nose at him.

Now, as to the holier-than-thou attitude that *some* hams have, it is a slam to the whole fraternity to have him expound on the lousy CB activities. If *he* didn't pass his code test and/or exam, he would be the most skip and yakker worker in the CB group. There are a majority of fine CB personalities who would make a lot better hams than some whom I have heard on the ham bands. I have heard some stuff that makes me feel ashamed that I belong to this group, and no doubt the same goes for the majority of CBers.

So, in closing this tirade, let me say quit knocking CB and quit this I'm-better-than-you attitude, before we alienate the biggest group of potential hams available.

One more thing: I don't care a whit about microprocessors and fancy ICs and some of the stuff that you have in your magazine, but I tolerate it because it probably means something to the next guy, so I am willing to tolerate it and consider *73* and *QST* two of my favorite mags. I would not drop *QST* for the world either. So I am willing to fight for both of you . . .

Get on Six with Surplus

--the el cheapo RT-70 is a natural

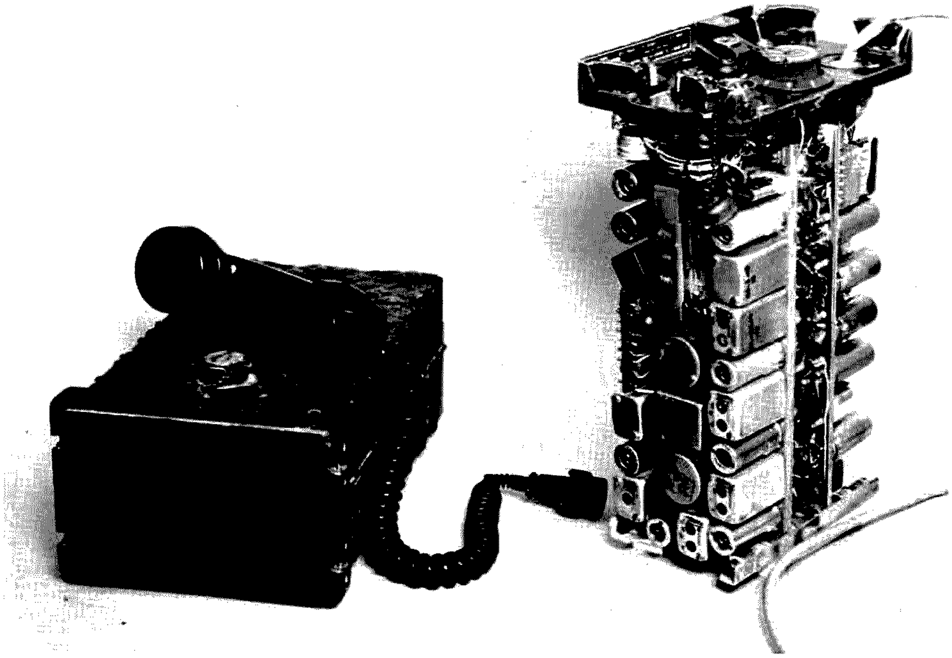
The finished RT-70 modification ready for installation. Its small size and minimal power consumption make it ideal for mobile use, but for serious work you will need an "afterburner."

In recent months a large number of RT-70 transceivers have appeared on the surplus market at prices from $15 to $25. These transceivers are designed for the frequency band from 47 to 58.4 MHz and therefore completely straddle the 6 meter ham band. To find a surplus transceiver that doesn't require extensive changes to operate on a ham band, and is simultaneously cheap, is a real achievement that many hams would take advantage of if they knew for sure what the conversion entailed.

The RT-70 is an FM transceiver covering the entire 6 meter band in continuous tuning, and transmitting at 500 mW output. The receiver section is a very good unit as is and will operate alongside the best of them without modification. The transmitter section is equally good, but several peripheral modifications will make it more convenient to use.

The first thing that is noticed when an RT-70 is

first fired up with its original microphone is that the audio quality is unbelievably lousy in that it won't modulate at all. Apparently years ago the carbon buttons were good but they have now deteriorated, because even the "new" buttons that I bought for 3 for $2.00, still packed in a hermetically sealed package, failed to remedy the situation. Fortunately this problem is easily solved. A standard telephone handset can be used as the microphone by placing a resistor across the button to decrease the sensitivity. Without the resistor you can stand across the room from the handset and have enough audio to modulate the transmitter. The resistor value has to be individually selected according to the handset used. Mine required a 27 Ohm resistor. If you can get a handset with push-button in the palm you have a fine TR switch built-in.



Left side and bottom view of the RT-70, showing the "Tank, Field, Veh" switch, S101, on the left side, in the "Veh" position. Look closely, just below the crystal Y-102, to see the regulator chip installation as described in the text.

Since some of the RT-70s being sold come without schematics, I will include partial schematics to illustrate the hook-ups. Fig. 1 shows the audio plug and connections to the handset. Place the resistor inside the handset on the terminals of the carbon button itself. Later in this article, I will show how to add a switch to turn off the earphone in the handset for speaker operation. Note that in most handsets the ground lead from microphone, earphone and TR switch are common and a single wire. This wire can connect to either pin H, pin E or pin B as all are grounded inside the set.

Finding audio plugs for the TR-70 is not as hard as finding power plugs; therefore, I have elected to modify the power input to use a piece of five conductor cable that can have any type of connector you like mounted on the outboard end. The modification is easy and works fine. Take a 5/16" drill and drill out the center of the present connector. Push the end of your 5 conductor cable through this hole, tie a knot in it and connect the five wires as follows (see Fig.2):

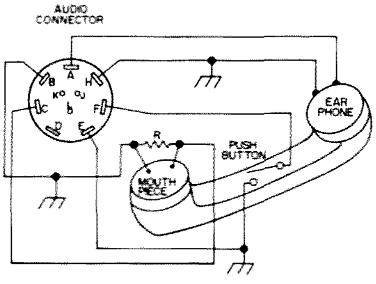


Fig. 1. Audio plug connections.

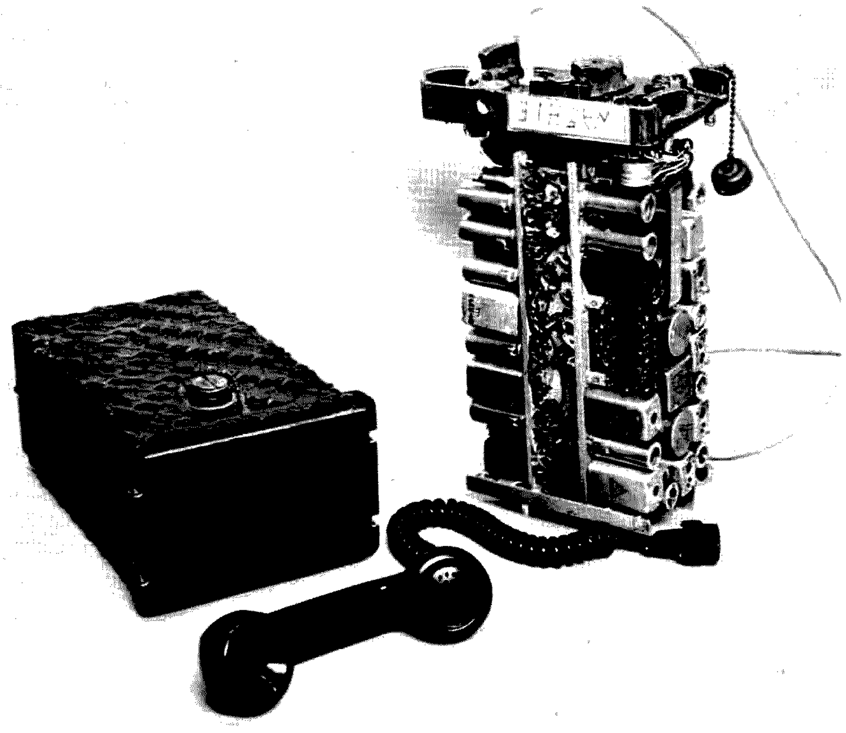
Connect the red one (if you have a red one) to pin J for the 90 V dc input. Next, connect the black one (again, note in parentheses above) to pin D for the ground. The remaining three wires are connected to pins B, F and A. But, prior to soldering to pin B, remove the wire already on that pin and place it on pin F along with the fourth wire in the cable. Now with the addition of a Fairchild 7806 regulator chip which will be described later, you can use the set with any voltage from 6 to 15 V dc. The Fairchild 7806 regulator chip is a 1 Amp 6 V regulator, all in one three head package with a mounting tab. The mounting tab is in most cases identical electrically to the center lead. Check your unit *first*, and if this is the case, the center lead can be cut off. Next, looking at the bottom of the chassis, you will see J1 mounted on the right side with two screws. Remove the nut on the screw toward the front of the chassis. Take a knife and scrape the protective coating from the chassis in a circle about 1/2" diameter around the screw. Now place the tab of the regulator over this screw so that the center lead of the regulator is pointing directly at the chassis mounting nut that holds the front panel on. This center lead may touch the nut, but no harm is done as this lead is grounded. The other two leads must be bent away from the chassis to avoid contact. Now replace the nut and tighten the regulator in place. This mounting will act as both ground and heatsink for the chip.

Now, using the diagram in Fig. 3, connect the input lead of the regulator to pin B on the power connector and the output lead to pin F of the power connector.

Now in operation, if you have a 6 V filament supply it can be connected to pin F (or



Left side and top view of the RT-70, showing the antenna connector on the end panel, and most of the tuning adjustments for the transmitter.

the cable conductor connected to pin F), while a filament supply of 8 to 15 V should be connected to pin B. Do not try to run a 6 V input through pin B and thus the regulator, as there is a 2 V drop in the chip which will result in a 4 V filament voltage, and the set will not operate on 4 volts. Also, do not connect both a 12 V and a 6 V supply simultaneously: You may blow the chip. And a final caution: Do not use ac filament voltages. The chip doesn't like ac, and neither do the filaments. Ac just will not work, so don't try it.

This regulator is an important addition, as the filament voltage is very critical for proper operation. A 5.5 V filament will cause a reduction of transmit power of 50%!

There is a switch, S101, on the left side of the receiver chassis. This switch is primarily used to compensate power supplies to hold the current drain constant during both transmit and receive modes. If correct drain is a problem, put it in the "field" position and then use a very well regulated 90 V supply capable of regulating from 30 mA to 80 mA. If on the other hand you have a good supply of 90 mA at anything from 90 V to 120 V dc, you can put the switch in the "Veh" position and use a dropping resistor to drop the voltage to 90 V. I used a surplus Sorensen power supply with an output of +107 V and a dropping resistor of 200 Ohms. The dropping resistor is calculated using the formulas in Table 1, and then adjusted to get what you want using a voltmeter.

I finally used a 200 Ohm 3 Watt resistor. Since the switch S101 is in "Veh" position the current remains nearly constant and the drop on the resistor remains constant.

The final three modifications I will describe are primarily convenience mods and not absolutely needed. The set will now run having made the modifications already described. Remember, FM on 6 meters is allowed only on the upper portion of the band. You can set the "preset" stops to mark the band edges, or use one of them for the local frequency.

If you use the set mobile, you will need a dial light. The one in the set is a 331 and is useless. Remove the bulb and replace it with a 328; then, in order to get the correct voltage on the tube, "short" out R-206. R-206 is mounted on the back wafer of the "Cal, Ant" switch, S-202, on the front panel. The resistor can be identified by its code, as it is an 82 Ohm resistor. Merely solder a piece of wire across it and your dial light is ready.

This modification is a matter of preference, but if you are to make the next modification, this one precedes it. The present antenna connection is on the front panel. I like mine on the back, so I moved it back. Remove the BNC connector and mount it on the chassis on the right side just above V1-1, in the aluminum web that supports the chassis mounting screws (see Fig. 4). Then drill a 3/8" hole in the cover so that when the set is in the cover the BNC antenna connector protrudes through the back. Now, using a miniature 50 Ohm coax such as RG-188A/U, connect the new antenna connector to the feedthrough originally connected to the front panel

R = E/I, where I is the current required to operate the unit (approximately .079 Amps) and E is the voltage of the power supply less 90 V.

Example: 107 – 90 = 17 volts = E

R = 17/.079 = 215 Ohms

P = E x I

Example: P = 17 x .079 = 1.3 Watts

Table 1.

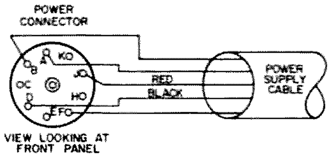


Fig. 2. Power cable connections.

connection. The shield should be grounded at both ends and placed in the channel runway along the housing of C-10.

Now, using the hole the original antenna connector came out of, put a single pole, single throw toggle switch in the front panel. Remove the red wire from pin A on the audio connector and connect it to one of the switch contacts; connect the other contact to pin A. Now you can disable the earphone in the handset to allow more volume in the speaker for monitoring when you are across the room, or for use when others in the car or shack want to hear both sides of the conversation, without blowing your ears off with the handset!

There are two further modifications that are possible on the RT-70. However, these are specialty items, and I won't go into great detail on them.

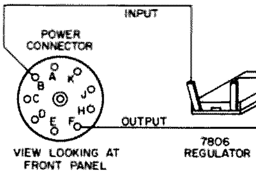

Fig. 3. Addition of regulator.

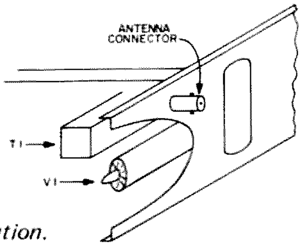

Fig. 4. New antenna connector location.

First, since this is an FM transmitter, a "cheap and dirty" amplifier can be placed on the output using a TR switch and rf power transistor to achieve 5 Watts or so in one stage.

Secondly, the RT-70 is ideally designed to use on a repeater. Since the transmit frequency is the sum of the variable local oscillator in the receiver and a 15 MHz transmitter oscillator, a change in the frequency of the 15 MHz oscillator allows the transmitter to be separately tuned. To operate on a repeater, it is only necessary to change the crystal in the 15 MHz oscillator/*doubler* (the crystal is 7.5 MHz– bear this in mind when calculating the transmit/receiver offset). Thus you will have a transmitter that tracks the receiver, offset from the receiver by a previously determined frequency difference.

Final notes: All these modifications work equally as well on the RT-70 as on the RT-70A, but, in selecting the unit, try to get an RT-70A. They usually are newer and in better condition. Second, don't pay extra for the 1 MHz crystal in the calibrator unless it is real cheap. Some places con you for $5.00 and you don't really need it at any price! It is nice for tuning up, but not at $5.00. And finally, try to get a manual. They are worth the price if available. The manual describes a complete tuning and maintenance procedure, as well as the equipment. It is one of the best equipment manuals I have ever seen.

If you can think of any other mods that would be helpful I would like to hear from you, and I will keep a file on any "new" mods that I will trade for your suggestions if you send an SASE. ■

The Beam Saver

-- rotor memory system

Robert E. Bloom W6YUY
8622 Rubio Avenue
Sepulveda CA 91343

This article is directed mainly at the ham who has had antenna rotator damage due to high velocity wind gusts. There is also information for anyone planning to purchase an antenna, tower, or rotor. In the main, I will present a modification for the Cornell Dubilier TR-44 antenna rotor that will automatically return the antenna to a pre-determined antenna azimuth or arc segment. This system is not limited to the TR-44, however.

I live in the San Fernando Valley of Southern California. During the months from February through April there are portions of this valley that have winds known as the Santa Anas. These can last for several days, carrying with them gusts from 20 to 85 knots. After each of these storms, one can drive down side streets and encounter a large number of twisted towers and beam antennas.

Many of the hams suffering damage could not believe this could happen to their structures, since they appeared robust enough to stand twice that wind velocity. Many hams purchase rotors, towers and antennas with hearsay information as to their structural wind strength, while other hams use the overkill theory. A tower designed for an antenna wind resistance of 2.5 to 5.0 square feet at 100 mph can have the tower twisted like a corkscrew with gusts of less than 50 to 70 mph.

After reading some of the latest specs from C.D. on the TR-44 and Ham M-2 rotors, I was surprised to see that they are rated for only 2.5 square feet and 7.5 square feet respectively. In this light it appears that a large percentage of hams are overloading these units with stacked beams that can easily be rated for wind ratings of 15 to 20 square feet or more. My tower is an aluminum 40' self-supporting structure capable of sustaining a 100 mph wind while decked with a 5 square feet array less than 1.5' above the top of the tower. The rotator is a TR-44. The antenna is a 4 element widely spaced 15 meter beam with a 3" diameter boom. After the first 35 mph wind, I guyed the tower. A subsequent wind broke one of the guy lines. I am sure that if the motor had had a strong brake the tower would have torqued sufficiently to have snapped. I had believed the many hams who had advised me that the TR-44 gear ratio would prevent the antenna from turning during exceedingly high velocity winds. Besides, the rotor would not turn beyond the end stops. Well, my coax was wrapped 5 times around the chrome molly mast post. Theoretically, the rotor cannot go beyond 360° because protrusions built into the casting come into contact with a hard drawn steel lever made of angled steel in the shape of a U channel. This strikes end stops, which are also built into the stationary part of the casting. I do not know how many pounds or tons of torque was created by the wind, but this piece of steel looked like it was on the losing end of a battle with a punch press.

With this background, we have arrived at the meat of the subject. How do we prevent this from reoccurring without having to replace everything with beefed up specs? A braking system had been contemplated at some length, but the prospect of having the tower torqued in half was quite evident. WA6MVP suggested the design of an electronic servo system with rubbery limits. The system in Fig. 1 is the result.

A breadboard model was devised to determine the circuit feasibility. A 500 Ω wirewound potentiometer and bench supplies were used to depicket the TR-44 rotor and control box. After being assured that the design was sound, most of the components were mounted on a 2¼" x 4½" universal PC board. Essentially, what is required are two 12 or 24 volt dc three pole double throw surplus relays, two inexpensive 741 op amps, or a single dual pack 747 IC, two 1N4004 diodes, two 10k Trimm potentiometers, three transistors (two used as relay driver switches and one as a B+ pass transistor), and one double pole double throw

toggle switch.

Let's first look at the Cornell Dubilier control unit schematic as redrawn for better understanding. The uncircled numbers are those that appear on the C.D. schematic. Those circled are those that appeared on the particular relays used in my unit (I found some new surplus, very small 4PDT 24 volt units at 75¢ each). The lever switch on the control unit essentially does two things: It applies line power to the power transformer primary only when moved to the left or right position, and it also applies 26 volts ac to one or the other split phased windings of the rotor motor. (One winding causes the motor to rotate counterclockwise, and other winding changes the direction to clockwise.) Incidentally, if you have had your rotor for some years and it only rotates with much persuasion, you most likely have a defective motor phasing capacitor. This capacitor is a nonpolar electrolytic. The electrolyte dries out after a time and the capacity is insufficient to change the phase of the current sufficiently. A good substitute is to purchase computer-grade capacitors of twice the capacity and connect them back to back. Remember that the 50 volt rating on the original capacitor has an ac rather than dc rating. As the ac voltage is a peak-to-peak, the formula becomes RMS x 2 x 1.44. However, if the capacitors are placed back to back, each of these would have a rating of 1.414 times the RMS value.

One of the first things that came to my attention on the C.D. unit was the amount of heat generated in the 300 Ω zener current limiting resistor. When the control unit is *on* for a prolonged period, both the 300 Ω resistor and zener will blister the fingers if touched. This current measures approximately 90 mA. The regulated 14 volts only supplies 1 mA to the

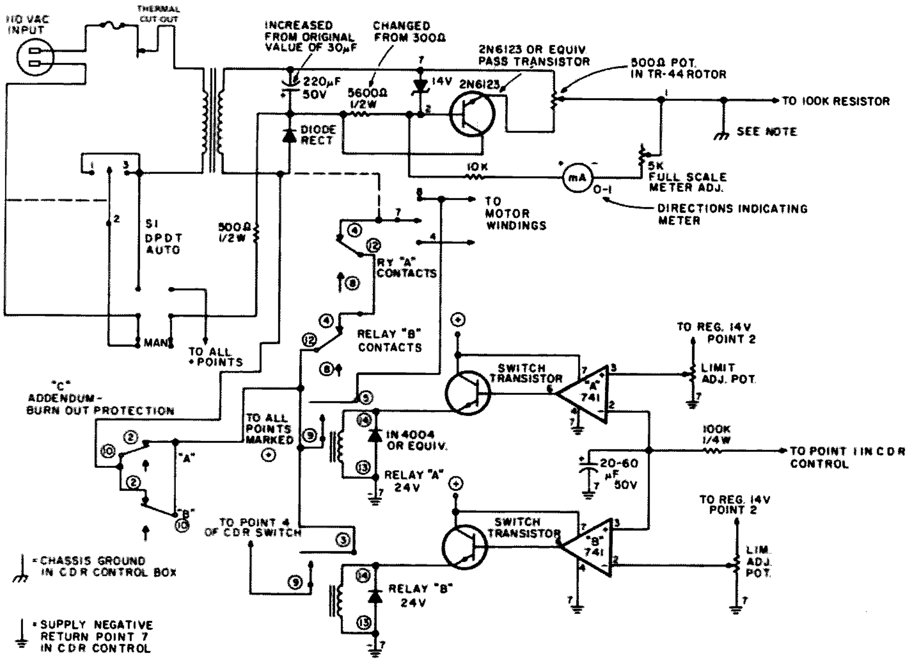

Fig. 1. S1 is shown in the manual position. Dashed lines represent wiring changes in the original circuitry. Relays A and B are shown in the de-energized position. Numbers not circled identify portions of the C. D. R. schematic. Numbers circled identify the terminal numbers on the particular relays used by author.

direction indicating meter, and about 30 mA to the 500 Ω pot located in the rotor housing, with the balance apparently used in biasing the zener. It isn't any wonder that the zener and its associated resistor get hot.

To operate the modified unit during a wind period, power must be applied to the transformer primary on a continuous basis. The zener and resistor are not rated to stand this kind of duty cycle. Therefore, a modification was incorporated to relieve this condition. A flat pack pass transistor, type 2N6123, was used. This transistor capability is like using a steamroller to crush a cinder. However, it is inexpensive, small and a heat sink is not required. This transistor has a minimum beta of 20 – thus the zener now only has to supply 1/20 of the current previously required. The 300 Ω resistor is now replaced with one of approximately 5.6k, and the zener still directly supplies the 1 mA maximum current to the azimuth indicating meter and biases the base of the pass transistor.

Notice that the 14 volt supply is a voltage source for the azimuth potentiometer. This pot acts as a variable voltage divider of zero to 14 volts; the 1 mA meter (1000 Ohms per volt) has a fixed 10 kΩ and variable 5 kΩ for full scale adjust. The 1 mA meter is set up to precisely indicate the source voltage.

Now let's look at the servo circuit. Note the two symbols for ground. This is not meant to confuse, but to identify two separate negative returns. The voltage negative return circuit of the control unit C.D. number "7" does not go to chassis ground, so do not make it a chassis ground when you make up your module. Note also that the only thing that goes to chassis ground in the control unit is the rotor of the azimuth pot. When this pot is in the most CCW position, its variable tap is at the "7" point or supply negative. In the opposite or clockwise position, point "2" is +14 volts. This variable ground potential point "1" is used as an offset voltage on pin 2 on op amp "A" and pin 3 on op amp "B." Note that this voltage is fed through a 100k resistor and junctions with a 20 uF capacitor. The capacitor takes time to build up and also takes time to drop its voltage. This makes for a hysteresis and allows the rotor to continue through and coast beyond the electrical limit. The outputs of the op amps are amplified by the emitter follower relay drivers A and B, which actuate either relay "A" or "B." Note that if 24 volt relays are used it may require about 18 volts for actuation. The relay energizes the proper motor winding and turns the antenna back to the initial point. You might ask why the motor doesn't just correct a few degrees and the relay drop out. The hysteresis introduced by the 20 uF and 100k resistor add a time delay, slowing down the buildup and drop-off of the op amp offset bias voltage. When you first try the unit, it is conceivable that the rotor will turn in the opposite

direction from that desired. In this case, just reverse the relay contact wires going to switch points 4 and 8. Circled relay contacts 4, 12 and 8 on both relays are connected in such a way as to prevent inadvertent manual control when SW-1 is in the automatic position. The manual position causes both relays to take a de-energized position and the control unit is now ready for conventional manual control.

For the initial adjustments, you must determine in which direction you want the antenna pointing. When in automatic, manually position the antenna to this position. Now determine the leeway on each side of this position. Set the antenna to the CCW limit point and adjust the appropriate limit potentiometer until its associated relay energizes. It might be well at this point to jumper the 100k resistor, as this shorts out the delay. The correct setting can thus be found more readily. Now manually move the antenna to the opposite limit point and adjust the second limit potentiometer for actuation of the second relay. With the servo main switch in the automatic position, the antenna should correct to the predetermined direction. Both relays are now de-energized. Switch contacts 4 and 12 of both relays should be in the position as shown in the schematic. Although the switch mode has been set for automatic, the manual control lever on the control head will respond, opening the 4 and 12 contacts on that relay. Manual control is lost until the servo is again balanced.

Protection circuit "C" was added to prevent damage to the rotor motor should a component fail. Connect contacts 2 and 10 as shown. This circuit prevents having motor driving voltage on both the motor phased windings, should a circuit failure close both relays simultaneously.

The entire servo section is built on a canned PC board or any board type you desire. The board size is approximately 2¼" x 4½". The board is then mounted in an aluminum box approximately 5" x 2½" x 2", depending on the relay size. You might want to set the control unit on top of the servo system, in which case you should use a box with length and width compatible with the control unit base. The 741s have 8 pins, so both can be plugged into one IC socket (unless the dual pack is used). The manual autoswitch is the only control on the box. Wires emanate from the back through a grommeted hole. If 12 V relays are used, the 500 Ω ½ W current limiting resistor can be increased in size, or two resistors in a voltage divider circuit can be employed.

Unfortunately, the transformer in the control head, although large and visibly husky, was not designed for continuous duty. Mine was so hot after about 5 hours that it was painful to touch. The overload circuit breaker, a temperature-activated device built right into the transformer, did not cut out. The secondary winding is of very heavy wire, but the primary saturates the core while only loading about 80 or 90 mA. The replacement transformer I used is a 24 volt 2 Amp unit normally used to operate a latching relay in a garage door operator. This transformer is less than three fourths the size of the one in the control unit — yet is only slightly warm after a 24 hour duty cycle. Fortunately, there are any number of units available from electronic surplus houses throughout the country.

The prolonged detail of this article is intended for the less technical ham. The more technical ham may just need the schematic diagram.

My thanks to Doren Rozenthal WA6MVP for his suggestions and assistance. ■

Updated Universal Frequency Generator

--extremely versatile test unit

The original article on the "Poor Man's Universal Frequency Generator" appeared in *73* for July, 1974. It has generated a great deal of reader response and it was considered worthwhile to review the instrument again and see if it could't be made even more reliable and versatile.

Basically, the generator is a collection of IC oscillators and dividers that can generate square waves from the HF range all the way down to the sub-audible AF range and can generate markers all the way into the VHF range. There is nothing sophisticated about the generator, and some of its function can be performed today by more advanced ICs with even greater versatility. But, the generator is hard to beat as a simple straightforward device that can be built at a very low cost (none of the ICs costs more than $1.00, except for one optional $3.00 type). It makes an excellent little project for those who still haven't started to experiment with digital ICs.

The uses for the generator, as suggested in the original article, are about as versatile as those of a grid-dip oscillator. Also, like such an oscillator which is not a very advanced type of instrument today, one nonetheless always keeps on discovering new and handy uses for the instrument. The broad uses still include: frequency marker generation, generation of crystal-stability RF or AF square wave signals, crystal activity checker, range extension for present AF or RF generators and a divider chain to allow HF oscillator stability and calibration to be checked by a low frequency receiver for those who lack a counter.

The block diagram of the updated generator is shown in Fig. 1. It consists of a selectable oscillator section, a fixed string of divide by 10 stages, and two divider stages which can be switched in at various points along the divide by 10 stages. The first oscillator is a 1 MHz crystal-controlled stage. Improved circuitry has been used which ensures more stable oscillation with any good 1 MHz frequency standard crystal. An LED indicates that the stage is oscillating. The second oscillator stage can be used with any external crystal extending up to the low VHF range. An LED again indicates that the oscillator is working. The stage can be used as a simple crystal activity checker with the LED, or crystal frequencies can be used which will give some desired output when the oscillator is fed into the divider chain. The third stage, as in the original generator, is not really an oscillator stage in itself, but an oscillator input stage. It will accept any external sine or square wave input, condition it, and then apply it to the divider chain. The fourth oscillator stage, which is new, really increases the versatility of the generator. It is a square wave generator whose frequency can be controlled by an external capacitor only. By proper selection of this capacitor, frequencies from several Hz to several MHz can be generated. Thus, in combination with the divider chain, any desired frequency or marker can be generated. The fifth oscillator stage, which is optional, is similar to the fourth oscillator except that it is intended mainly for the entire HF range up to about 25 MHz. Its frequency of oscillation is also controlled by an external capacitor, but its main feature is that it is a

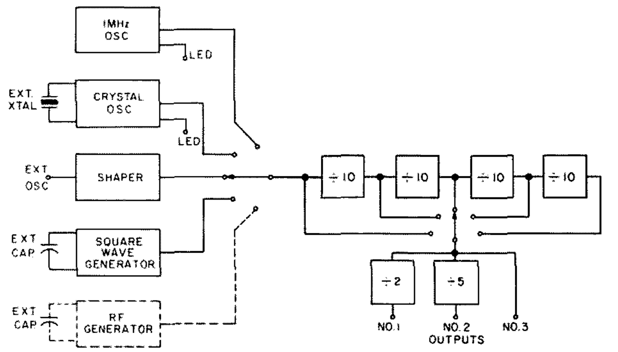

Fig. 1. Overall block diagram of the generator.

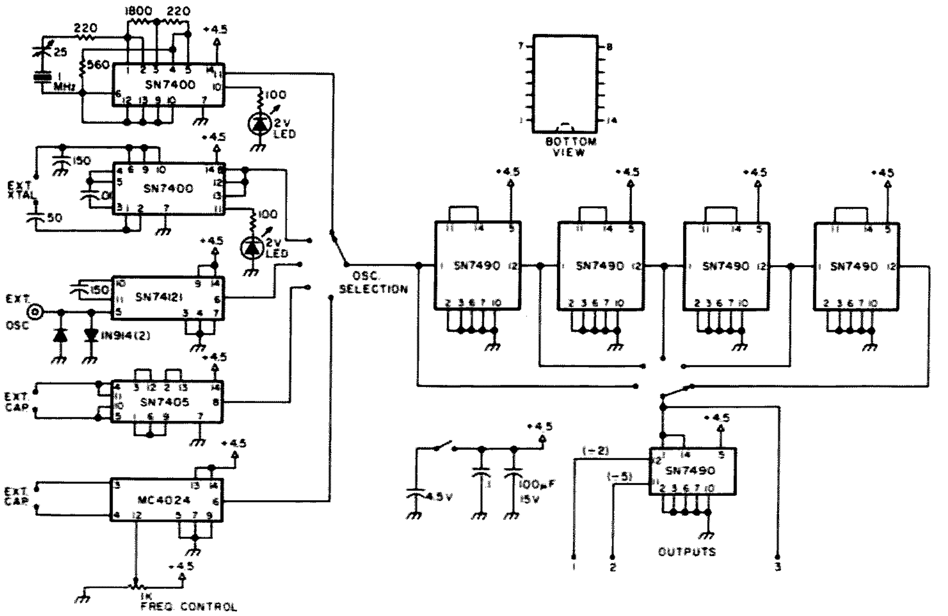

Fig. 2. Wiring diagram. Note that the divide by 5 and divide by 2 functions use only one SN7490. See text for some details on bypassing by each IC.

voltage controlled oscillator. By varying the voltage with a potentiometer to one section of this stage, a variable or sweep frequency output can be obtained.

The divider chain is a simple series of four divide by 10 stages. The outputs from a 1 MHz input will be at 100 kHz, 10 kHz, 1 kHz and 100 Hz. The stages are similar to those found in the timebase of any frequency counter or many crystal calibrators. The two divide by 2 and divide by 5 stages can be switched in along the divide by ten string. Using the 1 MHz oscillator input example again, the outputs of the divide by 2 stage will be 500 kHz, 50 kHz, 5 kHz, 500 Hz and 50 Hz. The outputs of the divide by 5 stage will be 200 kHz, 20 kHz, 2 kHz, 200 Hz and 20 Hz. This example may appear very obvious, but when dealing with inputs other than a simple 1 MHz one, it is important to list *all* the various output frequency possibilities to avoid confusion. Of course, looking the other way, that is, towards VHF marker frequencies, the above frequencies represent the intervals at which marker frequencies would appear since the output of the digital stages is a square wave with a very rich harmonic content.

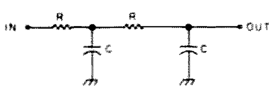
The actual circuit of the generator is shown in Fig. 2. Use is made, except for the optional fifth oscillator stage, of only simple SN7400 family ICs. The SN7400 1 MHz oscillator stage makes use of 2 of the gates for the oscillator itself, one for an output buffer, and one to drive the LED oscillator activity indicator. The oscillator can be beat against WWV for accurate calibration using the 25 pF trimmer. Do this by connecting the output of the oscillator, through a small coupling capacitor if necessary, to the antenna input of a receiver tuned to WWV on 5, 10, 15 MHz. During the 10 second tone pause on WWV, adjust the trimmer for zero beat. The second crystal oscillator will operate over a very wide range. The only component that may have to be changed with frequency to ensure stable oscillation is the 150 pF capacitor from one side of the crystal socket to ground. The 150 pF nominal value will operate satisfactorily with most HF crystals. The oscillator range can be extended higher or lower by making this capacitor have a value (in pF) equal approximately to 500 divided by the crystal frequency in MHz. Overtone as well as fundamental mode crystals will work.

The third oscillator, a SN7405, is a hex inverter which uses a single external feedback capacitor to produce a square wave output ranging from a few Hz to several MHz. The capacitor values needed will range from 300 uF to 30 pF. The output waveform is not exactly a square wave in the truest sense since the on and off times for each cycle are not exactly equal. Normally, this will not make any difference, but the situation can be corrected by connecting a 22k resistor from pin 4 to the supply voltage.

The fourth oscillator input stage has been found to function well and is left as originally shown. About a 1.5 to 2 volt input is required from any external sine or square wave generator to activate the multivibrator. The operation of the stage will be very obvious and even the output from a low voltage filament transformer through a current limiting resistor can be used to check that it is operative.

The fifth oscillator stage, a Motorola 4024, is a very interesting voltage controlled oscillator. Its circuit simplicity belies its very versatile usage. The operating frequency *range* of this oscillator (multivibrator) is controlled by the value of a single external capacitor connected between pins 3 and 4. The tuning or output *frequency* of the oscillator *within the range* established by the fixed external capacitor is determined by a variable 1 to 5 volt dc voltage applied to pin 12. For example, with a 430 pF capacitor between pins 3 and 4, the output frequency range as the voltage on pin 12 is varied between 1 and 5 volts is approximately 200 kHz to 1100 kHz. For a 100 pF capacitor, the range is 5 MHz to 25 MHz. The IC will actually operate up to 30 MHz with a bit of care as to lead dress, etc. The leads to the external frequency range determining capacitor should be kept as short as possible. Also, the ground leads and bypassing to the supply voltage pin should be short or the full frequency range of the oscillator may not be realized. Unlike the SN7400 series ICs which are widely available, one may have to look twice for a source of the MC4024. One source (at $3.00) is Circuit Specialists, P.O. Box 3047, Scottsdale AZ 85257.

The divide by 10 chain uses SN7490s in their conventional arrangement. Once the layout of a single stage has been determined, the rest need simply be duplicated. They can easily be wired on perforated board stock as can the other ICs in the



$$RC = \frac{10}{F 2\pi}$$

R in Ohms
C in Farads
F in Hertz

Fig. 3. Simple RC filter which will help round off square wave output so a quasi sine wave output can be obtained. Component values should be optimized using an oscilloscope if possible.

generator. The original article provided a simple enlarged view of simple perforated board wiring for SN7490 divide by ten units which is still valid.

The divide by 2 and divide by 5 stages are all actually contained in one SN7490 which sort of does double duty as a frequency divider.

The construction of the generator depends on individual taste. It can be constructed as an ac powered unit or as a portable unit. As an ac powered unit, a simple power supply using an LM309K regulator is recommended. My portable unit was constructed in an approximately 3" x 4" x 1¾" metal enclosure. The perforated board was just slightly smaller than 3" x 4" to fit the enclosure. Portable power can be supplied by a 4½ volt battery (Burgess 532 or equivalent) or 3 type C or D cells connected in series. There are two main bypassing details, however, which must be observed for good performance and which are *not* shown in Fig. 2 for sake of simplicity. *Each* IC must have a .1 uF disc capacitor going from its supply voltage terminal to ground. Also, a 100 to 500 uF/10 V electrolytic must be connected across the battery terminals for a portable unit.

The many uses of the generator have been considerably expanded by the update features described in this article. It can function as a highly accurate square wave frequency generator (down to fractions of a Hz) at any dividable frequency down from a crystal frequency reference. It can function as a highly accurate marker frequency generator in the HF or VHF range, depending on the crystal frequency reference used. It can produce basic frequencies or harmonic markers at any frequency up to VHF by means of its internal oscillator or by means of an external oscillator which is variable in frequency. It can serve as a crystal activity checker for almost all fundamental and overtone type crystals. The combination of having a crystal reference frequency oscillator available in combination with a variable AF or RF oscillator allows comparison to be made so one does not fall too far out of range within any variable frequency range.

A final word might be said about the output waveform of the generator. The output is a square waveform and hence quite rich in harmonic output. It cannot function as a pure, fundamental frequency sine wave generator and was never intended to do so. Reasonably good sine waves can be produced, however, at any output frequency by suitable RC filtering. The situation is very similar to that of filtering a sharply "clipped" audio signal before it is applied to a modulator stage in a transmitter. Fig. 3 provides the details of a 2 stage RC low pass filter which can be built for any AF to HF frequency to provide a reasonable sine wave output. Of course, LC filters will be better to get a pure sine wave, especially multi-section filters. The formulas for such LC low pass filters can be found in many reference texts on electronics. ■

Who, me? A Pioneer?

--some fantastic frontiers are wide open

There hasn't been a better time in the last fifty years than right now for the lone experimenter to do big things. There are still new frontiers that need exploring and some of these need just what the ham has to offer. If you have an unlimited curiosity about things electronic, and if new ideas are a great adventure to you. now is your time – that is, if you would like to do some research on your own.

Several areas that we would like to suggest are in the little known region where functions of the mind, body, electronics, and even communications just seem to overlap and blend. It's a sort of gray area where life itself may some day be explained by the laws of electronics.

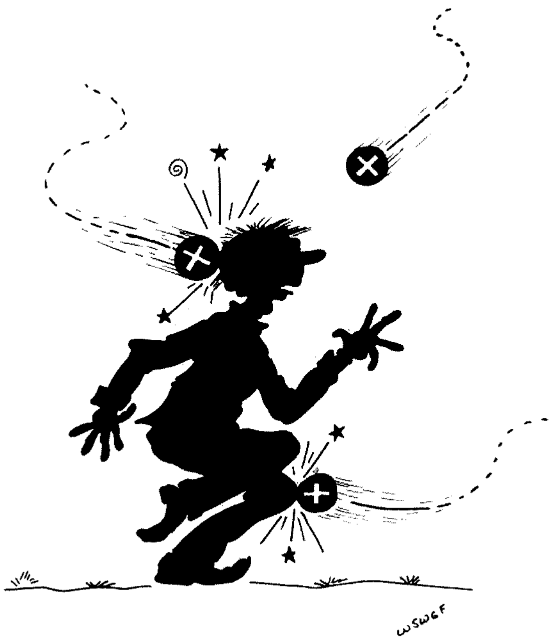
True, it's not exactly communications, so why bring it up in a ham magazine? Mostly because it's an exciting new world of electronics for the ham to experiment with and because people in ham radio have such a versatile reserve of skills which can help. It's work that can use talents ranging from those of simple measurements to advanced computer processing of complex data.

It is a world where the mystics rush in and which most scientists prefer to avoid. Both groups are making noises, but few are coming up with any usable answers. With luck, the rewards to the experimenter could be great, and the right answers could change our whole way of life.

In the recent mad dash of space age research we learned how to ask more questions than we are able to answer. New developments in instrumentation and methods of observation have shown us that a lot of things are happening that we just can't explain. With the recent decline in research money for the big labs, and most of all, with ultraconservatism increasing in established science, many of these questions may remain unanswered for a long time unless they are tackled by adventurous individuals. When these new horizons are finally explored, the groundwork will probably have been done in someone's back room, garage, or on the kitchen table. But whoever does it will need an open mind, a lot of courage, and a thick skin to survive. A basketful of junk will also help.

Many of the unanswered questions are very embarrassing to the established lab worker because they cannot be answered on the basis of

There are still new frontiers for the ham.



Headache? Sore joints? Maybe it's positive ions!

facts that we now know. Many of the questions have been swept under the rug just to avoid the unorthodox answers that seem certain to follow.

To compound the embarrassment, some of the observed phenomena are even related to folklore subjects. New measurement techniques verify that some old and odd effects really do exist, but it is not easy to explain why or how. To make things even more confusing, some of the more spectacular subjects have been seized by the occult and psychic groups and converted into mystical exhibits. Even some of the so-called researchers seem to be hung-up in a fantasy world.

One question needing attention happens to be related to communications. What is really happening when people think they are communicating with plants and flowers? It sounds crazy' but there's more to it than you may think. We have all seen the wild publicity-seeking stories of how plants think and can sense man's feelings, both good and bad. Even electronic devices are being used to show how plants express their likes, dislikes, and fears. We must admit that when a meter moves to full scale, something must be causing it. Perhaps it's time we found out what is happening.

And here is where you will need some of the courage we mentioned. The people who are riding the crest of publicity will be quite upset when you prove that their great new mystic display is based on natural phenomena which you can demonstrate. Many of the people in the field of science are also quite narrow-minded. They will avoid you because you have been flirting with the mystics. I have been down this road before, with Kirlian photography.

But somewhere a researcher is going to come up with some exciting new finds. Work in my own little lab leads me to believe that a few hams could put this whole plant dilemma in perspective. We will find that the phenomenon is based on sound principles, just like the night flying moth that uses microwave CW to communicate with its mate.

All things seem to indicate that the plant, when it reacts, is only acting as a detector and is sensing the changes in radiation from the human body. These changes are caused by the thoughts and emotions of the researcher or someone near. We already know that some of the signals are in the infrared spectrum, but who knows yet what other forms of transmissions are present? This could be important.

The plant, because its whole life process depends on forms of radiation, is simply acting as a transducer. Like the thermocouple, thermistor, or diode, it is merely converting a form of radiation into electrical impulses which can be read on ordinary instruments. The plant is not processing data and coming up with an opinion.

However, there is another exciting possibility if you care to speculate and crawl a little farther out on a limb. The electronics and chemistry of the plant may also be acting as a detector for forms of radiation which we do not know about yet. At this time, our thinking and theories are all built around electromagnetic radiation. Perhaps there are other forms of which we are not yet aware but which the right transducer could detect. There might be other natural transducers even better.

The well-known Dr. Rhine of Duke University fame proved in lab work that ESP involves a form of transmission that is neither time nor distance dependent. Perhaps it is time for some of us who specialize in detectors to try for some new answers. At this time there are at least six well-funded groups in the world trying to contact advanced civilizations in outer space. If people in outer space are as advanced as we would like to think they are, they may have long ago abandoned the use of slow, noisy, radio waves. Maybe we do need some new detectors. Perhaps your first far out space QSO will be using the old pine tree as a combined detector and antenna. Talk about the need for courage! You'd better be pretty well fortified when you tell your neighbor that you just received a message from Jupiter on the geranium. You may be lucky, though; he might just think you said

It says there's some distortion in your lower sideband.

germanium and are only half crazy.

But back to the serious business at hand; there is a lot of research needed in this area. We have found that certain plant leaves, even when removed from the plant, will give full scale readings on our instruments when a human hand is brought within four feet of the leaf. Just turning on a soldering gun across the room from the leaf will also produce full scale readings before the gun is hot enough to melt solder. A light beam on the leaf will do the same. But high background readings, even in a dark room, indicate that the leaf is also reacting to other signals. What are they? How about putting a leaf In a parabolic reflector? Where do we go from here? It's as wide open as ten meters in a high sunspot cycle.

Yes, this is unexplored territory, but there has been an occasional wanderer passing through. So don't be surprised if you find a few footprints as you travel along. Fifty years ago John L. Reinartz, one of the early all-time greats in ham radio (1XAM, later K6BJ), was interested in the electric currents generated by living plants.

There is no limit to what we may find now, with our new capabilities. All of the work with plants can be done with home-built electrometers and sensitive low frequency and dc voltmeters built from bargain ICs. It can be done on the kitchen table or in a corner of the garage.

Another bit of research needed is even closer to ham radio. It is in the field of atmospheric electricity, or potential gradient. There has been a lot of work done here but much more is needed. Needless to say, lightning has been a headache for hams from the early days. But lightning is probably the most publicized and least important part of the potential gradient story.

There is a voltage difference between the surface of the earth and the ionosphere of about 350,000 volts, with a continuous current of about 50,000 Amps at all times. This is distributed over the entire surface of the earth and at any given point the current is very small. However, the natural potential difference is vital to the balance of nature for the function of the human body and things that live above ground. One of the problems beginning to face us now is that with all of our electrical apparatus, power lines and such, we are destroying the original dc field. We are overriding it with pulsating ac fields which can have an adverse effect on both mind and body.

For a long time this idea was ridiculed by the scientific community. But just recently it was announced from Europe and verified by researchers in this country that people working in the vicinity of high tension power lines are developing health problems. This can also happen in the fields of other devices such as high power transmitters. Of course some of this work must be done by medics, but there is much that can be learned by the small worker.

The high level surges from power lines or other electrical equipment are suspected by some of being capable of even resetting biological time cycles. Dr. Ross Adey (WB6DEX) of the University of California School of Medicine has done some excellent work in this field.

It is known that altering the potential gradient within buildings can affect sleeping habits. In our own experiments we have found that restoring the voltage gradient in the home (artificially) can increase the ability to get a good night's sleep. It also increased the feeling of well being and the ability to think better during waking hours.

You don't have to be crazy – but you'll never convince anyone else.

In office experiments, returning the gradient to the normal values decreased work errors by 50% or more. This in turn brings up other questions. What does the HV supply in the TV do to the voltage gradient in the room? Is it good or bad? Perhaps its overall effects are worse than the x-rays we worry about? All of these things can be researched with instruments and power supplies that many hams can construct at little or no expense.

Still another of the interesting areas, which is somewhat related to potential gradient, is air ionization. An ion is just a particle that carries a charge. Of course they can be either positive or negative. The ions that we are interested in right now are air ions, or charged air particles. When the negative charges in the air that we breathe exceed the number of positive charges, we feel better, many respiratory ailments disappear, wounds heal faster, and all sorts of wonderful things happen. It's just one of those great days. Positive ions can cause the reverse, such as that old dopey, draggy feeling. Rheumatism, asthma, circulation, blood pressure, and all sorts of problems get worse. The medical effects of ions on life have been well researched by reliable labs in this country and in Europe. But that is just about where it has stopped. Perhaps one reason is that plenty of usable negative ions are hard to come by. And here is where the ham could really get involved – in the hardware. No one has seemed to come up with an easy way to generate negative ions without some unwanted side effects such as radiation, ozone, excess heat and the like.

As usual, the federal government has only made

matters more confused. A few fast-buck artists got into the field early and peddled some phony equipment. Now everyone must suffer because the Food and Drug Administration has made rules that severely limit work in this area. Like many other things that the FDA has done, much of it is without rhyme or reason. It is another case of bureaucratic sheepdogs chasing phantoms and barking "wolf." However, if you don't hang out your shingle you are on safe ground.

There are many other unexplored areas, like the Lakhovsky effect, for those who like the unknown. Lakhovsky was a Russian refugee scientist who demonstrated years ago that bursts of low level broadband rf power in the microwave region would cause malignant growths, on both man and plants, to dry up and disappear. No harm was suffered by the patients. He proved his point in large hospitals in both Europe and this country. But like so many such discoveries, it was a good demonstration and that is where it stopped. Lakhovsky was not an M.D.; he was an engineer. This ruled out any use of his discovery. To close the incident, such effects as he demonstrated were theoretically impossible and therefore did not exist.

These are only a few of the fields that are electronic-related and are ripe for research. They also offer the chance to be tarred and feathered by our progressive and advanced society. However, considering that ham radio is a hobby that cuts across all professions and businesses, there is probably no group with more contacts to call on for help or additional information. As usual, some of your best help might come from your local politician. If worse comes to worst, you might end up with a job bugging . . . plants. ■

LETTERS

from page 38

bands.

The good people at the Baltimore FCC are tired of seeing me come in, pay my four bucks, and then blow the code test time and time again. My copy is good at home, but as your ad says, the steely-eyed monsters at the candy factory scare hell out of me. No kidding! I'm a big boy now and I feel that your tape is the answer. I'm not afraid of the truth.

I know that you most likely get tired of reading idiotic letters like this one, but your editorials and magazine in general has been the uplift that I needed to rekindle my interest in ham radio. I thought that everything had to be technical and impersonal with no fun, as depicted in other magazines. I admire your straightforward approach to state what you think is right or wrong — whatever the subject. Keep it up — that's what our society needs more of.

John J. Dippel, Jr. WA3YPS
Baltimore MD

READ THE RULES

I have your latest magazine at hand with the cover copy, "Hey, CBers!"

I have been a Novice for about seven months now and have had quite a bit of "on the air experience." My question is, "Why should any CBer want to change to ham?" Every time I make a good contact with someone, there is always another station that comes right on without listening, and starts calling. I in return simply QRT because it isn't worth it to continually buck this sort of thing. At least the CBer asks for a break and goes to another channel for the QSO. He also thanks you for the break. The CBer that I am in contact with is courteous and interested only in good clean contacts and signals. He is interested in good relations, and is an addition to his community and the many other CBers.

As far as rules are concerned, I can find as many offenders on the "ham band" as I can find on the CB channels. I have heard deliberate jamming, obscene language, lack of courtesy, operators using their equipment wrongly, and even solicitation.

So my question remains. I believe also that, before bragging too much that, "I am a ham, not a CBer," some of them had better read the rules again.

SUCCESS

The Mount Airy VHF Radio Club (The Pack Rats) is pleased to announce that the Colombian moonbounce expedition was an unqualified success. We accomplished the following: 1) first 432 EME contact from South America; 2) first OSCAR 7 Mode "B" contacts from Colombia; 3) a total of 16 stations were worked on 432 EME, representing eight different countries; 4) there were approximately 75 OSCAR 7 Mode "B" contacts.

The station (HK1TL) was operated by the following individuals: Anthony Souza W3HMU, S. William Olson W3HQT, Walter Bohlman K3BPP, Elliott Weisman K3JJZ, Daniel Mitten WA3NFV, Socrates Martinez WB3AFY/HK1CWB, Bohlmar Aguilar WB3AOP/HK1AMW.

The trip was financed by the individuals listed, with assistance of the following: unidentified Pack Rat member, Mount Airy VHF Club treasury, Collins Radio, Northern California DX Association.

We deeply appreciate the South American coordination of HK1BYM, Dr. Atenogenes Blanco, and the complete support of the Area-2 Radio Club of Barranquilla, Colombia.

We would also like to acknowledge the stateside liaison work of W3KKN, Ernie Kenas, and W3TNP, Bertha Kenas. This liaison work was instrumental in developing new EME schedules. QSL via HK1TL, Box 169, Ottsville PA 18942.

STREAMING

Congratulations on the new format of *73*. It is a real nice magazine you are putting together. The pictures and diagrams look a lot better this way.

Our repeater, WR4AQR, is full of gadgets copied from *73*: I built the autopatch around an article printed in *73* a couple of years ago. I changed a few things around, like three digits to activate and three to deactivate, canceling activation if the digits are not pressed in less than four seconds, avoiding false triggering, time out limiting calls, activation of tape re-

The Shirt Pocket Touchtone

-- autopatch from your HT or car

This article describes a simple and inexpensive touchtone encoder which can be built within an hour or two and used with any FM rig for autopatch operations. Since the encoder is quite small, it is ideal for both mobile and portable work. When not in use, it can be concealed in an auto's glove box or carried in a shirt pocket. Connection to the FM rig may be acoustical or electrical as desired, thus permitting the pad to be swapped between several setups.

Front view of touchtone encoder. Unit fits comfortably in shirt pocket.

This little gem consists of a small "SME" touchtone generator manufactured by Data Signal, Inc., of Albany, Georgia, and any common, small transistor radio. The touchtone pad is mounted on the transistor radio, using its audio section for amplification. Output tones can then be fed into the mike of your FM rig. Data's inexpensive "SME" is sold in two parts: the printed circuit board tone generators and the keyboard proper. As several interchangeable keyboards are available, you can choose one which suits the particular transistor radio used.

Getting Started

First, select a touchtone

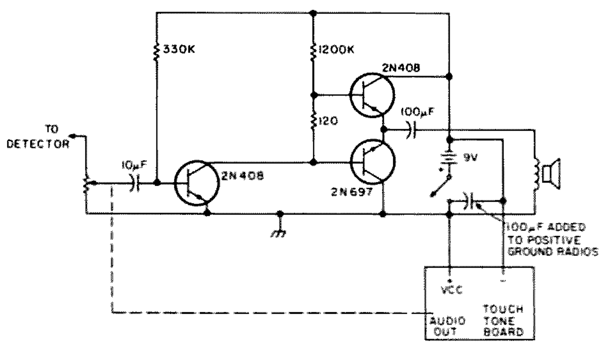

Fig. 1. Complementary-symmetry output of inexpensive transistor radio. Note use of 100 uF capacitor to facilitate mixing positive and negative ground circuits.

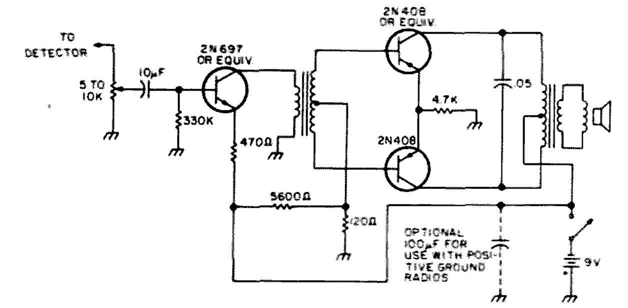

Fig. 2. Sample schematic of a push-pull output used in a transistor radio.

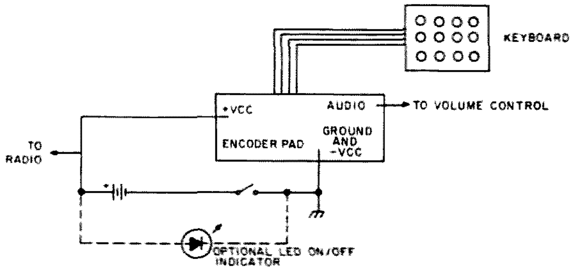

Fig. 3. Negative ground radio.

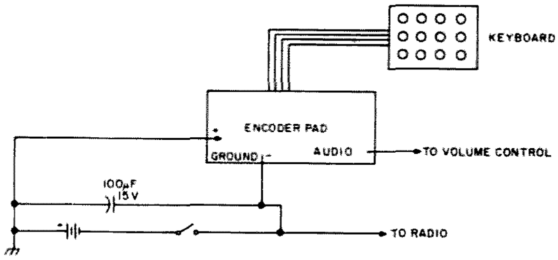

Fig. 4. Positive ground radio.

encoder and a small transistor radio which will look professional when mated together. Pick a radio with a straightforward audio circuit and negative ground (if possible). Make sure it has a long, flat loopstick antenna approximately the size of your encoder's printed circuit board. Most inexpensive radios use complementary-symmetry outputs similar to that shown in Fig. 1, while slightly more expensive radios use push-pull outputs similar to Fig. 2. Next, check out the radio's audio section when tones drive the isolated amplifier stage. This is best accomplished by connecting the encoder output to the wiper and one end of the volume control (you can also connect tones between the diode detector output side and ground, if the volume control method presents a problem). Clip lead jumpers are handy for this preliminary test.

Construction

If everything works properly, you are ready for the brutal part. Remove the radio's printed circuit board, and then detach the loopstick antenna and main tuning capacitor. Remove the tuning dial (if it wasn't removed along with the tuning capacitor) and any ornamentation covering the selected keyboard mounting area. Put the touchtone keyboard in place and mark the area which must be cut to allow proper fit (the keyboard's furnished paper template is ideal for this purpose). Now, carefully drill the necessary area to clear your keyboard's connectors. (This area can also be melted with a small, low wattage soldering iron.) I suggest that you make small oval connector openings, leaving the maximum amount of surface for pad support. After you become accustomed to working with plastic, you can move and reweld any printed circuit board supports removed during the previous drilling process. Next, drill four small holes for the pad corner studs and place a fine layer of cotton on the keyboard mounting surface. Now mount the pad, check to see that it isn't being bent or warped, and then lightly glue it in place.

After the glue dries, solder all connecting wires to the keyboard and tone generator board. Solder encoder ground and audio output wires to the radio volume control, and then reinstall the radio board while keeping everything intact and neat. The tone generator board can now be fitted into the loopstick antenna space. The final step involves connecting positive voltage to the encoder board. If you picked a negative ground radio, this is quite simple: just run leads to the *switched* nine volts, as illustrated in Fig. 3. If doubtful, use a VOM to find convenient take-off points and to make sure that low current isn't drawn while the unit is off (the SME doesn't draw current until a button is depressed). If you picked a positive ground radio, the encoder circuit will require grounding for ac (tones) but not for dc (nine volts). An arrangement which accomplishes this is shown in Fig. 4. The 100 uF capacitor passes tones while preventing dc from shorting the battery. Be sure the encoder and radio PC boards are not grounded together, and all will work fine.

The output level is adjustable with the radio's volume control. If your autopatch repeater is critical of tone amplitudes, just mark the exact tone level spot on the volume control knob.

Should you desire to electrically connect the encoder to a mobile rig and acoustically couple it to a handie-talkie, then make a small cable to use between the radio's earphone jack and your mobile FM rig. When using this method, best performance is realized by connecting the encoder output between ground and wiper of the FM rig's internal deviation potentiometer. This method eliminates any clipping or reshaping of tones that occur in the rig's audio section. (This modification is easily performed on gear like the TR-22. Reconnect speaker leads to bypass the front panel earphone jack, and then connect a wire from the deviation pot to the earphone jack "tip." Tape any exposed wires.)

Other Applications

Earlier, I suggested that you lightly glue the touchtone pad to the transistor radio. Should you later decide to mount this touchtone encoder onto a specific FM rig, cut the pad corner mounting studs and *carefully* work the pad loose (use fingernail polish remover if necessary). Cut connecting *wires* and remove both parts of encoder. Avoid resoldering to the pad — it's quite delicate. Now mount the complete works in your new rig.

Conclusion

During recent years, I have used several other touchtone encoders and they all had similar problems: They were inflexible and bulky. This little encoder is so small and handy that I can carry it anywhere, anytime. I think you, too, will enjoy owning and using such an interesting ham conversation piece. ■

Put Your Name in Lights

-- giant nixie message display

The Burroughs giant nixie B7971 readout is one of the most intriguing devices to appear on the surplus market. Simple, single message displays are easy to construct. (See Nov/Dec *73 Magazine*.) Using the nixies in a clock requires only a few more parts than the usual LED readout chronometers and is well worth the effort.

But casual thoughts on the subject of building a changing word sign conjured up visions of a complex, computer logic matrix, a project this old, middle-aged ham thought better left to the IC generation.

However, like many other conclusions reached without proper cogitation, this one had no basis in fact.

Unfortunately, keeping beans (and occasionally meat) on the table, gas in the Ford, and two jumps ahead of the utility company and Ma Bell's collection departments requires a bread and butter job. Mine happens to be in the sales field. A part of my duties includes setting up and manning a booth at various conventions. For the past year, each time I set up the booth and hung the same wrinkled banner used for the past ten years, I would think how attractive a nixie display sign would look. Then, further dreaming, I would picture in my mind a changing letter display with the product name alternating with a hard hitting sales message. The changing letters would *have* to attract attention.

So, finally, I began doodling, figuring out the words and combinations I would need, and how and when and which segments would need to light.

One key fact was immediately apparent: The lighted segments needed to form the two messages would be contained in three strings:

1. "A" Segments common to both sets of words and numerals.

2. "B" Other segments connected together, which, when added to the common segment string, would form the first message.

3. "C" The third string, when combined with the common segments only, would form the second message.

With this obvious and simple discovery, the complex job had now become commonplace. All that was necessary was to wire the segments that were common to both messages so that they would stay lighted at all times. Then, by switching on either of the other strings a message would be formed. A simple, single pole, double throw toggle action would complete the display.

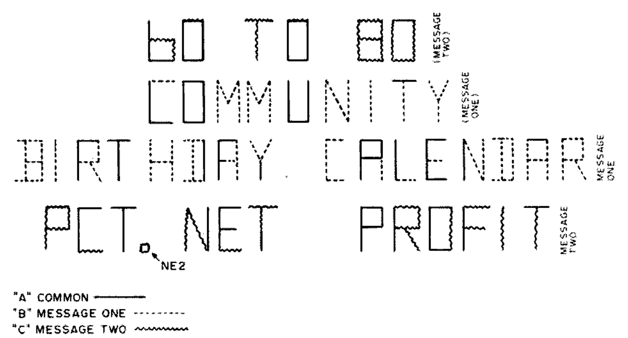

Fig. 1. Two center lines — first message. Top and bottom lines — second message. Only nixies in first message used to form second message. Two center lines change to form message shown here in top and bottom lines.

There were several ways this could be accomplished: mechanically, with a geared motor and cam; with tubes and a polar relay; or with switching transistors.

Resisting the temptation to revert to tubes, I turned to solid state. As usual, a persual of my available magazines turned up no information. So I started from scratch.

The 555 IC looked like the ideal timing device. Tying it to a flip flop (7476 or 7473) would give two positive voltages of opposite timing and selected duration. This voltage, I reasoned, could be used to turn on transistors in the negative leads of the nixie segment strings.

Actual construction of a

changing letter display of your choice is relatively easy. First, you must decide what you wish to say in each of the two messages. Then count the letters in the longest message. You will need this many B7971 nixie tubes and sockets.

(Let me say here that the article on simple displays in the Nov/Dec issue of *73* produced more reader correspondence than any article I've ever written for any magazine. Most wanted to know where to get the nixie tubes, which had been advertised in the May issue of *73*. At this writing, less than a week ago, I received tubes from Meshna, Lynn, Mass. A friend purchased six from Fair Radio Sales. All I can say is, watch the ads, and write to the surplus dealers.)

I found the easiest way to lay out the sign was to print the longest message in the center of a page, and the second message above (if a single line) or above and below (if a double line). See Fig. 1.

The next step was to code the letter segments. First I used a red Flair pen and drew (over the light pencil markings) all segments which would be common to both messages. Then the segments necessary to complete the first message in another color. And finally, the additional segments to complete the second message in the third color.

Once this task was completed, the sockets for the nixies could be arranged and mounted on the appropriate size sheet of plywood. If the sign contains two rows, the upper row of nixies should be mounted upside down. In this manner the sockets and wiring may be concealed by the cabinet frame. If you have bought the nixies with driver boards, use the aluminum brackets and sockets as removed from the boards.

The anode (pin 13) of each nixie is fed high voltage through an 800 to 1,000 Ohm resistor. (This resistor must be of a higher value if a higher voltage source is used.) All common segments are connected together and directly returned to the negative (-) terminal of the 150 V dc supply. The two other segment strings are tied together in a similar manner, but each of these strings terminates at a switching transistor. I used wire, the same colors as the sketch, which made it easy to correct mistakes. I also found it best to wire "live," with the voltage applied to the anodes, and with a test probe connected to ground. In this manner, a touch of the probe showed which segment was being wired.

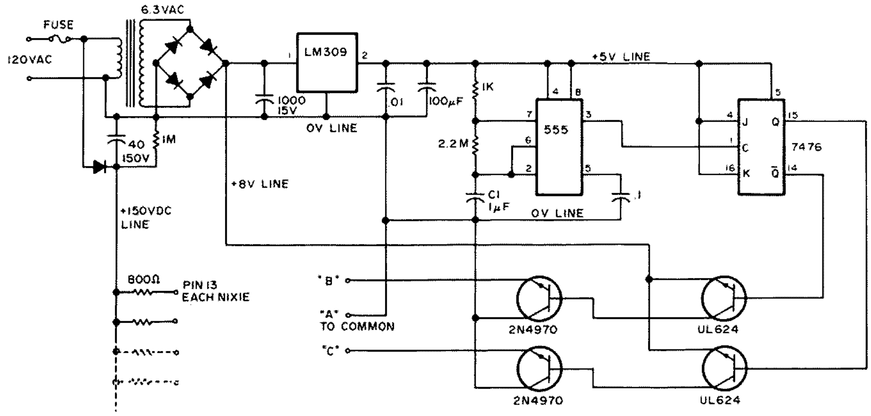

Fig. 2.

The power supply must provide two voltages, 5 V regulated, and 150 V dc. I used a half wave line voltage rectifier for the 150 volts. The low voltage supply is obtained from the rectified output of a small filament transformer and may be from 6.3 V to 12.6 V. I used a very small clock transformer giving 9 V ac. An LM309K provides the regulated 5 V.

The 555 circuit is standard. You may wish to change the 1 uF capacitor (C1) for a different display interval.

Only one half of the 7476 is used.

The only problem encountered was getting the right switching transistors for a clean on-off break so that no residual flicker remained on the turned off segments.

First, I tried driving the switching transistors directly with the 7476, but spikes coming from the high voltage nixie supply were too much for the 5 V IC.

All four driver transistors are NPN, and all are small, low wattage. The actual switching transistors used are 2N4970s (300 V, NPN). The isolation transistors are old UL624s, also NPNs removed from the surplus nixie boards.

A scope is not needed, as all measurements needed may be made with a VOM. Of course, when the power supply is complete, be sure the LM309 is doing its job before applying power to the 7476. If the 555 stage is working properly, you will read, at pin 3, approximately +4 volts, turned on, then off. If you use the 7476, the same voltage will be read at pins 14 and 15 (pins 5 and 6 with the 7473).

A printed circuit board would, of course, be the ideal way to wire the power supply and timer circuits. However, since this was a one of a kind project, I hand wired, soldering directly to the IC pins. A couple of hints for this type of construction: Use one strand from a small stranded wire to make the connections to the IC pins. Drill small holes through the board, looping the wire, up and back down to keep it secure and to provide tie points into heavier wire.

After the project is complete, mix clear five minute epoxy and apply to the fine wiring beneath the board. This makes the wiring practically immune to breakage, and is especially important if you intend to haul the sign around.

The cabinet may be constructed of any suitable material. I used plywood and 1 x 2 inch moulding for the framing, glued together.

One added thought: My particular sign contains an abbreviation, PCT. The period is formed with an NE2 and a 100k resistor wired in series between pin 13 of a nixie and segment string "C". Any small additional punctuation may be made in this manner.

Those of you who are in business will find many uses for a changing letter display. Others may end up with a novelty such as BAR OPEN / DOWN THE HATCH, or an alternating house number and street name, which would be a real conversation item.

So get out your scratch pad and start doodling. Who knows what you might come up with! ■

Liquid Crystal Display Guide

--for low, low, low power consumption

W. J. Prudhomme WB5DEP
1495 Richland Avenue
Metairie LA 70001

Digital displays are beginning to show up everywhere – from sophisticated electronic equipment to everyday items such as ranges, clocks, calculators, and wristwatches. There are presently two basic watches available: One has a liquid crystal display and the other an LED with a push-button switch to conserve battery power. In other words, with an LED digital wristwatch you still need two hands to tell time.

Actually, each new application of a digital display has resulted in continued improvements of display capabilities. For example, the present state of the art has evolved through incandescents, cold cathodes (neon, gas discharge or plasma), fluorescents, light emitting diodes (LED), and liquid crystal displays (both dynamic-scattering and the newer field effect types).

With new advances being made very day, perhaps it would be beneficial to review the many digital displays available and provide you with some information on how to apply them in your next project. My own experience has been that unless you have complete data on the particular device you are using, problems can arise through misapplication. Perhaps this article will serve to acquaint you with the characteristics of each device and serve as a handy reference. Emphasis will be on liquid crystal displays since I feel these devices will dominate the display field in the future.

Display Types

It would not be appropriate if we did not begin our tour with the NIXIE (a trademark of Burroughs). This device is one

Display Model	Height (inches)	Drive Voltage	Power Consumption	Remarks		Manufacturer	Available From
3601	0.6	15-20 V ac	2.25 mW	3½ digit instrument display		Hamlin, Inc.	KA Electronic Sales
3501	0.47	@	1.5 mW	8 digit calculator display		Lake & Grove St.	1220 Majesty Dr.
3401	1.12	15-120 Hz	3.75 mW	3½ digit clock display		Lake Mills, Wis.	Dallas, Texas
			(all segments energized)			53551	75247
7543 (R/T)	0.5	Transmissive:	0.5 uA	3½ digit instrument		Liquid XTAL	Various
		4-6 V ac @	per digit with			Display Inc.	Distributors

SSSI		7 V ac	0.5 uW	Field effect type		ILIXCO	Solid State Sales,
P/N:	0.4	@	per	3½ digit instrument			Inc., P.O. Box 617
84-06051		30 to 100 Hz	segment				Columbia, Md. 65201

Fig. 1. Typical liquid crystal displays available with general characteristics for each type. The low voltage types (7 V ac or less) are field effect types, while the 15 V ac models are usually dynamic-scattering types.

of the oldest electronic displays available and it has a different element for each numeral 0 to 9. An obvious disadvantage of this display is that each of the numerals is on a different plane, besides requiring a very high operating voltage. Despite the initial drawbacks, these displays have served us well and we continue to see them used in various pieces of gear.

The next phase in the development of displays evolved into the seven segment variety with which we are all so familiar. There are several different types, one of which uses incandescent lamps to light each segment. New methods have greatly increased the reliability of incandescent displays and we are seeing lifetimes of 100,000 hours as evidenced by the Chicago Miniature Lamp CM5. The main advantages to incandescents are brightness and the availability of full color with proper filters.

Gas discharge displays are seven segment devices which operate with a high anode voltage in the neighborhood of 100-180 volts, but feature low power consumption. An example of this display is the familiar Burroughs Panaplex. A high potential between the anode and the cathode characters causes the segment to glow, much the same as a neon tube. A resistor is usually connected in series with the display to limit the current to a safe value.

Fluorescent displays, on the other hand, incorporate a small filament in the display which effectively lowers the ionization potential. They feature lower voltage (20-30 volts), and low power consumption, and emit a blue-green color. The main disadvantage is the requirement of power for the filament, usually 1 or 2 volts @ 40-50 mA. However, the lower anode voltage makes the fluorescent display easier

Parameter	Dynamic - Scattering	Field Effect
Capacitance Above Threshold	5-35 pF (per segment)	5-35 pF (per segment)
Capacitance Below Threshold	2-15 pF	2-15 pF
Resistance Above Threshold	1-10+ megohms	400+ megohms
Resistance Below Threshold	500k-5 megohms	200+ megohms
Drive Voltage	12-20 V ac	2-8 V ac
Typical total Power Consumption (3½ digit watch)	50 uW	1.0 uW

Fig. 2. Typical characteristics for liquid crystal displays. Note the total power consumption at the bottom of the chart. By comparison, a 3½ digit LED watch display consumes 60 mW or 60,000 times as much power as the field effect LCD. The ac drive voltage may range from 25 Hz to 1 kHz although 32 Hz is typical for battery operated equipment and 60 Hz for line operated equipment.

to multiplex, which is the reason you may see them in desk-top calculators.

Now enters the light emitting diode (LED) on the scene and it becomes a whole new ball game. The LED is solid state and is usually made from gallium arsenide phosphide or gallium arsenide. Each of the seven segments usually consists of one or more LEDs whose brightness is dependent on the current applied (up to a point).

LEDs are susceptible to failure from overcurrent conditions and/or too high an inverse voltage. They are available in either 7 segment or dot matrices which can display alphanumerics. Usually red in color, yellow or green displays can be obtained at a slight premium. Until recently, they were available with character height from 0.1 to 0.8". However, one manufacturer has just announced a 1.0" LED which uses two diodes per segment, requiring a larger power consumption. The display from IEE, Inc., requires 3.3 volts @ 20 mA per segment and is 0.5" wide, giving it a slimmer appearance when compared to other LEDs. LITRONIX has also followed suit with the announcement of a new 1.0" LED display.

LED 7 segment displays are either common cathode (decoder/driver provides source current to the display), or common anode (decoder/driver sinks current from the display). Up until now, LEDs have dominated the display field, but as we will be seeing, a new generation of devices is about to emerge.

Liquid Crystal Displays

We are all aware that the liquid crystal display (although the effect was discovered many years ago) has taken a back seat to other, more popular, displays. This is not too surprising, since early LCDs had life

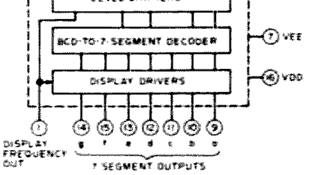

Fig. 3. Functional block diagram for the CD4055A BCD-to-7 segment decoder/driver with "display frequency" output.

expectancies of less than 5000 hours and would fail completely if operated below -20° C. The problems experienced when it was first introduced have hampered the LCD in gaining popularity. In spite of this, the LCD has some important advantages that are worth considering.

Of all available displays, LCDs are the only ones that do not generate light. Rather, they scatter any light striking the display's surface. The two basic types are reflective (requiring illumination in front) and transmissive (which requires light from the rear). Since these devices do not generate light, they have the lowest power consumption requirements of any display developed to date. For example, the RCA TA8046R 3½ digit watch display with all segments energized requires a total current of 1.0 uA @ 15 volts! The average device dissipation (with 70% of segments energized during a 12 hour period) is only 10.5 uW.

While another advantage is readability in highly ambient light conditions, the LCD has a disadvantage of low readability in dimly lit areas. This, however, is being overcome with back lighting which is turned on for a reading in the dark. This does not offset the LCD's low power consumption, since studies have shown that watches are read very seldom in the dark.

Also, power consumption is dropping to even lower levels. With the development of field effect LCDs, it's possible to have a 200 mil high, 3½ digit LCD display that draws a total of 200 nW. Life expectancy is also increasing, with some units up to 100,000 hours.

Applications

The predominant application of the liquid crystal display to date has

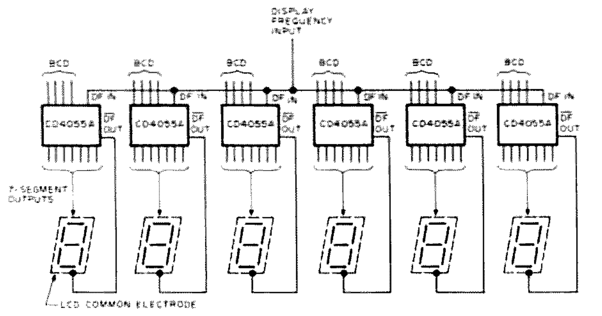

Fig. 4. Typical driver circuitry for liquid crystal clock display.

been in wristwatches, mainly due to their low power requirements. These displays are usually about 0.17" in height and a typical 3½ digit watch display can operate for a full year from a single dry cell watch-type battery.

You may be asking yourself, if the LCDs are so great, why haven't they appeared more in projects and articles? Perhaps the past reasons have been unfamiliarity of how to apply LCDs, price, or unavailability from the usual distributors. Notice I said "past reasons," because things are beginning to change fast and the LCDs are looking better every day (see Fig. 1).

Besides low power considerations, LCDs are ideal for use with CMOS circuits. It is now possible to construct compact portable equipment that can operate over extended periods of time from lightweight batteries. Also, for line-powered systems, the mating of LCDs and CMOS simplifies the driver circuitry, and eliminates current-limiting resistors.

Before you can properly apply LCDs, it will be necessary for you to put some of the LED techniques aside and consider a few new ones. To begin with, think of an LCD segment as a voltage dependent resistor in parallel with a capacitor instead of a diode as with the LED. The resistance of the segment is high above its threshold voltage and low below the threshold voltage. By now you may be realizing a primary difference between LCDs and LEDs: An LCD requires an *ac* voltage to operate and will actually be damaged by the application of dc. Consequently, driver circuitry is different, but in many cases less complicated than the LED driver. The basic parameters for both dynamic-scattering and field effect units are summarized in Fig. 2.

In addition, LCDs are temperature sensitive. Where an LCD is brought below or above its rated operating temperature range, it loses its liquid crystal characteristics. However, the condition is not permanent and the effects of temperature are reversible. When the LCD is brought back within its operating range, it will function again.

CMOS – LCD Decoder/Drivers

For a decoder/driver the Motorola MC14511 and MC14543 or RCA CD4055 and CD4056 can be used to drive the display (see Fig. 3). Also, there are many large scale integrated circuits available that provide parallel drive and eliminate external circuitry.

The RCA CD4055 and CD4056 are single digit BCD-to-7 segments that provide level shifting of the output. For example, output voltage swings of 0 to -3 volts or 0 to -15 volts are possible to drive either dynamic-scattering or field-effect displays. Fig. 4 shows a typical circuit for a clock display.

The CD4055A is a very versatile decoder/driver which can also be used for either common anode or cathode LEDs as well as LCDs. For example, if the DF input is maintained in a "low" state, the output segments will be "high" when selected by the BCD inputs. If the DF input is maintained in a "high" state, the output segments will "low." To drive an LCD, a square wave at 30 to 200 Hz is fed to the DF input. The selected segments will have a square wave output which is 180° out of phase with the DF input. When the DFout is level shifted (DFout) and applied to the LCD common line, the selected segments will be activated and displayed.

Where to Obtain LCDs

At present, I know of only three electronic suppliers catering to the ham market who advertise LCDs. Poly Paks has a small RCA wristwatch (3½ digit) display available, and KA Electronic Sales (Dallas) handles the Hamlin line of LCDs including a 3½ digit instrument (0.6" height), clock display (1.12" height) and an 8 digit (0.47" height) calculator display. Also of interest is the LCD sold by Solid State Systems, Inc., which is a field effect type from ILIXCO. This LCD is a 3½ digit (0.4" height) instrument type display and sells for $7.75 including the connector.

So let's get busy and start designing some equipment using liquid crystal displays. I think you will be pleasantly surprised with the results. ■

Self-Powered Mike Preamp

-- when you need to SPEAK UP

While operating different SSB transceivers, I've noticed the difference in transmit audio gain between the different rigs on the market. The obvious solution for making up the gain necessary was the addition of a microphone preamp to each rig. After researching the literature for mike preamps, I soon discovered that most preamp circuits were too complicated or required power from the rig itself. A solution seemed to be battery operation of the preamp so it could be operated independently and be used with all rigs without any modifications necessary. My favorite hand mike is a Turner model 350C, which uses a ceramic element. A mike preamp was designed to boost the low level from the ceramic element to a more respectable level. The preamp was small enough to permit installation into the mike case itself, including the battery.

The three design objectives were small size, low power consumption, and operation over a wide battery voltage. Fig. 1 shows the design used to permit the use of an extremely small circuit board size. All components, if mounted on end, will fit on a tiny 1.5cm x 1.5cm vectorboard. This small board will fit inside of the Turner case as well as the case of any hand mike. The preamp is a common source amplifier with a gain of +20 dB. The frequency response is flat from 200 Hz to over 100 kHz. Because of the single FET stage and small voltages amplified, the power consumption during use is less than 200 uA. When not in use the power consumption is zero, permitting long battery life. Since the small circuit board easily fits into the Turner case, the only problem left was the placement of a battery. I found an Eveready 15 volt battery ideally suited for powering the preamp. The preamp circuit was designed to work down to a battery voltage of 7 volts, so the battery could be used as long as possible. Since the current is drawn from the battery only during transmissions, the battery should last nearly as long as its shelf life. The preamp has been left in the on mode for over a month before preamp failure due to low battery voltage.

The Eveready battery chosen is designated by the number 411, and costs less than $1.75 in single quantities. Its dimensions of 3.2cm x 2.5cm x 1.6cm allow it to just fit inside of the Turner case, as shown in Fig. 2. The battery rests on top of the mike cord where it enters the case, causing a clearance problem. This problem was resolved by carefully melting down the plastic cable strain relief channel with a soldering iron. The mike cord can then be pushed slightly deeper into the case, providing more room for the battery.

The push-to-talk switch was wired to disrupt the preamp output when not in use. A small power diode capable of handling the push-to-talk relay circuits was added to disable the preamp when not being operated. A small signal diode was inserted in series with the battery to prevent the reverse biasing of it during receive.

Since this mike preamp is self-powered, it can be used with any rig lacking in transmit audio gain. Since 20 dB of gain is used, overdriving the transmitter might be possible. The transmitter's mike gain will probably have to be adjusted to a low value to prevent excessive drive. The self-contained battery should last over a year, even with daily use of the mike. Although modifications were done on a hand-held Turner mike, the same circuit will work with other ceramic or crystal hand-held mikes, as well as with desk mikes. The only consideration would be the battery size. ■

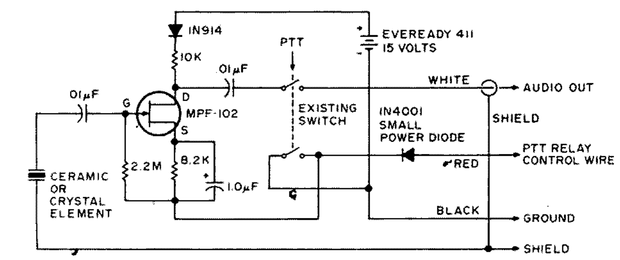

Fig. 1. Diagram of the preamp, which fits into the mike case. The unit requires less than 200 uA during use, and no current when not in use, permitting extended battery life. A small vectorboard is used to mount all components.

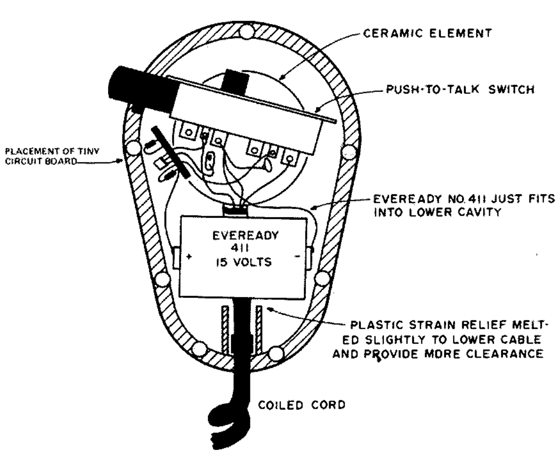

Fig. 2. Pictorial of the inside of the Turner case, which is similar to other types. The preamp circuit board and battery easily fit into the cavity. Battery terminals are soldered too, since a socket would not fit.

See the World and Get Paid!

-- merchant marine radio officers: part I

A radio officer is a licensed United States Merchant Marine officer. He is a civilian who holds a dual license: a (minimum) second class radiotelegraph Federal Communications Commission (FCC) license and a United States Coast Guard issued Merchant Marine officer's license.

The primary responsibility of the radio officer is to satisfy the requirements of the International Act (Geneva) For Safety At Sea, which requires certain class vessels to have licensed radio stations and to keep watch on the international calling and distress frequency of 500 kilohertz. Thus in any distress situation assistance may be readily supplied or requested. Secondarily, the radio officer, under the authority exercised by the master of the vessel, handles communications between the ship and the ship's owners. Communications in the form of marine cables received and sent via commercial maritime stations comprise the bulk of traffic. However, modern day merchant ships often carry sophisticated voice communications equipment — single sideband, VHF, medium wave radiotelephones, even state of the art satellite facilities. Some vessels have radioteletype terminals. Weather and hydrographical information is often acquired via fascimile circuits. All this varied "communication" is essential in today's merchant fleet and requires competent, knowledgeable people to fill the role of radio officers.

The purpose of this primer is to provide accurate, practical data to those wishing to investigate a career as a Merchant Marine radio officer. While one must leave home for varying periods of time, the type of work involved is interesting; the travel, often to exotic ports; the financial remuneration, excellent. There is a limited amount of published information available. However, the novice would be hard pressed to gather a goodly amount of pertinent data without much laborious research and its attendant difficulties. I am, and have been for ten years, a licensed radio officer sailing with a major oil company tanker fleet. I have had experience on various classes of cargo and oil tanker vessels. My travels have routed me to the main ports of the world. With this background, I am able to give precise information concerning present day conditions in merchant fleet communications, discuss types of equipment and their maintenance, relate first hand details on major maritime traffic stations worldwide, and offer positive guidance on license attainment and avenues of employment. While not everyone who wishes to can become a radio officer, those with a sincere interest, drive sufficient to acquire the necessary knowledge and certification, and persistence in seeking employment, can become involved in this secure, rewarding and worthwhile career.

Licensing

Anyone aspiring to the career of Merchant Marine radio officer must have the initiative necessary to obtain the minimum license requirements. These are twofold: First, an FCC second class radiotelegraph certificate must be acquired. Secondly, upon issuance of the FCC license, seaman documents may be applied for with the radio officer endorsement. A U.S. Coast Guard Merchant Marine officer license will also be issued running concurrently (five years) with the radiotelegraph certificate. The following will detail possible methods of obtaining this certification.

Many people interested in a seagoing career as "sparks" already have a general background and interest in electronics. More particularly, some are even licensed radio operators in other types of

FCC service. Radiotelephone permits and amateur radio and citizens band tickets are the more commonly held Federal Communications Commission licenses. If a person has an amateur radio license, then he is familiar with the type of testing procedure employed by the FCC engineers. Like the amateur examination, a commercial second class radiotelegraph license examination is divided into two parts: the Morse code portion (20 words per minute) and the written technical examination (sections of the examinations are referred to as "elements").

Exact regulations governing test requirements are found in FCC rules and regulations. These are grouped into ten volumes. Each volume is divided into sections. Any volume or group of volumes can be obtained from the U.S. Government Printing Office.

Specifically pertaining to commercial radio operators would be Volume 1, Part 13. Volume IV, parts 81 and 83, give complete FCC regulations concerning maritime services. Part 81 deals with land based maritime services (coastal station operation). Part 83 contains regulatory matter directly concerning shipboard stations in the maritime service. Every United States registered vessel with a licensed station onboard is required to have on file copies of sections 81 and 83. If one fully masters the rules contained in these two articles, the "regulations" element of the written examination will be easily passed.

Thus, to qualify for a second class FCC radiotelegraph license (minimum requirement for shipboard operators), one must first successfully pass the Morse code test and then achieve a passing grade on the written examination. Let's delve into each of these two items.

To copy and transmit Morse code properly is an acquired skill and art. There is no "easy" way other than to diligently apply oneself to the mastery of the code. While "shortcuts" and mechanical aids are available to help one learn the sounds and proper rhythm of Morse, it is through the basic learning processes of concentration, repetition, and involvement that any person becomes proficient in handling code. A popular method by which thousands have learned the Morse alphabet is to memorize a few letters at a time until the entire twenty-six letters can be repeated and written without hesitation. Some find grouping letters with similar Morse sounds helpful; others find

that opposite characters such as "A" and "N" prove helpful to their memories. Once a person has a good "sound" memory of the individual letters and numbers, and can recall them instantly, then work can begin seriously on acquiring speed. At this stage "cassettes" or tapes with code practice are an invaluable tool. If one is fortunate enough to possess a shortwave radio receiver, actual Morse signals can be used for practice. To recognize a letter every now and then in a plain language sequence will rapidly lead to faster, solid copy. Schedules of traffic lists and weather bulletins of leading commercial stations are found in Section Ten. Traffic lists are excellent practice, as the calls are repeated twice and are random letter and letter-number combinations. Station WSL, Amagansett Radio, New York, offers excellent weather schedules. This station is one of the fastest on the east coast. The schedules are sent on tape which approaches perfect CW sending. Once a person can copy, for example, the 2300 GMT weather schedule of this station, then the code examination for the FCC license is well within reach.

In learning any new skill, certain levels of achievement are reached and sustained. With Morse code these levels or plateaus can be bridged through increased effort and practice. The range of seven to ten words per minute for most is easily reached. Ten to fifteen wpm (words per minute is based on five characters to a word) requires sustained effort. The goal of twenty words per minute and beyond is achieved after persistent application to practice sessions. The FCC code test runs five minutes. An applicant must copy any one of the five minutes perfectly. Ordinarily this is not extraordinarily difficult. However, the "nervousness" factor is present as one takes the test under the watchful eye of the presiding FCC engineer.

A word here concerning actual code speeds used in shipboard/marine station traffic work. Once a person begins working commercial stations and puts in eight hours daily on a radio circuit (monitoring 500 kHz, weather reports, traffic lists, etc.), speed and accuracy steadily improve. With time, Morse ability becomes somewhat of a reflex action. I am often amused (perhaps forgetting my own real uneasiness once) at shipboard visitors inquiring about becoming radio officers. Most often their main concern is the ability to send and receive quickly. This skill gradually develops and becomes almost an automatic response. This allows one to then concentrate on other, more technical, aspects of shipboard communication, maintenance of the electronic gear being a major item.

As closing comments on the Morse code, it is generally accepted between commercial land marine stations and shipboard stations that "twenty is plenty." In other words, 20 wpm is quite sufficient to handle normal ship communications. However, many coastal stations are extremely busy with lots of traffic (messages) to send and receive. If the ship's operator is agreeable and capable, operating speeds will often go to 25 wpm and beyond. The point is, as long as solid copy is being achieved on both ends of a circuit, speed is adjusted accordingly. It is better to slow down and copy correctly the first time, rather than consume additional time getting "fills" (missed portions of messages – most stations use full "break-in," one operator can signal another of a missed word by the tap of the Morse key). Some ships will handle more traffic than others. Ships on coastal runs (east/west coast and Gulf of Mexico) will generally have occasion to send and receive more messages because of the frequency of ports. There are certain routine series of messages which concern the normal operation of the vessel: arrival times, crew changes, stores, cargo information, and other pertinent data.

With the code test successfully passed, the next hurdle is the written part of the examination. As a practical guide it can be stated that the written test covers three categories of knowledge: Federal Communications Commission rules and regulations concerning the maritime service, basic electronics theory, and basic communication equipment theory (receivers, transmitters, power supplies and related equipment).

There are several question and answer manuals available which cover all of the above categories. Often the answers to simulated test questions in these manuals will go into profuse detail for informational purposes. One recommended Q and A manual is Kaufman's particular edition. This is a comprehensive guide which covers all phases (elements) of various commercial license test requirements. There are other excellent study guides available found at most electronic supply outlets or specialized bookstores. Another text which has a wealth of background information is the *Rider Basic Electronics* series. This can be bought as a single large edition or five individual softbound volumes. It is well illustrated and technically but simply written. Sections on power supplies, transmitters, receivers, test devices, and even transistors are intended to give the reader a broad knowledge of basic electronic circuits and their behavior. Of course, any background a person has in electronics is obviously helpful. The *Radio Amateur's Handbook* is a practical and comprehensive reference work which covers a large segment of the radio frequency spectrum usage. It describes practical operating circuits for radio receiving and transmitting, plus additional chapters on specialized communications systems such as teletype, narrow band FM, satellite communicating techniques and others. Using these and similar aids, as well as a careful study of the FCC Rules, Volume IV, should adequately prepare one to succeed in the written examination. As added insurance to acquiring the license, commercial correspondence courses as well as residency classes are offered by various schools and institutes. Some of these carry a type of guarantee which allows a person to continue studies until successful acquisition of the desired license.

At this point one might well ask, "How much time will it take to prepare well enough to pass the test without waiting to repeat it?" This question is difficult to answer. Each person has different capabilities, memory, and grasp of abstract ideas. Some can memorize quickly and give back information without true understanding. Others can digest material and give back its essence showing complete grasp of the subject. Both approaches will successfully pass the examination; as long as one can correctly answer the multiple choice items (except for a diagram schematic or two), a passing grade will be achieved.

Some people devoting full time to studying for the examination – dividing the time between code practice and study of theory – could possibly be ready to "sit" for the examination in as little as eight weeks. Others, perhaps more methodical or thorough, may require two or three times that amount of

time. In my case, bringing a general background in electronics plus three years experience as an active ham used to CW procedures, the test was successfully passed after a solid month of long days of preparation (often 12-14 hours a day). It is always better to be overprepared to help overcome any nervousness factor. Each person will have to evaluate his or her own abilities in judging how much study is needed to feel comfortable going into the examination. Some attempt it after short preparation, fail it, then restudy and pass it thirty days later. They reason that the first sitting gave them a better idea of what to emphasize in their preparation. This procedure isn't recommended, but it is definitely one which has been used.

It is well to mention here that one's motivation is important in license examination preparation. Once a person has examined a potential career opportunity and set goals to attain membership in those ranks, then the necessary driving force will be there to get one over the difficult steps in attaining the goal. As outlined previously, a radio officer in today's modern Merchant Marine has considerable responsibility. The possibility of disaster, though not a morbid preoccupation, is an ever present reality – an event which places the lives of the crew on the radio officer's electronic expertise. Rigging emergency antennas, quickly repairing faulty or damaged radio gear – all these are paramount to getting out a distress call asking for assistance. Not secondary is the excellent financial remuneration the seagoing radio operator enjoys. A person employed full time for a private company fleet can realistically expect his earnings to be between twenty-two and twenty-five thousand dollars a year on American flag vessels. Union contract ships have equitable salary scales. Employment on some of the larger foreign flag vessels will pay salaries in the neighborhood of ten to twelve thousand dollars per year. In addition to the high wages paid, radio officers, like all Merchant Marine officers, enjoy outstanding benefit packages. These items will be mentioned in another section. Thus, should license preparation require even several years of part-time study to achieve success, the rewards are certainly handsome for those who persevere.

Once the second class radiotelegraph license is in hand, the radio officer aspirant can proceed to obtaining complementary United States Coast Guard documents. The first step toward accomplishing this after the license is acquired is to obtain a letter of commitment. This is a statement of intent, on company/union letterhead, that the bearer will be employed in the capacity for which license application is being made. This letter of commitment is a Coast Guard requirement. It is one method of managing the employment situation and controlling excess licenses being issued. Many companies and agencies involved in ship management may issue such letters of commitment. Also there are two national unions from which the commitment statement may be requested. With union and private union contracts expiring yearly, and new increased vacation benefits being negotiated, it is advantageous for unions to have certified men on file to fill the vacancies that evolve. Often one does not necessarily find final employment with the company or union which issued the original letter of commitment; however, once the letter of commitment is issued there is an obligation of it being eventually honored. One must seek out some marine personnel or union personnel manager who has potential job openings and is willing to take the time to issue the brief commitment statement.

The letter of commitment and the bona fide second class radiotelegraph license are the two major components necessary for acquiring the United States Coast Guard documents. Three other items will complete the file for issuance of the desired seaman's papers: proof of citizenship (birth certificate) and two passport size photographs. One may apply at any of the many United States Coast Guard offices. These are located in all major port cities. A physical examination is required and will be given at government expense. Abnormalities in health will constitute an impediment to obtaining documents. While shipboard life is not particularly rigorous, normal health is required due to often lengthy absences from usual medical assistance. Glasses (corrective lenses) constitute an impediment which is normally waivered. This process of actual application for Coast Guard documents may require one to two days depending on number of applicants to be processed. However, once completed, the actual certifying papers ("Z" card and Merchant Marine officer license) will usually be received in six to eight weeks.

While the licenses crown much effort and give a definite satisfaction of achievement, two major steps remain for becoming a full-fledged radio officer: initial employment and obtaining the six months sea service endorsement.

Employment Procedures

Federal Communications Commission regulations make it mandatory for a licensed radio officer to acquire six full months (180 days) of sea service on a United States flag (U.S. registered) vessel equipped with a licensed radio station before he or she is able to sail as a single operator. Since the majority of U.S. merchant ships carry only one operator, compliance with the six months endorsement requirement becomes essential for a future radio officer career. While a major deterrent to many licensed applicants in utilizing their hard earned documents, the FCC six months endorsement ruling evidences bureaucratic wisdom. A newly licensed radio officer simply must get six months' actual on-the-job-training experience before he is deemed truly qualified to assume the full duties of a radio officer on a single operator ship. Often the road to the six months endorsement is strewn with faded dreams, foundered hopes, and bitter disappointments. This section will endeavor to guide a newly licensed radio officer along this road so that the ultimate goal of full single operator status and security may be reached.

From the above discussion it is obvious that initial radio officer employment is closely linked with the necessity of achieving the six months sea service endorsement. A quandary is encountered: One cannot "sign on" as a single operator radio officer because the experience is lacking; the experience cannot be acquired because one is not allowed to sail single operator without the six months' sea service. What courses of action can alternatively be pursued?

A brief discussion is relative here concerning classes of vessels. Without going into confusing tonnage figures, let it suffice to say that international regulations require certain categories of ships

(generally merchant freighters, tankers, bulk carriers, passenger liners) be fitted with compulsory radio stations. Such equipment must be licensed, and a licensed radio operator must be a part of the vessel's complement. Other smaller types of sea craft (deep sea towing/tug boats, research vessels, fishing craft, large yachts) may be voluntarily equipped and manned. It is on this latter class of craft that new radio officer license holders can find employment leading to the six months sea endorsement.

In past years when the United States had many passenger ships registered, these were the normal avenues of employment leading to the six months endorsement. These vessels often carried three or more radio officers. A new license holder could apprentice on one of these ships as junior operator and acquire a wealth of experience in operating procedures, traffic handling and other job facets. Today there are no United States passenger liners. Some of the larger freighters carry the legal maximum of twelve passengers, which still allows the company to employ a single operator. The many cruise ships plying the oceans today are all registered in foreign countries. A person with United States documents may certainly apply for employment on these foreign flag vessels and often with success. However, the time accrued on such non-United States-registered ships does not count toward achieving the six months sea service endorsement. But the experience one can gain from such ships can be very valuable.

Other than seeking out the voluntarily equipped sea craft to acquire the needed 180 days' sea service, another alternative is available. A person may sail as a lesser unlicensed rating on a U.S. vessel — ordinary seaman, messman, utilityman, oiler — and with the company's and master's permission he or she may put in off watch hours in the radio shack in order to accrue the required experience. This scheme will probably take longer to acquire the endorsement; however, at the same time, pay is being received for one rating, few expenses are incurred aboard ship, and the opportunity of achieving the six months endorsement is available. Some companies or unions have programs whereby they will assign a newly licensed radio officer as second operator on a single operator vessel at reduced wages in order to allow the legal acquisition of the sea service sanction. This is usually done when openings are imminent. Fortunate is the person who applies to a company at such a propitious moment.

Summarizing, a person properly licensed for radio officer employment should vigorously pursue every avenue of opportunity. Persistent checking for union openings (both national and private company unions), applying to government agencies which employ civilian licensed personnel (MSC, Military Sealift Command, U.S. Coast and Geodetic Survey Agency), arranging interviews with owners of deep sea towing boats (often a combination of "deck hand"/radio operator position will be offered) and large yachts (information can be gleaned from brokerage houses for such craft): All these paths vigorously pursued will eventually yield positive employment commitments which will lead to the

necessary and coveted six months sea service endorsement.

It was my experience after applying at the above listed sources that a three to four month wait – a discouraging period with no word from the myriad applications filed – was unavoidable. When that time passed (time used to gain experience as a single operator on a foreign flag vessel), the offers began trickling through the mail. Eventually choices could be made.

While a formidable obstacle, the six months endorsement, once achieved, offers a reasonable degree of future job security. The numerical job possibilities increase a hundredfold. By this time many contacts will have been made (keep a notebook). Offers of "come see us when you have the endorsement" should have been filed for future reference. One will also be able to make a more mature judgment concerning whether to make a career in one of the national radio officer maritime unions or opt for private company fleets. Each choice has advantages and disadvantages. It is a question of committing oneself one way or the other. A young man or woman (25-35) fully qualified as a single operator radio officer has much to offer the shipping industry. Reciprocally, shipping companies are interested in stable, career-oriented personnel.

Salaries vary among various radio officer employers. As mentioned before, a person who sails full time as a single operator on an American flag vessel can anticipate earnings beyond the twenty thousand dollar level. Benefit packages also vary, but in general are excellent and comprehensive. Hospitalization, annuity plans, pension plans, life insurance, equity funds, and stock options are some of the types of total packages offered. Vacation time (paid leave is the colloquial expression) averages ten to eighteen days for each thirty days of shipboard employment. Efficiency dictates companies to allow this time to accrue. For example, several tanker companies will work their officers eighty to ninety days, then grant forty to fifty day paid leaves. Items such as base salaries, overtime rates, vacation periods, and other working conditions are negotiated frequently and upgraded to keep pace with industrial trends.

Thus, to a person contemplating a seagoing career, the rating of radio officer offers a unique opportunity: above average wages, worldwide travel, participation in outstanding benefit plans, retirement at a relatively early age with potentially large savings and an adequate pension. It is these incentives which should urge one to pass the discouraging phases of becoming completely qualified as a radio officer.

Reporting Aboard Ship

This section is a "tour" for the uninitiated of modern shipboard organization and routine. Particularly, it will outline a normal procedure for a radio officer to follow when reporting aboard a vessel. Most people seeking shipboard employment will probably have visited various types of oceangoing ships. (This is an excellent idea. Ask for the radio officer – most will be helpful in giving a ship's tour and a detailed explanation of the electronic equipment on board.) Thus a general familiarity with the physical layout of ships will be acquired.

A merchant vessel like any business organization is structured along certain lines. The following is a brief explanation of shipboard organization. The personnel on a vessel are divided into two broad categories: licensed officers and unlicensed crew members. Operationally, these people are then working in one of three departments. Deck department is responsible for the safety and navigation of the vessel, the maintenance of deck spaces, and the supervision of cargo operations. Engine department is responsible for the operation/maintenance of the power plant (steam or diesel), systems upkeep, maintenance of cargo handling equipment (winches, pumps, etc.), and overall responsibility for the mechanical aspects of vessel operation. Steward's department does the housekeeping of the vessel: preparation and serving of meals, cleaning of quarters, care of linen and other housekeeping chores. The departments and their specific members are listed below. Actual number of crew varies from ship to ship. Officers are considered supervisors. Other crew members have Coast Guard papers with specific job or rating endorsements.

Deck (Captain overall in charge)
Chief Mate
Second Mate
Third Mates
Radio Officer
Ablebodied Seamen
Ordinary Seamen
Bosun

Engine
Chief Engineer
1st Engineer
2nd Engineer
3rd Engineers
Oilers
Wipers
Pumpmen

Steward
Steward
Chief Cook
2nd Cook
Messmen
Utilitymen
Gallyman

Ship's routine is conducted in periods of time called "watches." Normally a crew member or officer will stand four hours on watch and be off watch for eight hours – thus midnight to four am, four am to eight am, eight am to noon and then repeat the sequence. This system works well and contributes to the safe conduct of the vessel. Some ships will "break" sea watches in port allowing doubling up for more time off in port. Others will maintain the four on, eight off routine without change.

The radio officer by law must stand one-third of sea time at watch. It is a safety watch consisting of monitoring 500 kilohertz, the international calling and distress frequency. All ship's communications are conducted during watch hours whenever possible. While leeway is encountered as to actual hours of radio watch, custom dictates the usual hours of 9 am to noon, three pm to five pm, six pm to nine pm. These hours allow for the copying of appropriate traffic lists, weather schedules and other communications matters. While at sea, when the radio officer is not on watch, an automatic device called an auto-alarm stands guard on the distress frequency sounding an audible alert should a distress situation develop.

A new officer reporting aboard a vessel will usually proceed directly to the radio room ("shack") to meet the person to be relieved. If the captain is available, introductions will be made. Should the ship be on a coastal run, the radio officer will be signed on by the master of the vessel and officially become part of the ship's muster. Signing on for foreign voyages is done before a shipping commissioner who comes to the ship for this purpose. License data is always incorporated into the ship's articles.

New radio officers will find that the person they are

relieving will be happy to spend time showing them the "ropes." Inspection, discussion of, and actual demonstration of the various electronic equipment will be part of the orientation. If the vessel is on a regularly scheduled itinerary, schedules, company procedures, and particular communications problems will all come under discussion. Reports, forms, log keeping, and maintenance procedures also constitute the relieving radio officer's briefing. As a new radio officer, don't hesitate to ask any and all questions. Once the radio officer you are relieving departs, the responsibility rests upon your competency. As a documented, qualified Merchant Marine radio officer, you will be expected to handle communication duties in a professional competent manner.

While bewildering the first time, one will find that experience allows this relieving procedure to become an informal, quick routine. The radio officer going off the vessel will usually leave a few typed paragraphs with key information. Usually, expected spare parts requisition forms, upcoming maintenance, or ordered shore-side repairs will comprise the file to be turned over to the relief. As physical layouts differ, a spare parts diagram location is usually found among the pertinent papers.

After official installation in the new capacity, the fledgling radio officer will usually have several days (except on tankers) while the vessel works cargo before sailing. This time can profitably be spent thoroughly informing oneself concerning the physical aspects of the electronic equipment. Radio office files will yield individual instruction manuals for each piece of gear. A careful reading of the manual with the radio equipment in front of you will help complete familiarization with the station.

While not going into specific details about various types of radio room equipment, for informational purposes most American flag vessels will be fitted with either ITT Mackay Marine or RCA Radiomarine installations. Sometimes there is a combination of both types of gear on one ship. Individual units such as transmitters, receivers, auto-alarms, auto-alarm keyers, battery chargers and so forth will often be consoled for convenience. This method provides a neat, efficient operating position. Many different manufacturers provide radiotelephone equipment. Collins Radio, RF Communications, CAI, Motorola, ITT, and RCA are but a few of many suppliers of single sideband, FM, and AM radiotelephone devices.

Radio rooms on foreign flag vessels are well equipped with systems provided by their respective countries. Two examples would be Marconi marine equipment found on many United Kingdom vessels and Electronik or Dansberg installations found on ships flying flags of the Scandanavian countries. Numerous other quality radio equipment manufacturers produce gear for vessels not flying the United States ensign.

Besides maintaining a listening watch on the distress frequency, the radio officer will generally copy weather bulletins twice a day. Each bulletin forecasts twelve hour weather system movement. If the vessel is equipped with facsimile receivers, one map is usually made daily unless some disturbed weather is being closely monitored. Other duties of the radio officer are to listen to applicable commercial station traffic lists for messages, perform required FCC tests, keep a current log, and generally keep the station in good operating order. ■

The Wind Counter

--the digital wind sock

Dave Brown·W9CGI
RR 5 Box 39
Noblesville IN 46060

Well, having voraciously consumed my recently arrived *73 Magazine* for March 1976, I concluded as always that therein contained is a wealth of information. Lest you think I conceitedly refer to my own two articles — I don't — I am referring to the great information contained in the article "Inherit the Wind" by W2AOO on page 72.

For several years I have been looking for a "weather station" device for this QTH, since I am out on a farm and rather unprotected from the wind — as a photo of our EME array in an earlier *73 Magazine* will testify!

The intent of this article is to add to Warren's fine article a couple of ideas that came up while rapidly brewing up his device for use here. Some of the ideas are purely mechanical ways of doing his ideas using the available parts that were either around in my "junque" box, or easily obtained due to past experience building one project or another.

Warren's idea using the L'eggs pantyhose containers is *great!* I have saved the darn things for years now, merely because there *had* to be a good ham use for such an item. It's like the plastic facial tissue containers that came out awhile back — they became good oval speaker holders in my test bench! Jello molds with a perforated cover make great smoke traps for smoke alarms, etc. Leave it to a ham to find a better use for the XYL's something or other. Along the same lines, a great material exists for outdoor enclosing of devices (loading coils, relays, etc.), and gets put into service here to house the wind pickup "container" mounted up my tower. That material is the PCV irrigation tubing available at supply houses, hardware stores, and most lumber yards. I used it to waterproof the buried cables going out to the EME tower house, and had a few short pieces left over. The tubing or pipe is approximately 4.250" in outside diameter, has .125" walls, and is quite rigid. It cuts readily with a fine hacksaw blade to the length you want. Nearly all the same sources carry accessory items for the pipe, such as the "Y", "T", and reducers, but not all carry the end cap. They do exist, and looking for two of them is well worth the effort, as it makes a very weather-tight enclosure when you slip these end caps over the pipe you have cut to length.

While at the store, look over an item called "chipboard," "particle-board," or "underlayment," depending on where you live. It comes in 1/2" or 5/8" thickness and in 4' x 8' sheets, though often smaller 4' x 4' or 2' x 4' pieces are sold for the weekend carpenter. This material cuts easily with a saber saw or even a hand jigsaw, and can be cut in circles to go into the PCV pipe to mount the top and bottom bearings. It can even be cut out and drilled for a platform for the LED and phototransistor pickup.

If you have read the

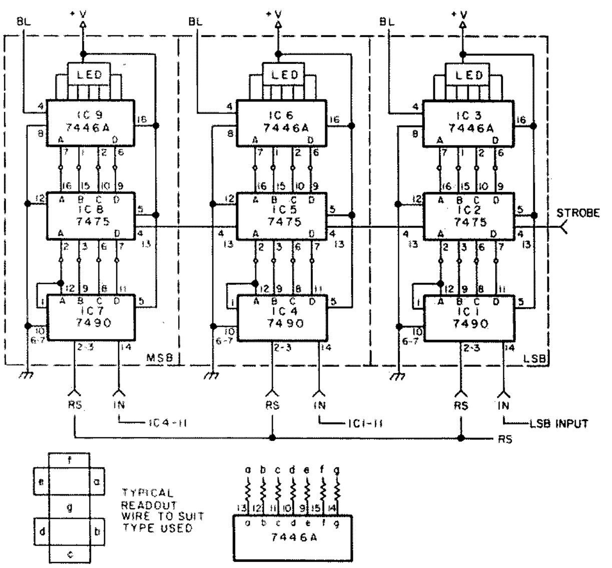

Fig. 1. Counter and readout. 7490 pins 8, 9, 11, 12 and 7475 pins 9, 10, 15, 16 should be brought to module plug; therefore a module socket of 14 lines is a minimum requirement.

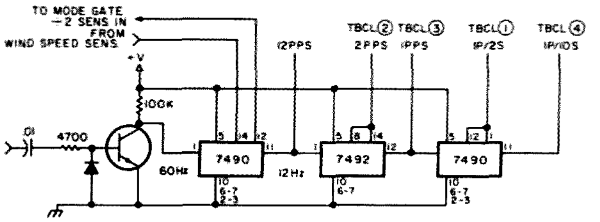

Fig. 2. "Cheapy" timebase.

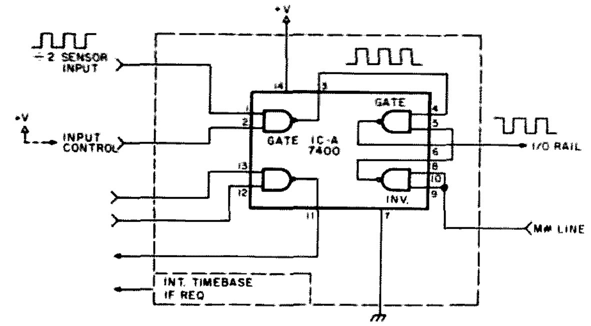

Fig. 3. Mode gate.

W2AOO article, you will readily see you are not going to get the 7" disc into my 4" I.D. pipe! Not to fear. There are easy ways around this.

I had held off building such a wind device for a long time since I was unaware how I would calibrate it. Also, I did not want to tie up a counter all the time, but for those of you without a counter, I fully agree with Warren – now is the time to build one! The K2OAW counter I built from three 1973 *73 Magazine* articles is a great starting point, and there are many updates. I am working on an article now on a 100 MHz basic and 650 MHz with scaler version. It uses the basic board from the K2OAW counter, since I already have built that one. With the TTL prices what they are, you are no longer talking about a 300-500 dollar instrument (i.e., to go from our 100 MHz to the 650 MHz is now about $19.95 – right out of a *73* ad – more on that another time).

The "counter" I am going to describe here is a special purpose unit, and as such can be built for even less than a home brew station test bench counter for your shack. It keeps the price to a minimum by doing such things as using the 60 Hz line frequency as a reference, but can be easily changed to a crystal timebase if you so demand. It has a "record" feature that you can build in, leave out, or add on later. It has a multi-mode deck for using it with more than one use that again can be left off, or added later. The very basic unit is therefore shown first for the wind speed indication only. The three digit capability is required for some of the later uses. Fig. 1 shows the basic display board and is built as a mother board with plug-in modules so things may be easily modified or added onto.

The basic counter and readout portion has been covered many times and should not need a detailed explanation. A stream of pulses comes from the pickup unit (wind speed in this case) through a control gate to the first counter. Each counter is a decade; thus the readouts read in ones, tens, and hundreds for the least significant to most significant bits or numbers from right to left.

LED readouts are so inexpensive now it doesn't pay to use anything else – see *73 Magazine* advertisements. The same source goes for the TTL IC logic required. If you don't mind the logic blinking during the count or are willing to add on the 7475 latches of my circuit, a good PC board can be readily had by building up the WA7SCB "counter" in a *73 Magazine* article from January or February this year. Since no high speeds are used, much lower power consuming MOS logic can be used for some of the circuits. I know of MOS equivalents for at least the 7400 and 7490 and they are the 74C00 and 74C90. They are pin for pin – just remove a 7400, plug in a 74C00, etc.

Fig. 2 covers the cheap 60 Hz timebase used in our inexpensive counter. A small portion of the 60 Hz is capacitively coupled out of the power supply to a discrete squaring circuit or can be fed to a 7413 Schmitt trigger IC. Hereafter, the output from this module is called the TBCL, or timebase clock.

The squared 60 Hz output from the 7413 or discrete squarer is fed to the ÷ 5 input of a 7490. Its output at 12 Hz is fed to a 7492 wired as a ÷ 6, then ÷ 2, for a 1 pps square wave output. The ÷ 2 function of the 7490 will be covered later. Of course for better accuracy, any one of a number of timebases leading to the same output (counter crystal controlled timebases, etc.) can be used into the same inputs that call for TBCL pulses.

Next, if more than one input is to be counted as I have plans to do (wind direction, etc.), some form of mode input gating must be used. Fig. 3 shows a simple gate arrangement using only one IC. Provisions for placing a secondary timebase on this module for future use are also shown. More on that later.

The incoming pulses from the generator-sensing device enter the mode gate at ICA-1, one side of a 2-input NAND gate. The other input, ICA-2, is used differently with different modes. The dotted lines show the hookup for the wind speed only version. ICA-3 is the output of this NAND gate and it goes to the input of a second NAND gate, ICA-4. This NAND gate allows the pulses to pass on to a common I/O line or "rail" for all modules only when the other input, ICA-5, is high. This occurs when ICA-8 is high, which is when ICA-9 and ICA-10 are low. They are tied together and

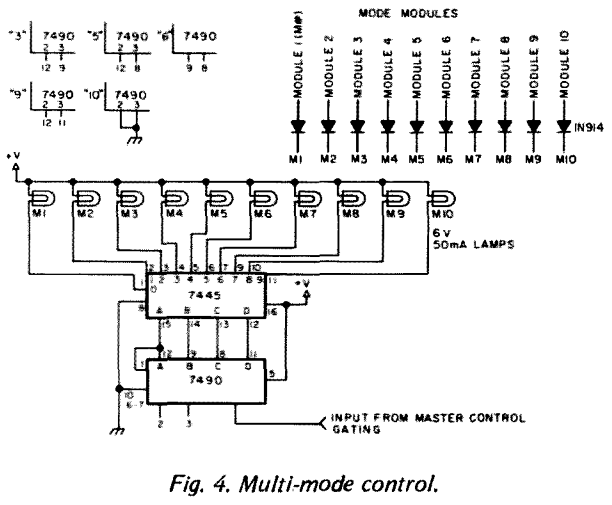

Fig. 4. Multi-mode control.

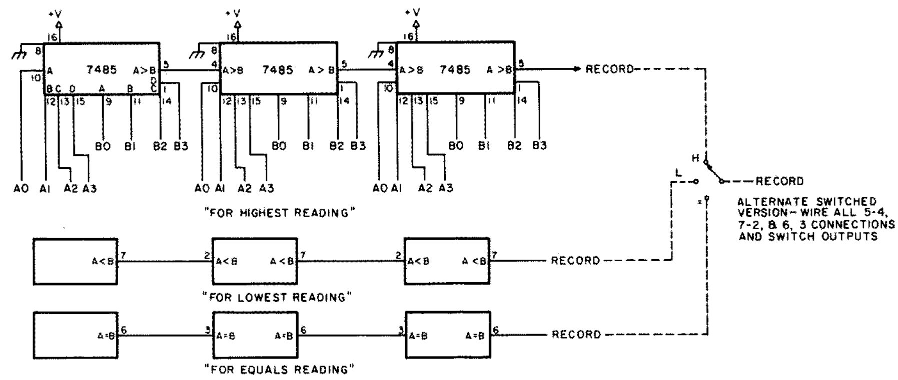

Fig. 5. Recording module. Pin connections: (A) A0 to IC7-12, A1 to IC7-9, A2 to IC7-8, A3 to IC7-11, B0 to IC8-16, B1 to IC8-15, B2 to IC8-10, B3 to IC8-9. (B) A0 to IC4-12, A1 to IC4-9, A2 to IC4-8, A3 to IC4-11, B0 to IC5-16, B1 to IC5-15, B2 to IC5-10, B3 to IC5-9. (C) A0 to IC1-12, A1 to IC1-9, A2 to IC1-8, A3 to IC1-11, B0 to IC2-16, B1 to IC2-15, B2 to IC2-10, B3 to IC2-9.

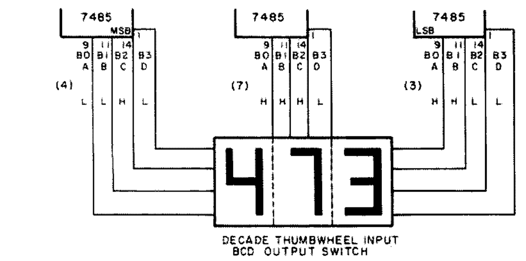

Fig. 5a. Wiring changes for fixed preset figure for B data.

this NAND gate is wired as a simple inverter. Again, the dotted lines show the wind speed only version. The M# line entering at ICA-9 and 10 is covered in the next module.

More than one mode may be monitored by adding the Fig. 4 multi-mode module. Modes may be added on easiest by certain numbers (3-5-6-7-9-10), and these combinations are shown. The module is an encoder (7490) run from the timebase and driving a 1 of 10 decoder (7445). The decoder outputs must be committed externally to +V in this decoder, and the easiest way to do this is to run each output to +V via a 6 V, 50 mA lamp. These lamps then also indicate what mode you are in. The diode is added to each line going to a mode module as added protection. As the timebase drives the encoder, the decoder steps from mode to mode, enabling the input modules as it goes.

An added feature I wanted around my QTH was an easy way to "record" the high or low readings for the day, and while reading through the first writing of this article and the W2AOO article, I realized how similar this requirement is to that of our EME automatic beam steering; therefore that type of device is presented here. Since most or all will want it, I did make it slightly more complex than a basic version would be, but it may be built in part for high only, etc., very easily. Just delete the functions you don't want. An example of use is the best demonstration of usefulness I can think of and reads as follows. First, the record feature can be used in a single mode device only, or where the 7475-7446 readout portion of the instrument is duplicated. It is seldom required to "record" more than one mode reading, so the version shown is for a single mode instrument. You may choose to record the highest readout (A > B), as in the highest wind speed, or only winds above a preset (by you) readout, in which case the readout is stored and the fact it was exceeded used to activate an external device (i.e., a crankup motorized tower lowered in high winds or an alert tone device triggered during tornado season to awaken the family). Or, you might choose to record and/or use the lowest reading (A < B). We are working on other sensors such as temperature, humidity, etc., and you may want to record the lowest temperature of the day (got your antifreeze in yet?) or temperatures below a preset reading – such as 32 degrees F (got the heater strip on the water pipe and the cat in for the night?). Or by adding a later clock module of sorts, you can turn on the house lights at dusk, etc. (A=B). It really can be made very versatile by building up and adding on our modules of future articles. Maybe you can think of something you want to monitor? Drop me a line and we'll see if we can write it up.

For you computer guys, we are already working on a little module to take the readout's information to the outside world as parallel or serial data and on to a teletype (hard copy of weather during a CD storm alert?), or to your computer to do goodness knows what. Using the computer at work is as close as I have gotten to that part of our changing hobby so far, but it does get my interest.

I'm sorry there are no board layouts at this time. We are very busy working on sensors, including wind speed, wind direction (leave extra room in the outdoor PCV pipe unit!), temperature (indoor/outdoor), humidity, barometric pressure, and such

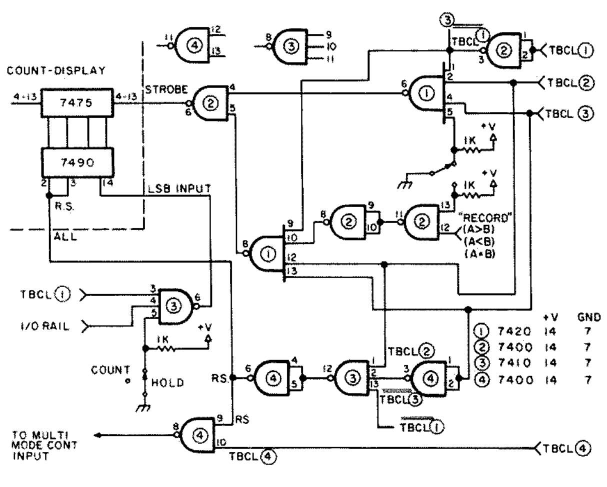

Fig. 6. Control gating module.

others as smoke, fire, and burglar alarms. The burglar sensor is such that shorting around it or shorting it to ground instantly sets it off! The sensors for the most part will be single IC devices. They generate a square wave that is modified by the item being sensed.

As for getting the wind speed running, cut your pipe and chipboard and arrange all the items just as in the original article. Your disc, however, should be cut to 3.75" to 3.80" in diameter to clear the inside of the PCV pipe. This means you have a radius of 1.90". Use a compass and scribe a circle of this radius on the 1/16" thick metal material as in the original. Scribe a line through the center and crossing both sides (straight line through the middle and crossing the scribed circle). Measure from the center along the line one way to a point 1.40" (1.400563499" for extremists) from the center. Center punch this point and the center. Drill the hole at the center 1/4" in diameter, and at the 1.40" point 1/8" in diameter. Now you can mount and assemble as the original, aligning the LED above and the phototransistor below the 1/8" hole. As the disc rotates, the hole produces a pulse every revolution. On a 1.40" radius, or 2.80" diameter, the circumference covered per revolution (or pulse) is 8.796". Every two revolutions (two pulses) the hole on the 2.80" diameter circle covers 17.59"; thus there are 2 pulses produced per second for a 1 mph wind. The sensor signal is routed through the mode gate, through the leftover ÷ 2 function of the 7490 in the timebase, and on to the control gate, as a 1 pulse per 1 mph, just as the original.

The control gating may vary or change as new sensors are developed, so it, too, was built as a module.

It should be easy to follow the gating in the control section. Just use the rule that the inputs to a NAND gate must all be high for the input to be low, and conversely, if any input is allowed to go low, a desired output high can be gotten.

I hope by breaking this up into module construction, each of you might find your own uses, be able to build your own versions, or be able to learn a little about TTL logic and use the circuitry toward your own designs. More input sensors and modules will follow as we perfect them, and I hope we then have more time so that board layouts may be provided for those who prefer PC board construction. I know how you feel, because I certainly prefer it. It makes it very hard to make any mistakes in wiring – hi.

At the cost of today's Pony Express, a SASE is sure appreciated for letters requiring a reply. I have gotten them on letters making only comments or suggestions for future articles, and while the loose stamps were appreciated (I do mail letters and I happen to collect stamps as another hobby – hi), they aren't required for that type of mail. Thanks anyway! On those types of letters, if they can be fit on a post card, by all means save yourself some money, and the comments and suggestions *are* really appreciated. On future board availability, etc., I will try to keep all advised via the *73* letters column if that is o.k. by you and Wayne (*sure . . . Wayne*). We have drawn up several "general" TTL type circuit boards that may be of interest to all, and I'll try to put them all together for a shorty article of nothing but that if there is an interest. They are very handy to "breadboard" up more complex circuits. You end up with multi boards, but maybe that isn't so bad. I hope this article helps make amateur weather observers of you. You would be surprised the effects it has on our radio hobby, and how appreciated the data is to your local CD net and weather bureau during the rough storms, tornadoes, etc. We sure have been warmly received by the local weather bureau during such times. Until the next modules, 73. ■

The S38 Is Not Dead!

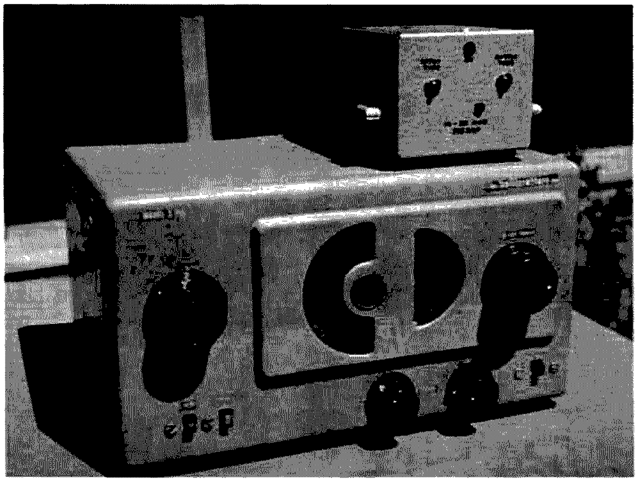
-- a tale of resurrection

I recently attended several San Francisco Bay Area ham auctions, with attached flea markets. For no particular reason, I ended up with an old Hallicrafters S38C, in the most bedraggled shape imaginable. The very condition of the old receiver was a challenge, and the steps in its resurrection to a useful receiver will be recounted herein. The hope is that these easy steps will inspire other owners of this all-time popular short-wave receiver to restore them. After all, there is still a large group of young experimenters, SWLs, and would-be Novices out there saving their quarters and dimes to get their hands on anything that will function as an HF receiver. To meet this group, simply attend the next ham auction or swapfest; it will restore your faith in the younger generation.

My receiver, as acquired, had no knobs, a torn speaker cone, a rusty cabinet, a missing receive-standby switch, no dial pointers, and (of course) was inoperative. Should yours be in similar shape, your first move should be to get a copy of the circuit (Sams' set 190, folder 4), preferably from a friend who does service work. Secondly, the speaker should be replaced; horizontal mounting of speakers in the tube-type sets eventually ruins them, so you might as well do it right away. Next pull the chassis, check tubes, and replace as needed. Be sure to replace the #47 pilot lamp if it's open, because otherwise you'll be buying a new 35Z5 rectifier tube shortly. A type #755 pilot lamp, with extended-life, might be considered here. The entire complement of eight or nine tubular (drippy, paper-wax type) capacitors should be replaced with the newer mylar and ceramic disc varieties. This step avoids the step-by-step isolation of a faulty capacitor, and should save time in the long run. I replaced the three-section electrolytic capacitor on general principles.

In the cosmetic area, I made new dial pointers by soldering short pieces of 1/16" brazing rod to grid-cap clips (1/4") and painted them white. The cabinet was wire-wheel cleaned of rust, masked, and painted with a spray-can coat of grey enamel. A new bottom plate was also made of sheet aluminum, and rubber feet attached. A set of four knobs (not original Hallicrafters, but adequate) was installed, and a new slide switch was put in the "receive-standby" position.

With these efforts, my receiver gave some indications of life, at least on the BC band. A simple i-f and rf alignment, following the procedure in Sams' with a signal generator, greatly improved sensitivity. At this point, the S38C was judged to be "as-good-as-new"; that



Hallicrafters S38C after resurrection, with FET preamp atop.

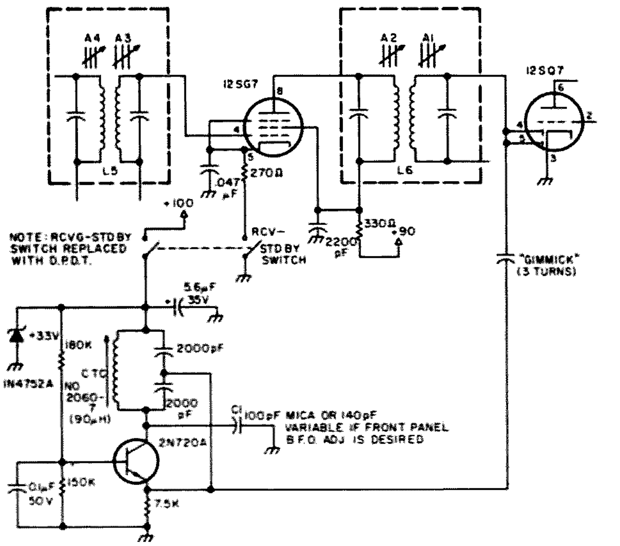


Fig. 1. New BFO in S38C. C1 = 100 pF mica or 140 pF variable if front panel BFO adjustment is desired.

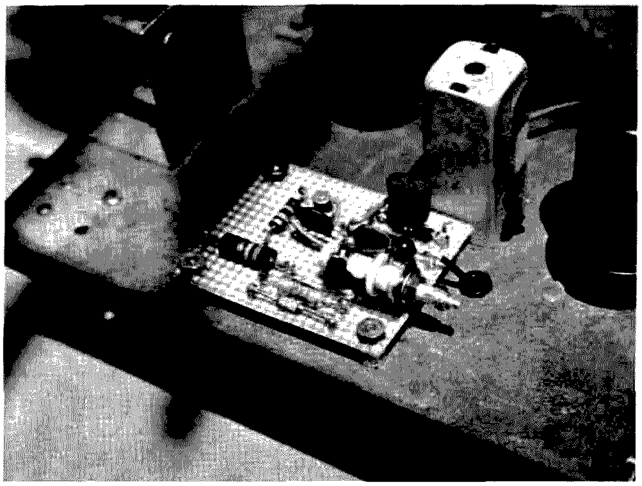
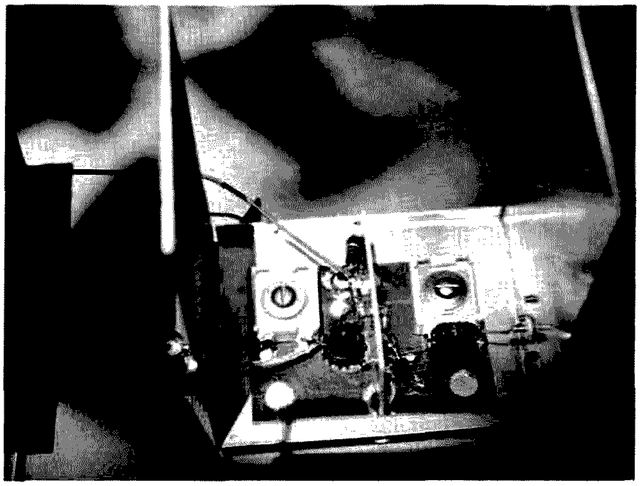


Transistor BFO mounted on S38C chassis.



Rf portion (except power supply) of 14-30 MHz preamp, mounted on section of copper PC laminate.

is, a *fair* receiver considering its design limitations.

Changes and Additions

The BFO function in the original S38C is fulfilled by causing the i-f amplifier to go into regeneration. This rather critical circuitry was eliminated, and a more conventional BFO added. Since the S38C is an ac-dc type of radio, it was easier to make the new BFO a transistor type and avoid heater voltage problems. The new BFO and its placement in the S38C circuitry are shown in Fig. 1. A few milliamps from the B+ are used with a zener to provide the +33 volts to operate the BFO. If a front panel BFO control is desired, C1 can be made a variable (140 pF) rather than a fixed capacitor.

The shortcomings of the S38C are several: lack of image rejection, inadequate selectivity, and inadequate sensitivity (for starters). The sensitivity can be increased and image rejection improved by the addition of a preselector. There are many adequate designs for such preselectors, but most of these date back to the same era as the S38C and similar receivers.[1,2,3] The photo shows a simple preselector using an FET. This is an add-on unit, not designed to be included in or powered by the S38C.

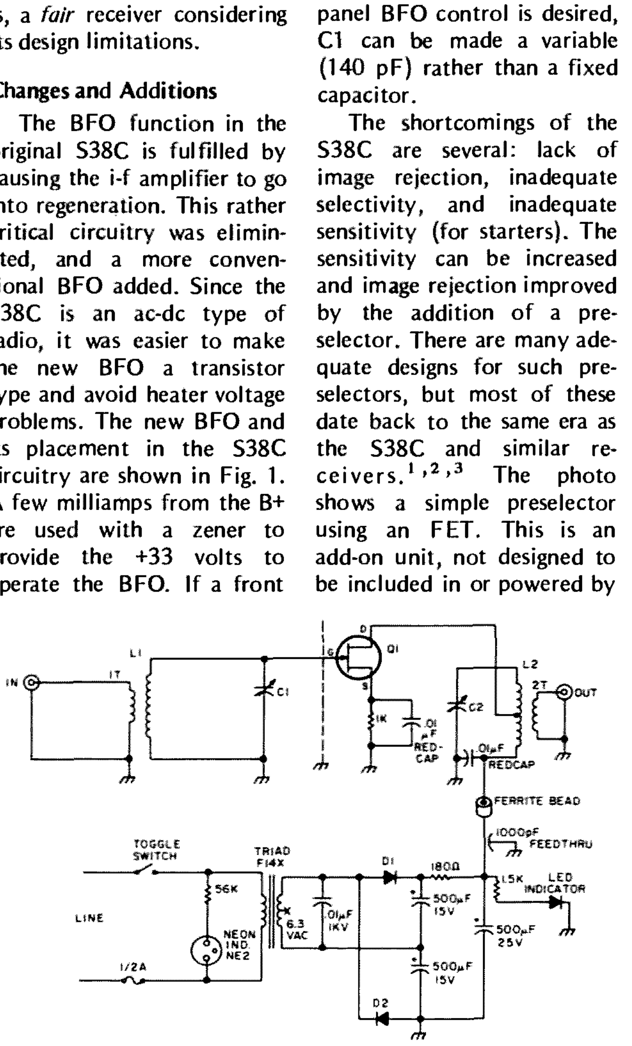


Fig. 2. Self-powered 14-30 MHz preselector for S38C. C1 = C2 = 50-500 pF (Miller 160B); L1 = 10T #22, T50-10 Micrometals core (0.37 uh) with 1 turn link; L2 = 10T #22 with c.t. and 2 turn link on T50-10 Micrometals core; Q1 = MPF102, HEP-802, HEP-F0015 (all Motorola); D1, D2 = 1N4002, HEP-R0051 (Motorola). Ferrite beads and Micrometals cores available from Amidon, 12033 Otsego St., N. Hollywood CA.

The preselector improves the overall receiver noise figure, and thus its sensitivity in the 14 to 30 MHz portion of the HF band. There is less to be gained by extending its range by adding the complication of coil switching for lower frequencies, since these frequencies are usually sky-noise limited. The preselector will help not only sensitivity but can also help reduce cross-modulation from strong out-of-band shortwave broadcast stations. The value in reducing images is noticeable too since the image is always 2 x 455 kHz away from the desired frequency. That is, at 14 MHz the ratio of desired frequency to image offset is 15/1. The coils used in the preselector have unloaded Q values of 100 or greater, and so would be expected to be of some help in image reduction. The Qs of the tiny powdered iron core coils used are nearly as high as one would obtain with air core type coils, and have a totally self-contained magnetic field. This latter fact makes it possible to use them in a compact preselector design with a minimum of shielding, yet one still having good selectivity and stability. The sensitivity improvement on 14, 21, and 28 MHz was measured to be between 10 and 20 dB; this is a significant improvement over the original. The basic preselector's circuit is shown in Fig. 2. The power supply section is not shown, as its layout is non-critical. The supply and preamp board were later combined in an LMB-140 box chassis, to package the unit for convenient operation. Note that two compression mica variable capacitors were used to tune the preamp; this was due to the scarcity of air-spaced tuning capacitors nowadays. Since *these* capacitors are screwdriver-adjust types, some may wish to substitute air spaced types – or modify the compression screws for shafts. If one band, say 15 meters, is used primarily, only slight retuning is necessary across the band, and a screwdriver adjust system is okay. The two 0.1 uF bypass capacitors in the preamp should be low inductance ceramic types (Erie Redcap are specified) to insure low rf impedances to ground at these points. Aerovox, Vitramon, and others make similar types of capacitors, however. ■

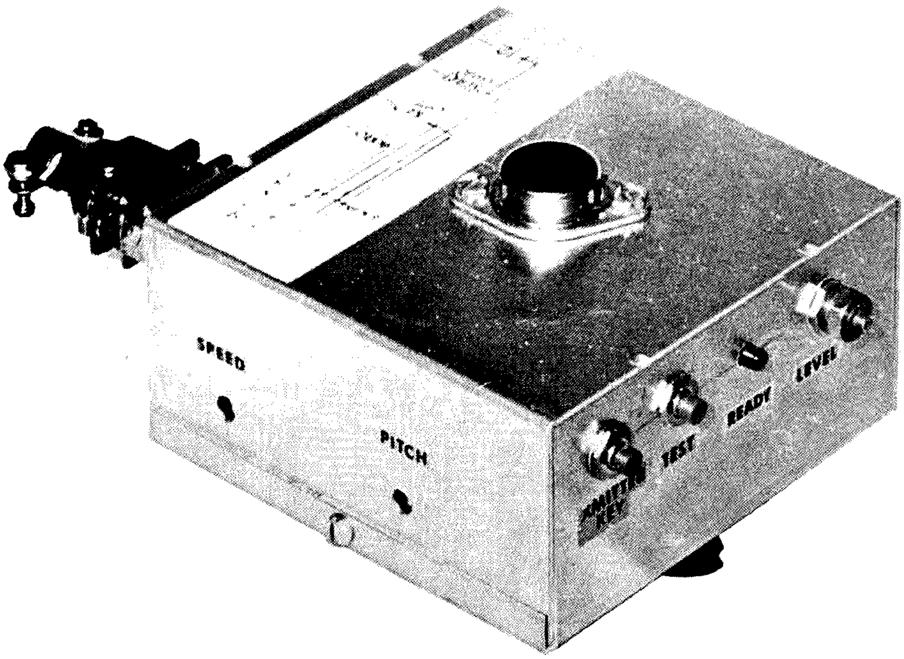
ID with a PROM

- - and program it yourself

William Hosking W7JSW
8626 E. Clarendon
Scottsdale AZ 85257

Here is another CW identifier using a Programmable Read Only Memory. Several circuits using PROMs have been floating around, but most of them were lacking one or more of the features I wanted. For my applications, I wanted a timed hold-off which would keep the IDer from being re-keyed within a specified time period. I also wanted the IDer to re-identify at the end of the time-out period.

This version of the identifier is about third generation, and conquers, I hope, some earlier limitations.



External view of the prototype identifier. The transistor on top is a five volt regulator. The XMITTER KEY button will key the PTT line. The TEST button sends the ID without triggering the timers. The READY is an LED (not shown on the schematic) which is on when the IDer is ready to be keyed. LEVEL sets the output level to the transmitter. PITCH and SPEED are self-explanatory and are screwdriver adjustments. The plug on the back was an afterthought in this case, for interface with our repeaters. The case is a 4" x 4" x 2" minibox.

Circuit

The basic CW generation technique is not new, and consists of U1, 2, 3 and 4 in Fig. 1. U1 and U2 are ripple counters whose input is a 555 clock. The first three stages of the counter drive a multiplexer/data selector, U4. Using the counter input, U4 repeatedly scans the memory (U3) outputs B0 and B7 for highs, which in turn appear on the output of U4. The last five stages of the counter provide the address inputs for U3. This input advances one count for each scan of the output bits. The result of this scheme is that the memory output is scanned sequentially (B0 to B7) for each word in order of address.

I used an NE555 for the clock and a pair of gates cross-connected as a flip flop to start and stop the clock. A pulse from the start circuitry sets the flip flop and starts the clock. When the end of the count is reached by U2, it triggers monostable U6A, which resets the counters and the start/stop flip flop. The inputs to U6A can be programmed to stop the counter after either 128 or 256 bits.

The start circuitry consists of monostable U6B and hold-off timer U7. When the input is grounded, it triggers the monostable through gate U9B. The pulse out of the monostable sets the start flip flop and starts the hold-off timer. The hold-off timer is an NE555 set for about 3 minutes. During this period, the monostable is kept from being triggered by further input keying.

When the timer releases, its output is capacity-coupled to the start flip flop. This pulse starts the identifier without restarting the timer. The output of the start flip flop is also used to turn on ½ of U11, which is used to key the transmitter.

A problem I encountered with this circuit was having

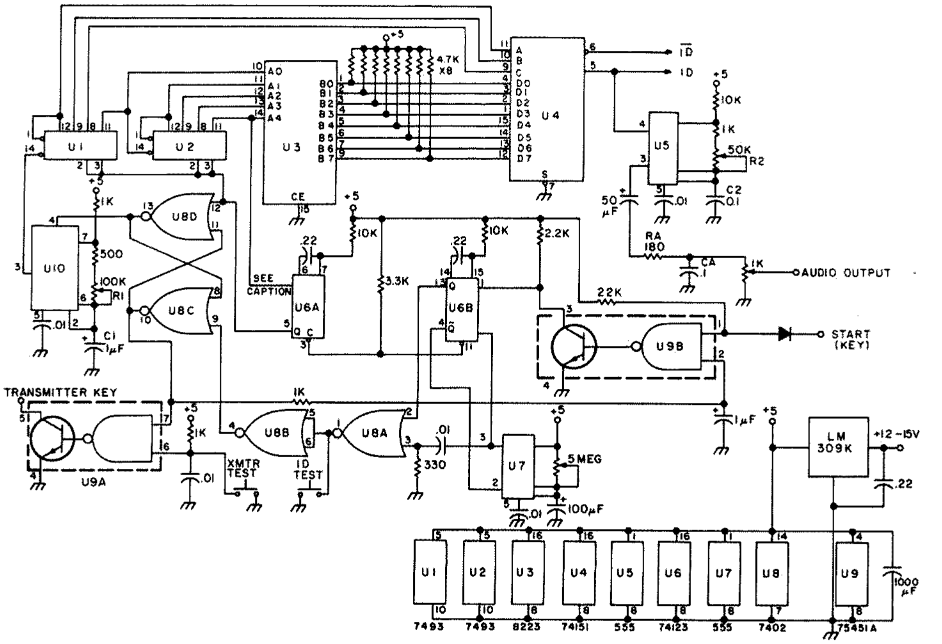


Fig. 1. Circuit of the identifier. For a 128 bit ID, connect U2, pin 11 to U6A, pin 10, and U6A, pin 9 to ground. For a 256 bit ID, connect U2, pin 11 to U6A, pin 9, and U6A, pin 10 to +5. R1C1 set the clock frequency and therefore the speed of the identifier. R2C2 set the tone of the audio output. Note IC numbers at bottom of figure.

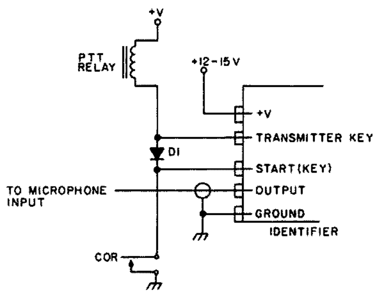

Fig. 2. Typical repeater interconnect with the identifier. The COR is in the receiver or terminal and the PTT relay is usually part of the transmitter power supply. Diode D1 must carry the current of the PTT relay.

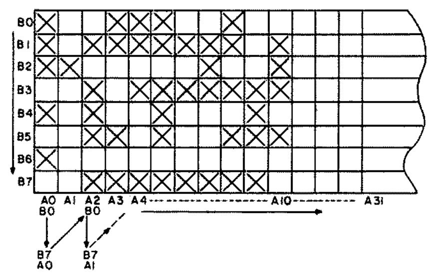

Fig. 3. This shows how the memory is programmed for "DE WR7ABC." An "X" indicates a programmed "1" and an open block indicates a "0". The memory is read from B0 to B7 and from A0 to A31, as shown by the arrows.

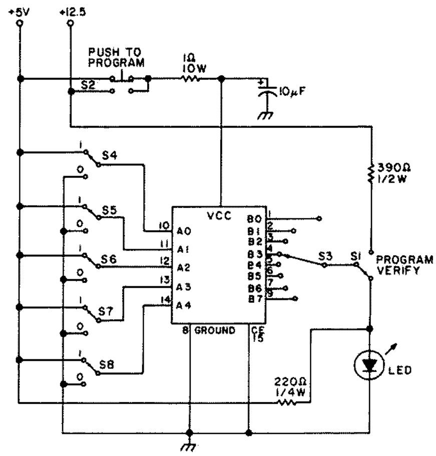

Fig. 4. A simple connection for programming an 8223 memory. The word address is selected by S4-S8. Each bit where a "1" is required is selected sequentially by S3. S2 is a push-button depressed momentarily after S1 is set to "Program."

the identifier re-keying itself and then identifying either continuously or once every three minutes. I wound up isolating the COR/PTT circuits with a diode, and using the second half of U11 as an input gate. This seems to work alright and not re-trigger.

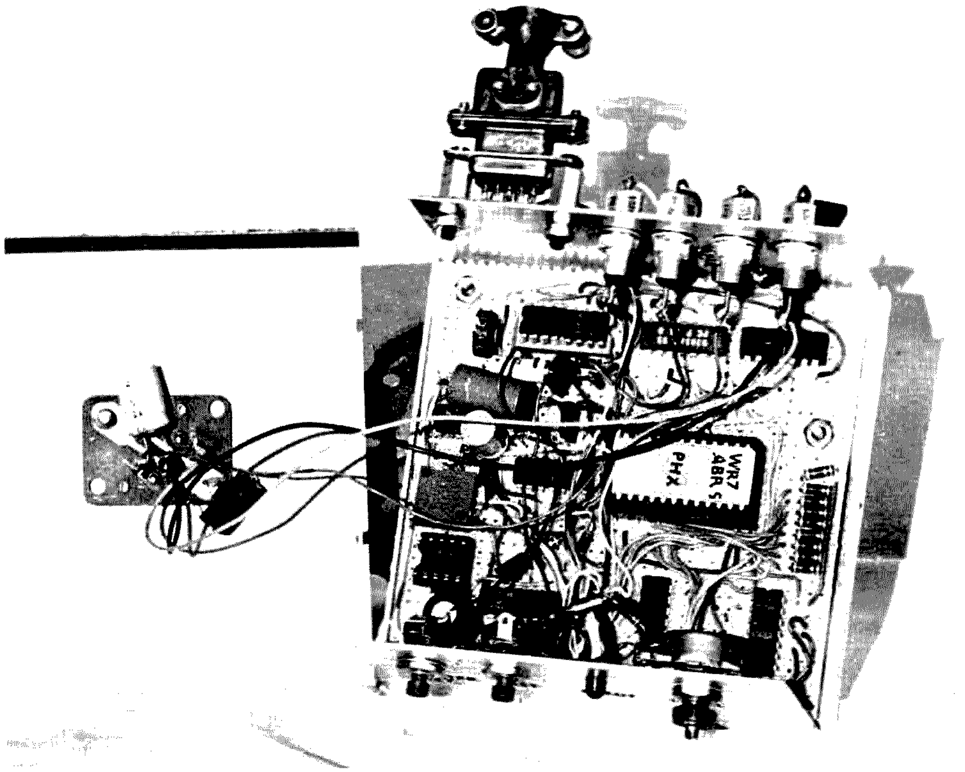
Like all TTL circuits, this one is somewhat rf sensitive. As a result of this problem, I have built the last two of these identifiers in aluminum boxes and brought the connections out through feed-throughs. This appears to solve the rf susceptibility problem.

I am using the logic output of U4 to key an NE555 audio oscillator, which is in turn sent to the microphone input of the transmitter through RA and CA, which roll off the audio above 3 kHz. The logic out of U4 could be used to CW key a transmitter through a relay or transistor if desired.

Operation

A typical interconnect is shown in Fig. 2. Diode D1 alows the output keying to ground the transmitter PTT line without grounding the identifier input.

I have one of these installed on a Motorola repeater with solid state control logic. On that repeater, I use the "Repeater PTT" line to key the identifier and I use the identifier output to key the "Local PTT" line. In this application the diode is not required, since the



Inside of the identifier. The construction is on perforated board with stick-on solder pads on the underside. This is a prototype unit and the large IC in the center is the PROM used instead of the 8223 shown on the schematic. On the rear of the chassis are filters to provide rf shielding of the leads. The plug on the left was an afterthought added to provide flexibility of connection. (In case you are wondering about the WR7ABR S PHX on the PROM . . . it is a 512 bit memory and has both ABR and ABS messages in it.) The wires and socket inside the top of the case are for the five volt regulator (LM309K).

"Repeater" and "Local" PTT lines are isolated.

Programming

I have suggested use of the 8223 type PROM because it is about the right size for a repeater ID, it is relatively inexpensive, and it is fairly easy to program. I used some larger (512 bit) memories for the units I built since they were available, but over half the memory is unused.

Setting up the program is straightforward. Fig. 3 shows "DE WR7ABC" programmed. The bits are used as follows: dot – 1 bit; dash – 3 bits, intercharacter spacing – 1 space; interletter spacing – 3 spaces; and word spacing – 6 spaces (a bit is a one, a space is a zero). A simple programming jig is shown in Fig. 4. This arrangement, although simple, is tedious because each binary address must be set in manually bit by bit (5 toggle switches). I have built a couple of programming rigs, and I suggest that the first step in sophistication be a thumbwheel address switch, preferably octal (as BCD to binary conversion is complicated). I have a jig for the 74186 type 512 bit memories, and used two BCD coded switches. I only use 0-7 on each and then do all my address setting in octal.

I must warn you, based on many wasted devices, that once you have set a particular bit in a PROM to a "1" it cannot be changed. The moral of this is that you must double-check your program and then do the programming slowly and very carefully.

Conclusion

This circuit has a lot of room for modification or change. For instance, the hold-off timer or re-trigger capability could be left out, or the time changed. The output of U4 is a TTL signal which, if used to turn on a transistor or relay, could directly CW key a transmitter. In my IDers I used 512 bit memories, and in one of them I have the capability of a TTL input which can change messages by switching halves of the memory.

As I mentioned, I can program the 54/74186 or MCM5003 type devices and will be glad to help people with information on programming. Please, however, if you request information, send an SASE. ■

The Amazing Inverted L

-- antenna for 20, 40 and 80m

Are you looking for an antenna that will outperform the usual horizontal dipole or trap vertical? How about an antenna that "works" just as well day or night on 80, 75 and 40, whether it's long or short skip conditions prevailing at the moment? Does the thought of a tendency to minimize signal fading (QSB) strike your fancy?

As illustrated, this antenna system requires a transmatch. Well, there go about half of the readers scrambling off to the next article. Those remaining might want to try something that is out of the ordinary, and certainly better than some of the simple coax-fed types.

If you examine Fig. 1 closely, you will see why this is called a *system* antenna. It consists of *all* of the ground reflecting screen wires *and* radials, as well as the simple antenna radiating element. All of this is what gives it the above average characteristics in overall signal strength.

Some Theory

Ideas for this system were heavily borrowed from articles in *73*, *QST* and *CQ* magazines (see references). The inverted-L is somewhat noted for a bit of diversity action. I enhanced this by extended (at least for 40 and 20) radials for the vertically polarized field, and a ground "screen," parallel to the flattop, for the horizontal field. This seemed to stabilize the overall response regardless of seasonal weather changes upon the earth in the immediate vicinity.

There seem to be several factors concerning signal fading. Some of these are changes in the skywave angle for transmitting and reception, as well as polarization shifts. This antenna has vertical and horizontal polarization, as well as high, medium and low radiation angles. At first one might think that "spraying" the rf in many directions of angles and polarizations will reduce the field strength in any one plane. However, *on-the-air results* dispel this notion. Instead, the opposite seems to be true over skip paths, with a *higher* average of signal strength as compared to ordinary dipoles and verticals, trapped or untrapped.

For 20 meters, the end-fed flattop will have several lobes at the medium radiation angles. The vertical section has a very low angle omnidirectional pattern. On 80 (75) and 40 meters, the flattop contributes to the high angles necessary for daytime use. The ground screen underneath it seems to give it short skip gain on 80 (75) and 40. A "barefoot" transceiver at 130 Watts average input on SSB usually sounds stronger than "normal," for example. The vertical section, along with the radials, takes care of the low angles for DX at night.

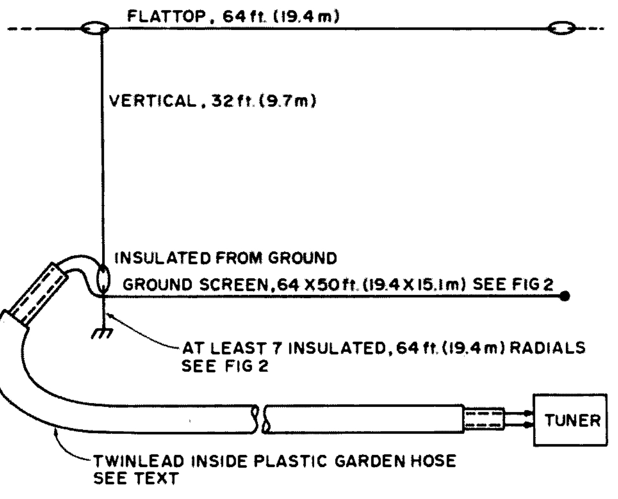

Fig. 1. Inverted-L system antenna for 80, 40 and 20, side view.

Details

When it comes time to put in the grounding system, don't conjure up frightening ideas of deep long trenches tearing up your dandelions. In fact, a deeply entrenched ground system will not work as well for this antenna as one that is above, on, or just below the earth's surface! My first ground system was simply lying on the snow-covered yard (and part of the neighbors' backyards). The antenna worked fine. When soggy spring season rolled around, I then took a large hunting knife and slit the spongy earth alongside the grounding wires and pushed them in about one inch. Now some of the radials were running just underneath my neighbors' well-manicured lawns!

One important item should be noted: *All of the grounding wires must be fully insulated, including the soldered joints.* Use a plastic type of insulated wire such as bell wire or hookup wire. The wire size is not too important. I used #20 solid insu-

lated hookup wire from Radio Shack. Electrical tape can be used to insulate the soldered joints and ends of the wires.

Don't skimp on the radials. Laying them at night under a full moon into a reluctant neighbor's turf can be exciting. If your own property cannot accommodate fully stretched-out radials, and that German shepherd next door is uncooperative, then at least lay them zigzag on your own lot as best you can. Don't shorten or reduce the number of radials.

The radiating element is #12 hard drawn copper enameled "antenna" wire. I suppose #14 will work just as well. I happen to like #12 for increased strength and possibly lower losses. The flattop section was suspended between two maple trees. The "free" end was stabilized with a rope and pulley affair hooked to the tree, using an old rock-filled paint can as a weight. My flattop was oriented east and west.

Transmission Line

Here is the part that looks questionable, but it seems to work. The whole thing is fed with 300 Ohm "balanced" line. I used the oval foam core type of UHF TV line. This handled my rig's 100 Watts output. For high power, I recommend the 300 Ohm transmitting twinlead. My feed line was run through a cheap discount store ¾ inch plastic hose, buried about 3 inches. I split the ground with a garden spade, and wiggled it back and forth a couple of times to spread the earth after each "stab." Yes, it's a bit tedious. When the feed line equipped hose was buried, I then stomped on the trench over the entire length, and after a couple of rain showers, it became invisible.

Be sure that *both* ends of the hose are well sealed. I used tape, and then smeared G. E. Silicone Seal over this. It has been my experience to find that "breather" holes are prone to suck in water. So seal both ends of the hose well, and don't worry about so-called "condensation." If you are using the air-core type of twinlead, then seal up both of these ends also.

Perhaps the 300 Ohm *openwire* (half inch) TV "ladderline" may also fit inside a large diameter hose. Its own insulators may help to keep it "centered" within. I have not tried this, but it's an idea that should have good power handling capabilities. The hose is used only for the underground portion of the transmission line, to help keep it dry and physically separated from ground.

I used both a balanced and an unbalanced type of tuner. Either one gave the same field strength readings at about one city block distance. Both of mine were able to load the system easily. Should you encounter a loading problem on one of the bands, try cutting or lengthening the feeder a couple of feet or so. Chances are you will still load up all right on the other bands.

If you are going to use an *unbalanced* type of tuner, make sure that the "hot" lead goes to the "antenna" side of the line, and the grounded part of the tuner goes to the "ground" side of the line. That may have been stating the obvious, but it is easy to get these feeder leads reversed to an unbalanced coupler. Yours truly did it, and the effect is sneaky. Reception seems fine at first; however, your transmitted signal is very weak!

Conclusion

This antenna system does not completely eliminate QSB, but if you compare it by switching it between an ordinary dipole and vertical (including the trap varieties), you will hear the differences.

One more thing. A "different" type of antenna makes a good conversation topic — especially if your signal is above normal for that particular time of day! ■

Battery Chargers Exposed

-- more than you probably wanted to know

A battery charger is one of the most common dc power supplies in use by the general public today. Chargers are available from Wards or Sears catalogs for charging auto batteries at charge rates from several Amps to over 100 Amps. Also in common usage are the small battery chargers designed to recharge a variety of cordless appliances, from toothbrushes to electric carving knives. These smaller chargers are usually designed to charge tiny nickel-cadmium (nicad) batteries

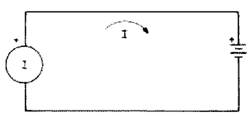

Fig. 1. Basic charger using constant-current generator.

that are more or less permanently built into the appliances. More recently, the nicad battery has been supplemented by another "sealed" type of rechargeable battery: the "gelled-electrolyte" lead-acid battery. "Gell-Cell" is Globe-Union's trademark for such a battery. The gelled-electrolyte lead-acid batteries are generally of larger physical size and weight than nicads, and are used in portable transceivers,

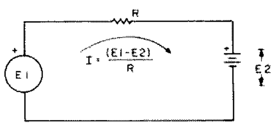

Fig. 2. Approximation of constant-current charging using constant-voltage generator and series resistor (R).

standby lighting systems, intrusion alarm systems, and similar applications.

There are differences among chargers for use with conventional lead-acid batteries (such as used in autos), and still other differences among the small chargers designed for the "maintenance-free" batteries. We will look at a variety of chargers, to see what they basically do, and to see how they differ.

The main function of *any* battery charger is to cause *current* to flow back into a battery in the opposite direction from which current flowed during discharge. Batteries, when used properly, are relatively constant-voltage devices, so the

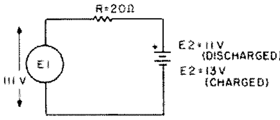

Fig. 3(a). With E_2 discharged, $I = (111-11)/20 = 5$ A; with E_2 charged, $I = (111-13)/20 = 4.9$ A.

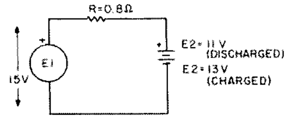

Fig. 3(b). With E_2 discharged, $I = (15-11)/0.8 = 5$ A; with E_2 charged, $I = (15-13)/0.8 = 2.5$ A.

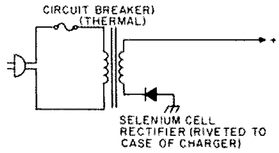

Fig. 4. Typical inexpensive commercial battery charger.

most meaningful measurements in battery charging are made in *Amperes.* The current for charging can come from a number of sources; the commonest source, today, is a low voltage secondary transformer and solid state rectifier. In years past, motor generators, and low voltage transformers with older types of rectifiers, were extensively used as chargers. The principle was always the same: Force *current* back into the battery to charge it.

The basic battery charger, shown in Fig. 1, uses a current source. Since current sources are not as common as voltage sources, an approximation to a current source can be made as shown in Fig. 2. By making E_1 *large* compared to E_2 (the battery voltage), essentially constant current will flow during the battery charging cycle, even though E_2 rises slightly as the battery nears full charge. To see quantitatively how this works, let's take the two examples shown in Figs. 3(a) and 3(b). In both cases, we'll assume that the uncharged

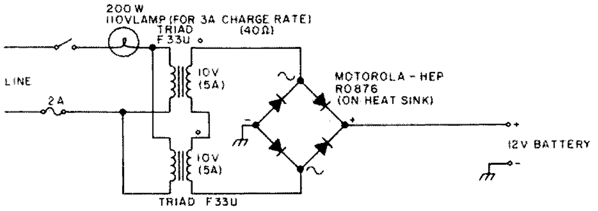

Fig. 5. Simple battery charger with current-limit resistor in transformer primary.

(lead-acid) battery starts with an E_2 of 11 volts, and that E_2 at full charge rises to 13 volts. In Fig. 3(a), the current at the start of charge is 5 Amps and at the end of the charge cycle is 4.9 Amps. That is, the charge rate has only changed 2% during the charging cycle.

In the example in Fig. 3(b), however, current undergoes considerable change during the charge cycle. As in the first example, the charge starts out at 5 Amps, but drops to 2.5 Amps at the end of the cycle. This latter case is typical of most inexpensive battery chargers on the market; the number of Ampere hours put into the battery is difficult to calculate, however. This latter case is a simple form of "tapered charging" and is actually a reasonable approach, especially if you're the type who forgets to turn off the charger. The smaller end-charge current will not electrolyze away as much water from the battery as fast as with constant-current charging (if the charger is left on too long).

Modern commercial battery chargers, available from auto supply stores and mail order catalogs, are generally of the form shown in Fig. 4. Selenium disc rectifiers are still used because they have a rather large forward voltage drop, and so can make it unnecessary to use a dropping resistor. Another trick used in commercial battery chargers is to wind the transformer so as to have a relatively large equivalent secondary leakage inductance, and thus eliminate the need for a current-limiting resistor.

In older types of chargers, copper-oxide-disc and tungar-bulb rectifiers were used; these rectifiers also had considerable forward drop. Older chargers can occasionally be retrieved from the "back of the garage" and returned to use by replacing non-functioning rectifiers with modern silicon rectifiers. However, when doing this replacement, be sure to add some current-limiting resistance to make up for the higher efficiency of the new diodes. The value of resistance can readily be determined by charging a discharged battery, starting with a reasonable guess as to resistance value, and watching the ammeter. One can even add the current-limiting resistance in the primary of the charger transformer, if that's easier.

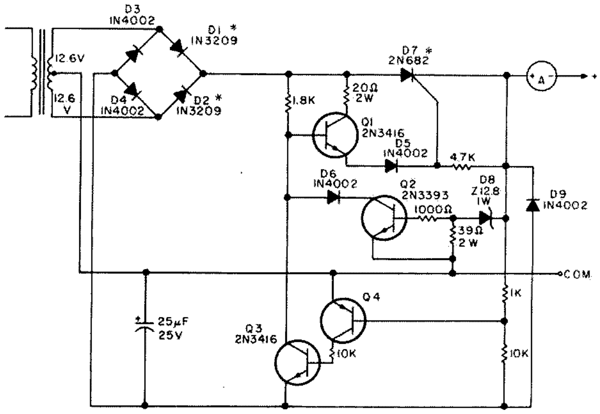

*Fig. 6. Heath GP-21. *All on one heat sink.*

Primary current-limit resistors are, of course, higher in resistance than those in the secondary circuit. A home-made charger using a 200 Watt light bulb as such a primary resistor is shown in Fig. 5.

In recent years, there has been progress in making electronically-controlled chargers that charge conventional lead-acid batteries completely automatically. Such chargers are now commercially available, and you may connect

your battery to the charger and essentially forget it. Such an automatic charger is the Heathkit GP-21. The GP-21 is not only self-controlling, but is protected against shorting the battery leads together and reversing the battery leads. Either of these two operator errors produces no sparks or opening of breakers, but simply non-operation. The Heathkit GP-21 is shown in Fig. 6. Note that Q3 and Q4 are involved in the lead-shorting and reversal protection; the basic charger can be simplified (for circuit understanding) to that of Fig. 7. Whether the GP-21 charges the battery depends on whether the 12.8 volt zener (D8) conducts; that is, whether the battery terminal voltage is over 12.8 volts. If the battery voltage is below 12.8 volts, the battery needs charge, D8 does *not* conduct, Q2 is "off," and Q1 is allowed to pass full wave rectified 60 Hz via R1 and D5 to the gate of D7. Thus D7 turns on (at 120 Hz rate) to pass current to the battery. If, on the other hand, the battery voltage is above 12.8 volts, D8 conducts, causing Q2 to be "on," which clamps the base of Q1 to ground (via D6) and full wave rectified 60 Hz is *not* passed via R1, Q1, and D5 to the gate of D7. So in this second case (with a "charged" battery, with terminal voltage over 12.8 volts), D7 is prevented from passing additional current to the battery.

The circuit of the Heath GP-21 could probably be duplicated by many home-constructors, but the 12.8 volt zener is a nonstandard value. The cost of parts would almost certainly exceed the Heathkit cost, however. I built an automatic charger that has performance similar to that of the Heath GP-21. This charger was built to use two 6.3 V, 10 Amp, filament transformers as the main current source; such filament transformers are usually pretty common in ham "junk boxes." The feature of the charger shown in Fig. 8 is that an LM319D dual comparator is used to sense "end-of-charge" battery voltage and to provide "reversed charger leads" and "shorted charger leads" protection sensing. In this circuit, the "end-of-charge" voltage is *adjustable* by means of a small 2k trimpot. The LM319D uses a ±15 volt supply which is provided by a Triad F40X, bridge rectifier, and Raytheon RC4195 dual regulator IC. A fraction of the +15 volts regulated voltage (as voltage-divided by the two 6.2k resistors in series) is used as the voltage reference against which the lower comparator compares a fixed fraction of the battery voltage. The function of the upper comparator is to sense a "reversed leads" or "shorted leads" condition. In order to facilitate construction of this charger, the control circuitry has been laid out on a PC board, shown in Fig. 9. The larger components, and those on the heat sink, are mounted off the PC board.

The nicad battery was one of the first "maintenance-free" rechargeable batteries introduced in the U.S. It is quite different from the lead-acid battery, in that the electrolyte is a strong base (potassium hydroxide or sodium hydroxide) instead of an acid. The plates are made of nickel hydroxide (positive) and cadmium (negative). Although nicads can be made with conventional filler caps, so that they may be maintained like auto batteries, most of the small ones are of the "sealed" type. These "sealed" nicad batteries are the ones most used in hand-held transceivers and small appliances. The electrolyte in such batteries is held in a separator between the positive and negative plates, which is also gas-permeable. The gas-permeable separator

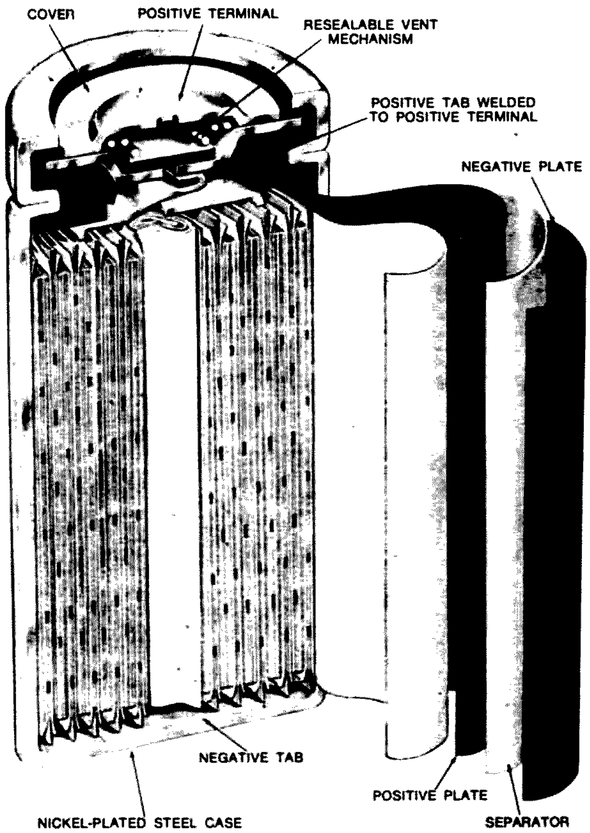

Fig. 10(a). General Electric nicad cell structure.

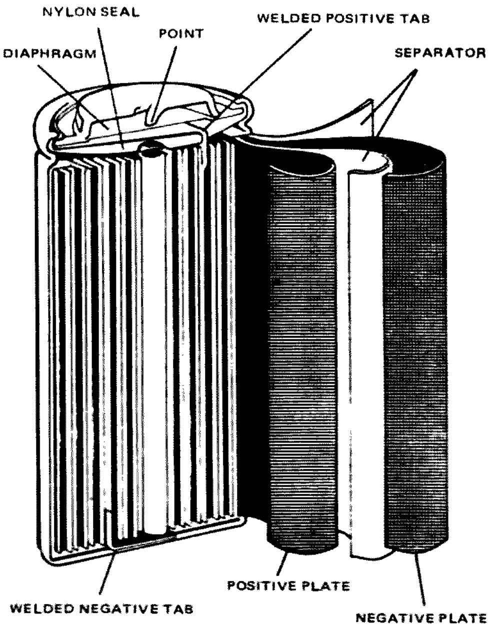

Fig. 10(b). Sonotone nicad cell structure.

absorbs oxygen which the battery liberates when it is over-charged. Almost all "sealed" nicad cells have a safety release value, however, so that in extreme overcharge conditions they won't explode. Some of these valves are of the resealing type and some are not. Fig. 10 shows the overpressure vents of the Sonotone and G.E. units. The point here is that even "sealed" nicads may vent gasses, if severely mistreated.

The "sealed" nicad is generally charged with a constant-current type of charger, with the addition of a voltage limit across the battery. This sort of charger can be relatively simple, as several construction articles in the amateur literature have shown.[2,3] In Fig. 11, three approaches to the constant-current, limited-finish-voltage charging method are shown. The first method relies on the nonlinearity of light bulbs to approximate constant current (the resistance of a light bulb decreases with decreasing voltage across it). The light bulb charger, Fig. 11(a), is similar to one shown in reference 2. Fig. 11(b) shows the FET approach of reference 3; the FET has an inherent constant-current characteristic which is utilized in this charger. The large number of FETs is required because it is desired to utilize the inexpensive plastic types. Since the nominal I_{dss} of the HEP-802 or F 0015 FETs is nominally 2 to 20 mA, some "picking and choosing" must be done. Units with I_{dss} of 8 to 15 mA will be considered usable in this circuit. The sum of I_{dss} for units Q1 and Q2 will be 15 mA, and the sum of I_{dss} for units Q3 through Q6 will be 35 mA. A switch is used to connect Q3 through Q6 for a total current of 50 mA during "charge"; when this switch is opened, the current drops to 15 mA for "float" or "trickle" charge. The zener diode D1 limits the "finish" voltage, as in Fig. 11(a).

The charger in Fig. 11(d) produces constant current by means of a simple transistor circuit, in which the current is adjustable by the user by means of R_1. The "charge-float" switch is closed during "charge" to raise the value of constant current. As in the chargers of Figs. 11(a) and 11(b), a zener diode is used to limit the "finish" voltage.

All of the chargers in Fig. 11 were intended to be used with a ten-cell pack of nominal 12.5 volts, as used in many transceivers. The individual cells in such a pack are of the AA size (penlite) and have about 400 mAh (milliamp-hour) capacity. The Sonotone S-101 or General Electric XGCF450ST are representative units of this type cell. As a general rule one charges at a rate that is 1/10 the mAh rating of the cell or battery. That is, for a 400 mAh battery, we should charge at a rate of about 40 mA. Such a charge rate would appear to fully charge a 400 mAh battery in 10 hours, but usually nicad batteries are overcharged at least 25%, as recommended by the manufacturer. No damage is supposed to occur if longer overcharging occurs, but most battery manufacturers recommend a much lower "float" or "trickle" rate after the battery has been overcharged about 150%. It is possible to use higher charge rates with nicads, especially if special types are used, and accurate timing is made certain. For example, in an AA cell, General Electric offers the XKCF450ST, which will take a 150 mA overcharge rate (more than 3 times normal). In any case, the recommended rates of the manufacturer should be consulted before any rapid charge mode is tried.

Although it has only indirect connection with nicad battery charging, the discharge cycle is also quite important, too. In series groups of nicad cells, the individual cells do not always hold equal charge, and the one which discharges first may be run down into "cell reversal." This is considered bad form, and can destroy the reversed cell. One way to help avoid cell reversal is to make sure that the system powered by the nicad battery stops its drain when the battery voltage drops to 1 volt per cell. That is, for our 12.5 volt pack, operation

would be stopped at 10 volts, and a charging cycle started. A more detailed article on nicad batteries is presented in reference 4, for those interested in all the tricks.

The lead-acid, gelled-electrolyte battery has been introduced more recently, and is designed to be a lower cost "maintenance-free" unit. The gelled-electrolyte battery is similar to a standard lead-acid battery in per-cell-voltage and in the chemical reactions inside it. The electrolyte is held in a gell, however, so the battery may be used in any position, and there are no filler caps. The gelled electrolyte batteries have no "cell reversal" problem nor the "memory effect" characteristic of nicad batteries. They do vent during normal overcharge, and usually have resealing vent valves for this reason. This venting causes a loss of the water in the gelled electrolyte, which cannot be replaced, so the cells do have a limited life, depending on how much overcharge is used. The recommended method of charging one such gelled-electrolyte battery, the Elpower "Solid Gell" battery, will serve as an example of how at least one manufacturer feels it should be done. The Elpower EP1230A is a 12 volt, 3 Amp-hour unit and is charged at a maximum current of 0.45 Amps until a battery voltage of 14 volts is reached. The voltage is then held constant at 14 volts until the charge current drops to 0.040 Amps. At this point the charger is disconnected or switched to "float." The "float" mode keeps 2.2 volts per cell across the battery, or 13.2 volts for the EP1230A.

The charger in Fig. 12 is designed to charge a 12 volt, 3 Ah gelled-electrolyte battery, such as the Elpower EP1230A. It is essentially a constant-voltage regulator with current-limiting as designed around a National LM305H, with the usual PNP-NPN pair to increase current capability. The constant output voltage is adjusted by means of the 5k trimpot and the current limit is controlled by the value of the 0.68 Ω resistor. This 0.68 Ω resistor is actually a 1 Ω and a 2.2 Ω half-Watt resistor in parallel. All the circuitry above the dotted line is added to the standard regulator to accomplish the special gelled-electrolyte charging requirement. This added circuitry consists of 1N4454, LED, LM311H voltage comparator, 2N4302, FCD810 optocoupler, six resistors, and two pots.

The way that the charger circuit works is as follows. When you connect a discharged battery across the output, the battery will tend to draw unlimited current, since the supply has constant voltage output, and the battery voltage is (presumably) lower. The current-limiting function of the LM305H immediately comes into effect, however, and only 0.45 Amps is passed, so the output voltage drops to that of the battery. As the battery charges (at the constant-current rate of 0.45 Amps), its terminal voltage rises slowly to 14 volts, but cannot rise above this voltage because of the *voltage* regulating action of LM305H circuit. So when the battery voltage gets up to 14 volts, the charging current starts to diminish. During the initial constant-current and constant-voltage phases of charge, the voltage at point "A" is higher than that at point "B," both with reference to point "C." The voltage "BC" is constant because of the regulator formed by the 2N4302 and 1N4454. As charging current through the 0.68 Ω resistor drops, the voltage "AC" drops until it is no longer more positive than voltage "BC." At this point the LM311H output changes from "high" to "low," which turns on the LED *and* the LED inside the optocoupler, FCD810. This in turn causes the optotransistor in the FCD810 to saturate, and connects the 10k and 250k pot across the LM305H sensor-divider. The constant-voltage output of the LM305H regulator is thereby dropped from +14 to +13.2 volts.

Since there are several adjustments on the charger, the setup is somewhat complicated. First, pull the FCD810 out of its socket, and with a voltmeter across the charger output (no battery, yet), adjust the 5k trimpot for +14 volts output. Then add a 350 Ω, 25 W rheostat across the terminals and decrease resistance until regulation is lost (as indicated by a drop in output voltage as read on the voltmeter). This point should correspond to 0.45 Amps on the ammeter; if it does not, the size of the 0.68 Ω current-sense resistor should be adjusted. The FCD810 should now be restored to its socket and the 350 Ω rheostat increased in resistance until the red LED lights. This should correspond to about 40 mA on the ammeter; if not, the 500 Ω trimpot should be adjusted until the proper trip point is achieved. Since the LM311H has deliberately had hysteresis added to its circuit (the 3.3 meg resistor), it will be necessary to adjust the 350 Ω load down in resistance considerably until the circuit untrips, as indicated by the LED going out. The 350 Ω rheostat is then decreased in resistance to find the new trip point, and so on.

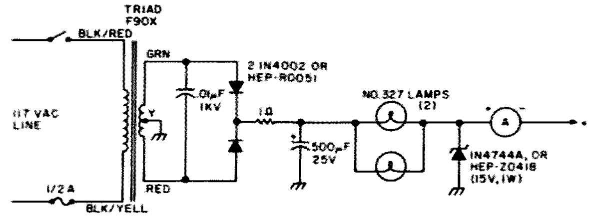

Fig. 11(a).

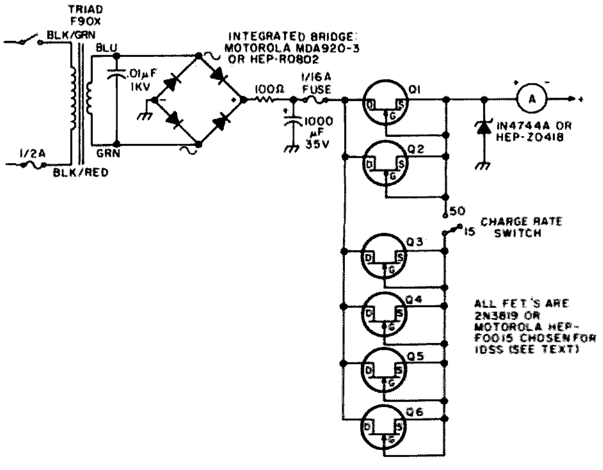

Fig. 11(b).

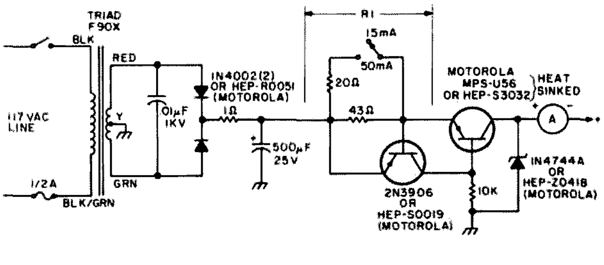

Fig. 11(c).

After a satisfactory trip point of about 40 mA is found, the float voltage may be set to approximately 13.2 volts. This is done with the 250k trimpot.

Finally, there is one awkward condition that may occur when charging a partially discharged battery. If the discharged battery does not draw enough current from the charger to "untrip" the LM311H, the output voltage will stay at +13.2 volts. This will not do much charging of the battery. A push-button switch and 50 Ω, 5 Watt load are provided to "untrip" the circuit and move the charger to +14 volt output state. The red LED indicator is "on" when the charger is in the +13.2 volt state and "off" when the charger is in the +14 volt state.

In this article we've attempted to cover the several common rechargeable batteries and their chargers. Specific charger circuits, both conventional and automatic, have been shown. Hopefully, enough details of circuit operation have been given to enable the astute experimenter to redesign the circuits for the particular battery he needs to charge. The references appropriate to each charger should be consulted, of course, to glean additional details when modifying these circuits. In addition, it cannot be emphasized too greatly that the manufacturer's recommendations on a particular battery should be followed regarding both charge and discharge cycles! ■

How Do You Use ICs?

-- part III

The ICs (Integrated Circuits) used in frequency dividing circuits are one group of ICs that can restore your faith in the IC dream. While many of them were not primarily designed for just that purpose, they find wide application in many IC projects.

They are probably the easiest circuits to hook up and use, and in the applications to be shown, require no external parts. While there are several which are commonly known and used, there is one in particular that stands out as perhaps the most frequently used: the 7490 Decade Counter.

The 7490 is used two ways in a frequency counter. One section of the counter uses it as part of the actual counting circuit, where it connects with the driver that runs the numerical readout. Using a slightly different hookup of the same device, it is used in the timing chain to divide the basic "clock" or oscillator frequency to the desired time.

This is the hookup to be discussed here. It is so commonly used for all clock, timing or frequency dividing circuits that once it is learned, whole sections of equipment will fall into place.

Depending on how it is hooked up, the 7490 will divide the input frequency to it by two, five or ten. It will do this with any frequency up to the device's frequency limit, about 20 MHz for the 7490, and higher for the high speed versions of the 7490.

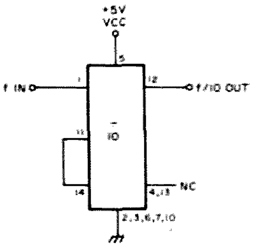

Fig. 1. 7490.

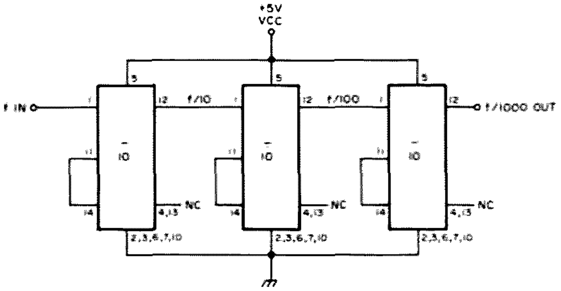

Fig. 2. 7490.

It is remarkably uncritical to use. The only basic requirement for it, and the other divider ICs, is to feed it a square wave. If you feed it with a 7400 oscillator or something similar, this will be taken care of automatically.

If you are using a sine wave source, you will have to run it through a clipping circuit. The IC oscillator feed is the more common by far. The signal is usually fed from one section of the 7400 used as a buffer stage between the oscillator and the divider, but this is not always done.

Once the basic patterns of hooking up the 7490 as a frequency divider are learned, you will have them, and it is just a question of applying them to your use.

Fig. 1 shows the divide by ten circuit. Simple, isn't it? All you do is ground pins 2, 3, 6, 7 and 10, connect pin 11 to pin 14, feed the input signal to pin 1, and take the output from pin 12.

As Fig. 2[1] shows, adding stages is just a matter of repeating the same thing, with the output of one stage going to the input of the next.

While not always used, it is not uncommon that there will be a bypass capacitor connected between the Vcc pin and ground with this and the other divider ICs. One is used for each IC in the chain. The value is usually 0.01 to 0.1 uF.

To get divide by two and divide by five, it helps to understand how divide by ten is arrived at. The 7490 actually starts off by dividing by five and two, the two being combined to get divide by ten.

Pin one is the divide by five input. The output is at pin eleven. The divide by two input is at pin fourteen and the output at pin twelve. For divide by ten, the divide by five output is connected to the divide by two input.

Without this connection between pins eleven and fourteen, the two sections are available for separate use. An

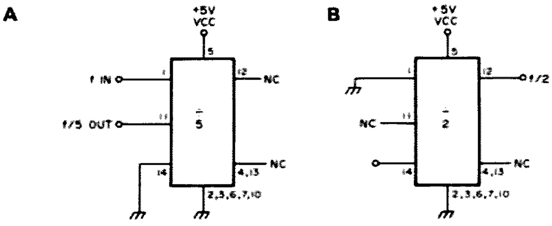

Fig. 3. 7490.

input to pin one will yield divide by five output at pin eleven. An input at pin fourteen will yield divide by two output at pin twelve.

If both outputs are desired, both inputs can be connected to the frequency source and the two outputs will be available at their respective output pins.

Examples of these hookups are shown in Fig. 3, A and B, and Fig. 4. That is all there is to it. Then it is just a question of deciding what frequency divisions you want, block diagramming it and assembling the needed ICs.

Switching is not critical, and it is easy to get a wide variety of combinations that will serve many purposes. Some forms of these hookups are the backbone of the various counter and clock timing circuits. Learn them and a whole section of the more complex equipment is yours.

Besides frequency counter use, this same type of circuit is used for a frequency calibrator (secondary frequency standard) for receivers and transmitters.

The output from an IC buffer stage is usually connected to the receiver. A switching arrangement provides a choice of available output frequencies, such as 1 MHz, 100 kHz, 10 kHz, 5 kHz, 2 kHz and 1 kHz.

For counter use, it is the final output signal gating the counter part of the circuit which determines what the frequency range is that is actually counted: MHz, kHz, Hz or whatever degree is desired.

Considering that the 7490s can be bought for as low as about 50¢ each, the temptation is to build a counter to read your frequency to maybe a few thousandths of a cycle – maybe even better if you get a good deal on the readouts.

Unfortunately, it just doesn't work that way. There is a law of diminishing returns that gets in the way. In this case, it is a matter of time.

Starting with a 1 MHz crystal, you have a signal of 0.000001 second per cycle. Six 7490s will give you a one cycle per second pulse.

If, for example, you wanted to read an audio signal to better than one cycle per second, you would have to have a slower timing pulse. This is easy to do by adding another divide by ten stage, but this is where the trouble starts.

One more stage makes a pulse that is ten seconds in length. Two stages would be needed to read an audio signal to within hundredths of a cycle per second.

This means one cycle per hundred seconds pulse. That works out to one minute and 40 seconds. Add two more decimal places and you will wait 1000 seconds which is over sixteen minutes.

Even if your counter had timing pulses of that duration, over a period of that long, a high frequency oscillator is going to have some drift. It will be in cycles or tens of cycles per second.

Even if your counter could read the actual frequencies, past a certain percentage of the frequency the readout would be a blur because the actual frequency would be instantaneously changing.

In practice, quite a bit before you reach this problem, you will run into the actual accuracy of the crystal used in the timing chain.

There is a limit to the overall accuracy to which you will be able to set and maintain the calibration of your oscillator, which is the overall determining factor in how accurate your counter will be.[2]

If the tolerance of your crystal is such that the best accuracy you can expect at two meters is within a few hundred cycles, it will add nothing to be able to read within cycles per second.

With the simpler circuits, you may have an actual accuracy to within a kHz or so at those frequencies, so the additional digits of readout may show you down to cycles per second and your answer may be off by kHz.

While you can read your transmitter frequency to within a very close tolerance (up to 30 MHz or so), there comes a point where a usable reading ceases to exist. For normal use, most inexpensive counters will put you within 100 cycles and may even get within ten.

Beyond that it begins to become impractical to get a figure that is usable with simple equipment. Of course, with audio frequencies you may be able to go down to parts of a cycle, but still there

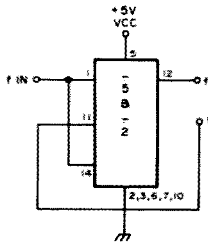

Fig. 4. 7490.

comes a point beyond which there is no usable advantage.

While the 7490 is the most commonly used divider IC, there are others common enough to warrant knowing about.

The 7493 Four Bit Binary Counter will give divisions by two, four, eight and sixteen when it is connected as a frequency divider.

The technical data lists two ways of hooking it up. The first, shown in Fig. 5A, is as a four bit binary counter with "A" output (pin 12) connected to "B" input (pin 1). This is shown as giving divisions of 2, 4, 8 and 16 at outputs A (pin 12), B (pin 9), C (pin 8), and D (pin 11) respectively.

The second hookup does not use the A section, but feeds the input directly to the B input as shown in Fig. 5B, getting divisions of 2, 4 and 8 at B, C and D respectively.

While the above information comes from the technical data on the device, Fig. 6[3] shows an actual circuit taken from a piece of equipment.

Here the device has been adapted to provide divide by six operation, which shows you how much respect some people have for what the device is supposed to be able to do.

The next device of interest is the 7492 Divide by Twelve Counter. This also has two

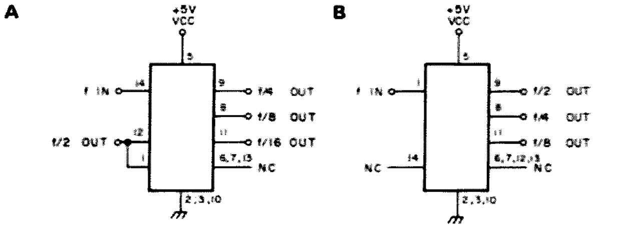

Fig. 5. 7493.

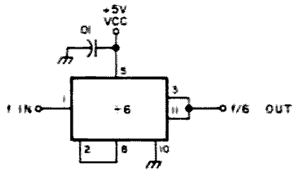

Fig. 6. 7493.

ways of hooking it up for different frequency divisions.

Connected as a divide by twelve counter (Fig. 7A), output A is connected to the BC input, giving divisions by 2, 6 and 12 at A, C and D respectively.

If A output is not connected and the signal is fed directly to the BC input, you get division by three and six at C and D outputs respectively, as shown in Fig. 7B.

These appear to be as easy to hook up and use as the 7490. You just decide which of these divisions you require and work out the device configuration to do it. They hook up like building blocks.

There does not appear to be a consensus about what to do with the unused section of a divider IC when you only need one part of it. This is quite common in practice where you only need one section to get the required division.

In many instances it may be safe to just leave the entire unused section floating, but this might be able to cause a false pulse or other unstable operation.

You can probably tie the unused input to the input of the section you are using and ignore the output from the unwanted section, but the safest method might be to tie the unused input to the Vcc source through a 1000 Ohm resistor.

Some of the circuits show the unused section's input connected to ground, but this may not be safe for all of the devices.

While not usually referred to as frequency dividers, there are flip flop ICs which can perform the same function. They can easily be applied to a circuit to get the required frequency division. Two such circuits are shown for illustration.

The first is the 7473 hooked up to provide divide by four output. In this case, pins two and six are connected together and give a switching feature to control the stage (Fig. 8[4]).

The second, using a 7476 (Fig. 9[5]), is quite straightforward, but there is one unusual feature. Notice that the device is split into two separate rectangles and that inside each are letter designations as well as the pin numbers outside.

For simplicity, most amateur schematics only make use of the pin numbers or sometimes use the computer schematic symbol for easy identification of the device.

Since these are computer circuits, they have a computer terminology not only for the device function, but also for the names of the various connections within.

The letters refer to those names. As they are not really needed for our purposes, they will not be explained. It is unlikely that you will find a schematic where the letters will be given without the pin numbers.

It is still easy to see that the diagram refers to just one device even though it is drawn in two parts.

In the unlikely event that you do find a schematic that just gives the letter names, you will have to refer to the technical data for that particular device.

Somewhere in there should be the full drawing of both sections giving the letter names and the pin numbers for each pin.

These circuits have been shown to gain familiarity with such circuits. As can be seen, they are all very similar in their lack of complexity.

These can actually be thought of as practical building blocks. These, or similar circuits, can usually be lifted bodily from one piece of equipment and used for the same purpose in another.

By keeping a card file of such circuits, you will build a reservoir of them that can be tapped when needed for your own equipment. Just determine what frequency divisions are necessary and pick the circuits needed from your file.

As you run across other devices used for this purpose, you should have no trouble in recognizing the complete circuit and isolating it schematically for your file. ■

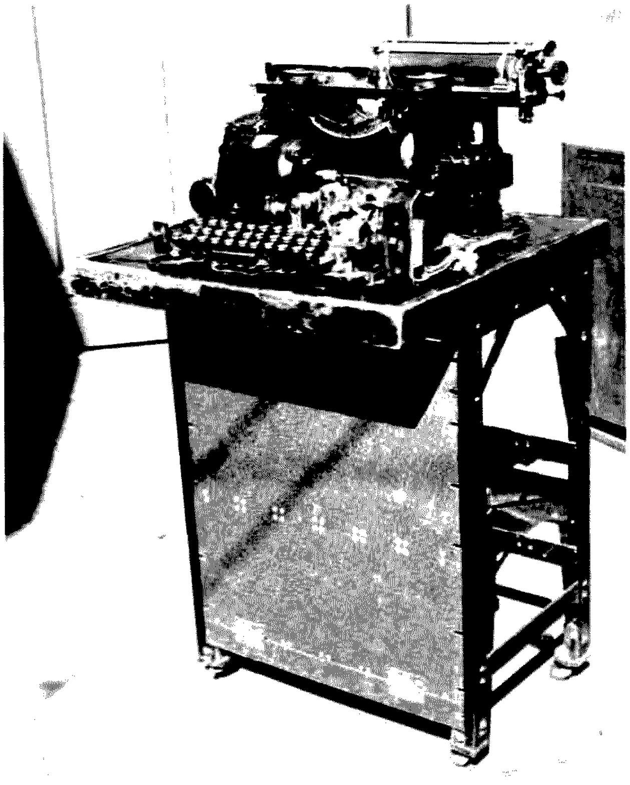
Thirty Years of Ham RTTY

-- from the Model 12 to the microprocessor

Amateur radio teletype got its start in 1946 soon after the two meter amateur band was opened.

I remember getting word that 2½ meters was open along in September 1945. I was teaching radio and radar at the submarine base in New London at the time, and it took but minutes for me to dash up to the lab and put a rig on the air and start making ham contacts. The next weekend I drove home to Brooklyn and picked up my homemade battery transceiver . . . built pre-war out of *Radio* magazine. How many of you have seen copies of *Radio*? It was the *class* magazine of the 30's and made us all wonder what was wrong with *QST*.



The old Model 12 "warhorse" Teletype machine . . . the printer that got amateur radio teletype started back in 1946.

Ten meters was opened, as I recall, along about late November 1945, and the 2½ meters was changed to 2 meters in December 1945. Within weeks W2BFD was going hot and heavy with his audio frequency shift radio teletype up on 147.96 MHz and slowly gathering a group of interested pioneers.

The equipment in those days was a Model 12 Teletype machine with good strong electromagnets for each of the five pulses of the Baudot code and one whopping magnet to make the selected key print. Signals were sent serially and converted to parallel with a mechanical distributor on the keyboard. The whole works made a terrible racket and a lot of radio hash.

My own interest in RTTY was sparked in 1948 when I heard a peculiar tweedling of tones on the high end of two meters. It turned out to be John Williams and a dozen or so other RTTY amateurs hunting and pecking away at each other.

Within a few weeks, I had my own printer and had put together a tone generator and demodulator, complete with autocall circuits, and was joining in the fun. I also tried it out on 11 meters and made quite a few good contacts with W6s, including W6NRM, one of the more important RTTY pioneers. On 80m I had to use make-break keying since FSK was not yet permitted, but even so quite a few contacts were made, even out to California.

The two meter distances between stations were such that beams were required to make most of the contacts . . . and that meant that many operators were unable to copy what was going on. John solved this by setting up a repeater on top of the Municipal Building in downtown Manhattan. I won't soon forget the project as I was the one who climbed out on that copper roof one midnight in the middle of a snowstorm to set up the antennas. In case you wonder how I managed to hang on to the steep roof (you can see it as you drive across the Brooklyn Bridge or the Manhattan Bridge), there are little pegs sticking up, and these provided hand and foot holds. If it hadn't been the middle of the night I'd never have made it . . . one look down and I'd have had it.

The repeater made it possible for all of the RTTY gang to talk with each other. Most of us were using automatic circuits which made it so messages could be left for us when we were not present. Often I would leave my machine on short start, which would permit it to copy everything on the channel, and I would come home after a day or two away to find maybe fifty feet of rag chewing and gossip piled up on the floor.

Some stations were set up for automatic roger. This was a neat little circuit which would turn on the other fellow's rig and send back a couple of bleeps to let you know that your message had been copied. It wasn't exactly legal, but it was a good pioneering effort. It is a pity that the FCC has historically made it so difficult for amateurs to experiment and pioneer things. One wonders what might have been developed if amateurs had been permitted to have their head. Considering the resistance of the FCC to pioneering and their molasses-like acceptance of change, it's a wonder we've done as well as we have!

Speaking of resistance to change, we started to work toward getting the FCC to permit FSK on the low bands in 1950 ... it took several years before FSK was finally permitted. In all fairness to the FCC, the time it took was not so much a result of their slowness as the bitter fight put up against RTTY by the ARRL. The League countered every effort of RTTYers with legal efforts to stop them. Fortunately for the RTTY group, the ARRL was in very poor favor with the FCC. Despite their massive efforts, the ARRL racked up quite a few years when every single petition they put in was refused by the FCC and every one the ARRL fought was accepted.

This was the period when the Novice license was set up (with extreme resistance by the ARRL), and the Tech license. The chairman of the FCC was a ham and he was well aware of the attitude of ARRL HQ toward the hobby ... and he was determined to help amateur radio progress despite Budlong and Segal.

The ARRL didn't get a friendly reception in Washington until well after the uprising against Budlong and Segal led by Mort Kahn W2KR, when Budlong found himself suddenly "retired" and Segal replaced by Booth.

Here's Wayne in 1952. Watching are Faye Emerson, Bill Halligan, Skitch Henderson, Conrad Nagle and Herb Sheldon.

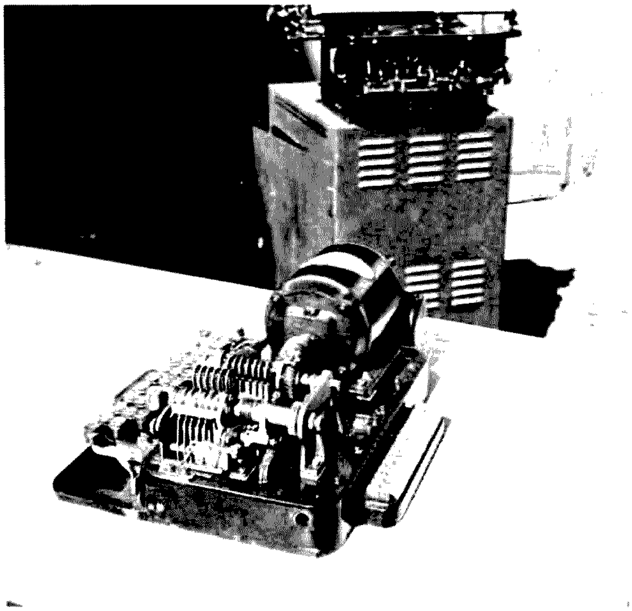
Insiders, well aware of the utter contempt ARRL HQ had for their sheep-like members, found things somewhat improved under Huntoon (Kahn's protégé). Hopefully someone will someday write a true history of amateur radio and put ARRL in its real perspective.

In the late 50's when the Model 15 printers started becoming available at reasonable prices, the Model 12s were retired. The Model 14 strip printers never got to be very popular ... hams wanted pages of paper, not strips.

When the FCC finally released rules permitting FSK on the low bands, they were already out of date and extremely inhibiting to experimenters. A goodly percentage of the RTTY crowd was experimentally minded, more interested in technical developments than in rag chewing. The rules stipulated 850 Hz frequency shift at a time when amateurs were getting ready to change from this age-old standard to much narrower shifts. New filter techniques and detectors made narrow shifts practical. Years later the FCC finally okayed narrower shifts.

The requirement for Morse Code identification of the RTTY station, which the FCC eventually admitted was not needed, irritated RTTY purists. Some retaliated with RTTY simulated Morse callsigns, others with very high speed CW, and some by ignoring the whole thing as much as possible.

It was RTTY that got me into publishing in the first place. I found myself working in a spot with a mimeo machine in 1951 ... they were rather rare at that time ... and within days the first issue of the "Amateur Radio Teletype Bulletin" was in the mail to those amateurs I



The Model 12 keyboard plugged into the big heavy table. It is dominated by the motor which drives the transmitting and receiving distributors. It was very noisy.

Punched tape drive. This is unusual in that it was built in about 1952 and had an electronic distributor instead of the usual motor driven mechanical job.

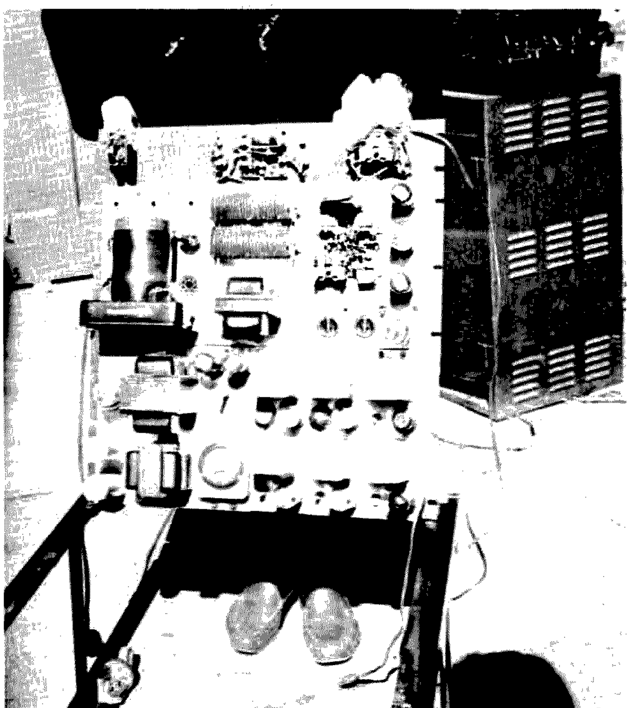
knew to be interested in the subject. I put this out monthly until I took over as editor of *CQ* magazine in January 1955.

As interest in the "Bulletin" grew, I shifted to offset printing, cramming as much as possible in the pages. By 1952 my column on RTTY started in *CQ*, and it was this that eventually led to my becoming editor. My enthusiasm for RTTY and other technical innovations has been apparent in the pages of the magazines I have edited down through the years.

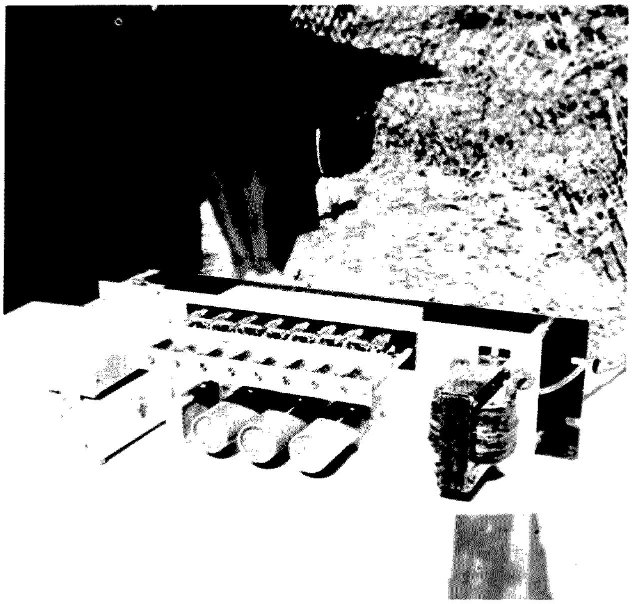
So here we are thirty years later . . . the Model 12s are long gone, Model 15s are considered too old for most use, Model 28s are popular and many amateurs are using Model 33s and 35s, which cost about as much in today's dollarettes as the Model 12 in 1946.

Even more popular now

The Model 12 was eventually replaced by the Model 15 (19) printer. Here is a photo of an operator using a Model 15 in the 73 ham shack in 1963 . . . note key for Morse ID. We've always had nice operators.



This is the converter and control panel for the Model 12. Note the filters at the lower right . . . three for the mark and three for the space tones of 2125 and 2975 Hz. Upper left is the polar relay for driving the printer magnets . . . selenium power supply for the magnets . . . autocall circuits on the upper right. This was designed and built by the grandfather of all RTTYers, John Williams W2BFD.



Back view of the electronic distributor showing plug-in tube module, power supply and AFSK tuned circuits.

are the video printing systems such as the HAL. A few amateurs are into generating RTTY or Morse via micro-computers and this seems to be the way things will be going in the foreseeable future. It costs less than a Teletype machine and is infinitely more flexible.

By the end of 1977 we should have several systems available for the lazy to buy which permit you to type out your messages, edit them as you please, with often used paragraphs or even pages available in memory for instant recall ... and the ability to make contact via FSK of any shift, make-break ... and using any popular code such as Baudot, ASCII, or Morse (at any speed ... probably up to or over 100 wpm).

It's quite possible that the RTTYers will be pioneering computer interfacing via radio, permitting exchanges of information, playing games, and a lot of things we haven't even considered as yet.

Oddly enough, RTTY, with its capacity for handling large amounts of traffic, has never been used much for this in amateur radio. Perhaps the same dichotomy which made ARRL HQ feel that they had to fight RTTY with every weapon at their disposal has been responsible. Traffic has, since the early days of amateur radio, been almost entirely an ARRL dominated function ... and the ARRL has never really come to terms with RTTY.

As far as I know, I am the only RTTY operator to ever make BPL using RTTY ... back in 1952 I set up my station on 42nd Street in New York and accepted messages for servicemen overseas at Christmastime. They were routed by two meter RTTY to DX operators and many thousands were sent to servicemen. This was all arranged by the local RTTY amateurs and the station was manned by volunteers for several weeks.

In all fairness to the League, it should be pointed out that RTTY never got to be simple enough for the uneducated amateur. It did require a pioneering spirit that few of the traffic handling amateurs possessed. And the routine involved in traffic wasn't interesting to experimenters.

This may change as more and more RTTY equipment is made available which is relatively foolproof. One can foresee the ham station of a year or two from now with auto ID, auto search receiver, auto logging ... things like that ... and all spelled out by the built-in program so it tells the operator just what to do on the CRT.

There are more than a few amateurs who are so wrapped up in the past that they do not consider RTTY or computers as legitimate parts of amateur radio. Pity ... for not only are they preventing themselves from having a lot of fun, they are pressuring other amateurs and the magazines to preserve things as they used to be instead of looking to the future.

Needless to say (hopefully), I am most interested in what you pioneers are doing with RTTY and microprocessors in the ham field. There is no question in my mind that this is one of the most important developments in the history of the hobby. Don't forget to keep notes of your work ... and write articles so the rest of us can benefit by your work ... and enjoy. ■

W2TLY, W2DXD and John Williams W2BFD.

Group of pioneer RTTYers at meeting on Long Island about 1951.

Big Noise Burglar Alarm

- - lights flashing, horns blaring

Stephen E. Uhrig WA3SWS
3893 Jumper Hill Lane
Ellicott City MD 21043

With the increase in crime rates, smart amateurs are giving serious thought to some sort of security system in their automobiles to protect their investment in communications equipment. While there have been dozens of articles published recently on alarm systems, with all sorts of fancy control circuitry, the majority of these alarms merely activate the regular car horn or a simple siren. Presented here are several other suggestions for drawing attention to your vehicle when there is an attack on the car.

A burglar alarm should fulfill two objectives. The first, hopefully, is to act as a deterrent and keep an intruder away from your property in the first place. If he wants what you have bad enough to attempt intrusion, the system should attract enough attention to make him extremely uncomfortable while he is in the progress of burgling. It is also advantageous if you get some sort of notification if you are removed from the vehicle.

The two things burglars hate are noise and light. Most alarm systems make some sort of noise, but not many people have given any thought to turning on some lights on the car when a break is detected. Many times I have heard an alarm system sounding on a vehicle in a crowded parking lot at night, but until you are standing right in front of it you cannot determine just which car is sounding off. It is a simple matter in most vehicles to activate the 4-way flashers with an alarm system and make the alarm that much more effective. As mentioned previously, the noisemaker device incorporated into the system is usually the car horn or one of the Mickey Mouse mechanical sirens. Either of these leave a lot to be desired in anything but the most elementary system. The car horn is not intended for continuous operation, and will soon overheat and burn out. A mechanical siren is not really loud or attention-getting, and can be easily disabled by the burglar by jamming the impeller with a screwdriver or ballpoint pen. In addition, these sirens are quite directional. They must be positioned near the front of the car and point out through the grille. The sound from these sirens is not the characteristic rise-fall sound of a police siren, but rather just a constant high frequency wail that in my opinion does not do the job required of it.

An excellent solution to the problems associated with the car horn is shown in Fig. 1. This circuit, engineered by K3UPU, overcomes most of the disadvantages of using the car horn that were discussed earlier. As the horns are switched on and off, the duty cycle is such that the horns will have time to cool off and can run in the alarm condition virtually forever with no adverse effects. By switching the two horns alternately, a very distinctive and effective sound is produced which is sure to draw attention to the vehicle. Most vehicles have two car horns which are driven in parallel. One side of each horn is always grounded, while 12 V dc is applied to the high side of the two horns by the horn relay when you push the horn button on the steering wheel. In K3UPU's alarm system, a standard heavy-duty flasher is used to cycle an SPDT relay. The N.O. and N.C. contacts of the relay are hooked to the high side of either horn. When 12 V dc is applied to the circuit from the alarm system control circuitry, the two horns on different frequencies are sounded alternately, producing a very penetrating foghorn-type sound. My vehicle, a 1971 Ford Torino, has only one horn installed. If this is the case with your car, a second horn can be obtained from a junkyard for a dollar and mounted in a convenient spot behind the grille.

A very excellent relay for the application is available from Tri-Tek for $1.50. These relays appeared in a recent advertisement in *73*. This circuit is good for a simple alarm when the car owner wishes to keep things uncomplicated and use equipment already available in the car.

Probably the best practical device for a mobile alarm system is an electronic siren. These can be obtained quite inexpensively, offer you much greater control, and are useful for a variety of other applications by the amateur. My favorite is the prepackaged siren/PA system designed for emergency vehicles. These are available from Federal, Motorola, or even Heathkit. I use the Heath unit in my car and am very pleased with it. The

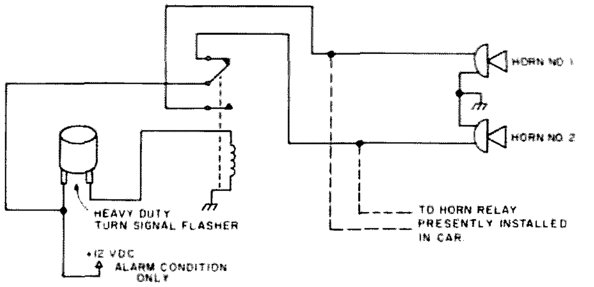


Fig. 1. K3UPU's foghorn alarm circuit.

Heath siren/PA offers both automatic and manual wail, yelp, and PA, as well as an input to the audio amplifier for a 2-way radio input. The wail takes 6 seconds to complete an up/down cycle, while the yelp takes 1/3 second for 1 cycle. To convert the Heath for use in a burglar alarm, it is necessary to have 12 V dc available when the alarm is tripped – as well as a dry contact closure. The unit draws about 7 Amps at 12 V dc for 55 Watts of audio out. This must be taken into account when selecting a relay for the system. The contact closure is necessary to select the mode of operation once an alarm has been detected and 12 V dc has been applied. I tapped in at the wafer switch on the front panel. The relay for this only needs to handle a few milliamps. 55 Watts audio output is about what a fire engine or police vehicle runs, so you can imagine the ruckus it will cause when a burglar sets it off.

Electronic sirens designed primarily for alarm use are popular in the security field and are available from most security equipment suppliers. There should be several listed in the Yellow Pages. These have the advantage of costing less than professional sirens, and are more readily adaptable to an alarm system. The audio output of these is usually only a few Watts, but is enough to do a very creditable job. These cost about the same as a cheap mechanical siren and are much better. The sirens are available either with a driver and speaker together, or separate, for special design applications.

Along the line of drawing attention to the car when an attack has been made, why not consider ways of turning on lights with the system? The leads to the 4-way flasher switch are accessible in the wiring harness that runs the length of the steering column. A contact closure will activate these. Another place to get at lighting wires is at the brake pedal switch. By putting a flasher in parallel with this switch, the brake lights will flash. Or by using K3UPU's circuit in Fig. 1, you can flash the headlights on and off, either alternately, simultaneously, or high and low beam. This will create a desirable effect. If you are serious about protecting your car, you can mount single faced trailer lights inside the back window on the rear deck. These can be wired in parallel with the bright filament of the 1157 taillight for normal brake lights and turn signals, or they can be used with the circuit in Fig. 1 and be flashed alternately. These lights also make for safer driving, as the car will be much more visible on the road. Another idea is to mount a rotating beacon inside the back window. Do not use any color other than orange without checking local regulations.

All this is great to scare the intruder away, but what if you are shopping or visiting and are some distance from the car? The alarm could sound for hours before you wandered back to hear it. Most likely it will not go too long, as I have seen police officers or residents rip out every wire in sight trying to disable the alarm. Remote notification systems are becoming more and more popular in commercial security. This should be right along the amateur's line. There are several companies that market transmitter/pager combinations designed for alarm use, but the same thing can be accomplished by an enterprising amateur for less money. A VHF Engineering transmitter board and a recycled commercial pager would make a good combination. If you use a receiver that does not have tone coded squelch, make sure to modulate the carrier somehow. I have had a receiver pick up an alarm signal which I didn't notice for some time, because the signal was full quieting. Keep the antenna inside the vehicle where it will be protected. You should still get enough range for most purposes. My system uses a TR-22C which has been modified to extend to my commercial frequency while remaining usable on 2 meters. It is modulated by an acoustically-coupled SC-628P Sonalert. This pulsating Sonalert is loud enough to fully modulate the transmitter when the microphone is on its clip on the dash and the Sonalert is under the dash. I have had some embarrassing moments when I was working an amateur channel before I left the car and the TR-22C was still on the amateur channel when the system tripped. In fact, I haven't been on the particular repeater since. I monitor the system on a commercial handie-talkie that I usually have with me. You can do all sorts of fancy things using your imagination. For a while I think I had the only mobile in existence that was connected to a central alarm monitoring station. I had a system that would bring up a repeater autopatch and dial my home, telling whoever answered that the car was being broken into. A COR monitored the repeater and stored the alarm message until the repeater had been off the air for 60 seconds. The tape mechanism for the voice signal was not reliable and the whole system was not really practical, but it was fun to play with for a while. It's important to keep the alarm down to a size that you can handle. If it gets too involved it won't be reliable – something to stay away from. Give some thought also to protecting the various components of the system from defeat. If the burglar wants what you have bad enough, as he will if you have a fancy mobile setup, he will be able to defeat *any* alarm you might have. Try to think like the burglar might. Is there a key switch he could monkey with? Can he get to the wiring from underneath the car? Slip some flexible conduit over the battery cables. Or, I went a step better. I am running a supervised alarm system in my mobile where if any part of the wiring is cut it will trip the system.

My regular car battery does NOT power the system. Even if the burglar does cut my battery wires, the system is still armed. Power for the alarm is provided by gel cells inside the car. These are recharged by the car's electrical system while I'm driving.

While the thought is in my mind, don't overlook a good loud bell for mobile applications. Bells sounding from a car are really attention-getting. Ademco makes good ones that are cheap but rugged. Again, check the Yellow Pages for alarm equipment distributors.

In closing, I'll say this: Don't put too much confidence in your alarm. Nothing will stop a determined burglar, especially if he has the time to figure it out. Be careful where you park the car and arrange for it to be checked up on occasionally if you are going to be away from it for a period of time. And again, the best security of all is having nothing worth stealing. ■

Dandy Digital Dial Decoder

-- to control whatever you want

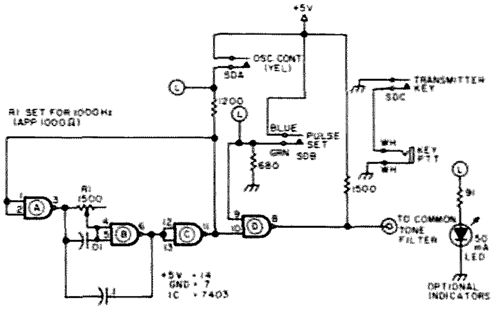

Fig. 1. Dial to tone encoder. Credit: Stamatios V. Kartalopoulos, University of Toledo, E. E. Department.

If you have a need for remote controlling anything and for whatever reason (cost, complexity, etc.) have found that touchtone signalling is not for you, then indeed this article may be the answer to your prayers. This article describes a two digit rotary dial decoder. Instead of a bundle for a touchtone dial, all you need on the sending end for this system is an easy-to-find rotary dial from the older series telephones and a single tone oscillator.

General Description of System

Following the system from the beginning with the originating station sending a tone, this tone is then broken up into pulses by the rotary dial. Whenever the dial leaves its rest position, there is one set of contacts that closes and remains closed until the dial again comes to rest. This set of contacts is wired in parallel with the user's PTT line, so the transmitter is automatically keyed while dialing. A second set of contacts that closes before the PTT set and opens after them allows the tone oscillator to run up to frequency before going out on the air. This set of contacts applies +5 V to the oscillator to turn it on.

A third set of contacts, called the pulser set, is closed during the clockwise rotation

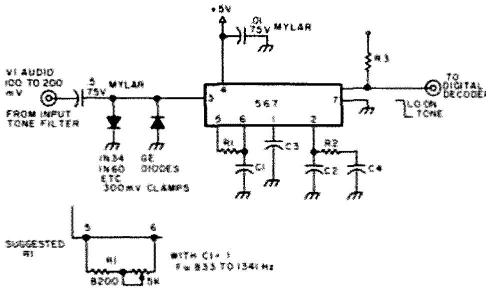

Fig. 2. C1: .1 uF. C2: 1.0 uF/6 V. C3: 2.2 uF/6 V. C4: 250 uF/6 V. R1: 6.8k to 15k. R2: 4700. R3: 2000. R2 reduces B.W. to 8% @ 100 mV in, 5% @ 50 mV in. Alternate (no R2, C4): Make C3 3.3 uF for 1000 Hz. C2 is loop low pass filter. For 1000 Hz, R1 is set at ≈ 10k. Input R = 20k. Smallest reliable V_i = 20 mV.

$$F_o = \frac{1.1}{R1C1} \qquad V_i \leqslant 200\ mV$$

$$B.W. = 1070 \sqrt{\frac{V_i}{f_o C2}} = \%\ DFf_o$$

of the dial, and then opens momentarily (like a ratchet action) at each digit position from the number you dial back to rest. There are eight openings for the digit "8," etc. This set of contacts is wired to keep the audio oscillator output from reaching the transmitter microphone audio input by any number of means (see Fig. 1).

The results are the operator sending a tone sequence of: 1. a steady tone for the duration of the clockwise rotation of the dial; 2. a number of "windows" of no tone as the dial returns to rest – equal in number to the number dialed; and then 3. a return to the transmitter unkeyed condition when the dial reaches the rest position. The decoding circuits are arranged in this "negative" logic sequence because this means a valid tone must first be received, thus leaving out incorrect tones and signals too weak to accurately trigger the system to a proper count. Only if the user is strong enough and has the proper tone will anything at all happen at the system! Also, only the addition of a second tone oscillator at the user end will double the number of system available codes. A duplicate decoder on the second tone channel at the remote site is required, but all boards are interchangeable with the first set except the tone signal decoder. This allows keeping at least one system up by using boards from the second set. If the system sees the first valid tone, it should in turn see each of the following tones and the windows between, and thus a proper count occurs.

The first decoding (for tone frequency) is done to separate the tone used for dialing and other tones used for control in our system. Therefore, the decoder appears separate from the control board as part of our

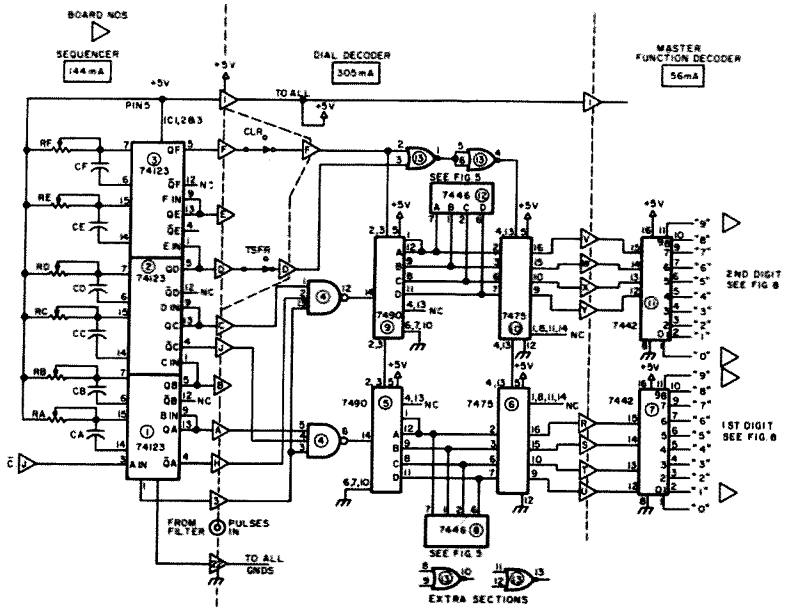

Fig. 3.

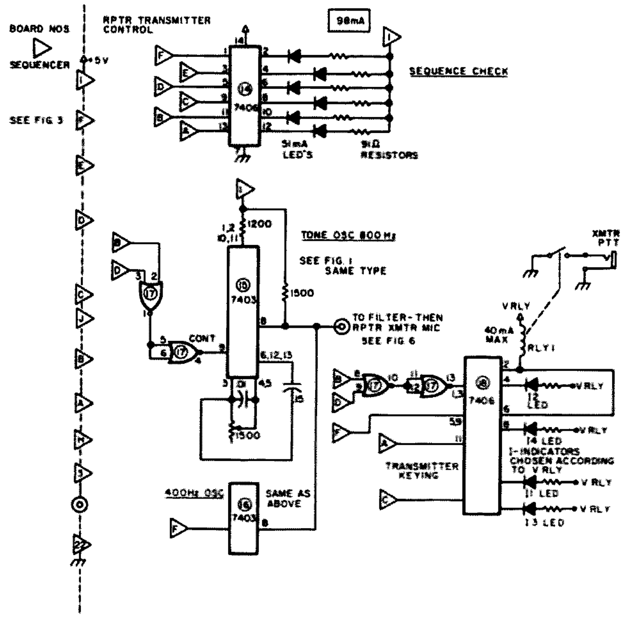

Fig. 3(a).

tone decoder board (see Fig. 2). The tone decoding is done by a rather conventional tone decoder PLL IC, a 567 type.

In our system, whenever a 1000 Hz tone is present, the decoding circuits of the 567 PLL produce a low on pin 8 of the 567 IC. This low is then carried into the control board on pin 3 (see Fig. 3).

The tone decoder changes the present or absent 1000 Hz tones into a TTL compatible level shift, from highs to lows. These pulses can then be operated on in a normal TTL manner.

The first negative going input pulse (tone received, dial moving clockwise) starts the sequencer running. The sequencer is a series of one-shot devices hooked "tail-to-head," such that the first input starts the first timing period, call it period A, and the action of its Q output going low at the end of period A then triggers the start of period B in the next one-shot, and so on through the end of period F. This makes the sequencer self-completing; thus if a user starts a dial command and only dials one number, the decoders decode the sequence as a 10 - 20 - 30, etc., command zero understood. We use this to advantage as all-off, reset, stop, etc., for a row of commands. In the case of 10, this cancels or resets all commands 11 to 19. The sequencer goes all the way through its steps after the first valid command, regardless of the second digit dialed or not, and returns to 0 - 0. This way it is impossible to "lock up" the system by dialing one number, dialing clockwise and holding the dial at the stop, etc.

The sequencer is the master timer, and as such, controls the decoding process from the first clockwise rotation of the dial through both numbers received (see Fig. 7).

Time period B is used to

key the repeater transmitter with an 800 Hz tone at the end of the first number dialed period, period A, and to let the user know to immediately begin dialing his second number when the tone quits. The second number period is period C. Period D is used to transfer the two received numbers, at this point changed from the sequential or serial form to parallel or BCD form by the 7490s, over to the decoder 1-of-10 line device's inputs – 7442s in this case. This transfer is accomplished by the use of the 7475s called latches. These latches are such that the input lines change with the incoming BCD information as the 7490s count up to the correct number, but do not "transfer" that BCD information to the output lines until the clock lines of the 7475s go high. Without the latches, the 7442 decoders would follow the 7490s' outputs and produce false low outputs at the output pins of the 7400 or 7403 function decoders for some numbers prior to and including the number desired: in our "73" example, 00, 10, 20, 30, 40, 50, 60, 70, and 71, 72, and the desired 73. This you do not want. With the latches you have exclusive outputs, at 00 and 73, the number desired.

Period E has several not too apparent reasons for its existence. One, it serves as a settling time to allow the translated (serial to BCD) and transferred number to be decoded by the function

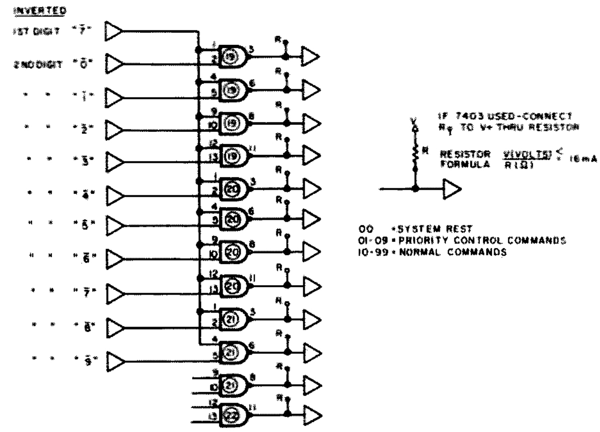

Fig. 4. (Row) function decoder boards. (70s shown.) 7403s – Note: If destination is more TTL, 7400s would be used (with no Rs).

decoders; thus the decoders remain low at the output for a finite time. This finite time is used in analog functions to allow a given amount of decoder output low time per times the number is dialed. A better explanation of how this is used is found later under the function decoders themselves. At least a third reason for period E is that it allows both clear and transfer to occur in Period F, without the clear getting involved with the dialed number transfer occurring during Period D.

Period F is a reset to 00 period by causing a high on both the clear and transfer lines at the same time, thus transferring the 00 cleared information to the function decoders. A 400 Hz tone is sent during this period back to the user, indicating the system is ready for more of the user's information. The

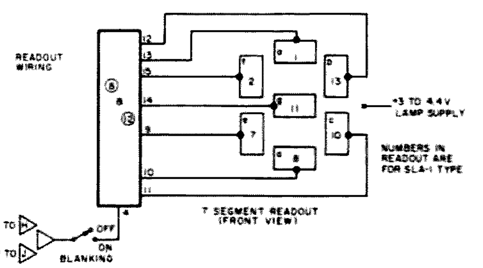

Fig. 5.

sequence is an 800 Hz tone sent to user after period A (during period B), an 800 Hz tone sent again after period C (during period D), a brief pause of period E, and a 400 Hz tone sent indicating period F – see Fig. 3(a).

With the actual decoder functions covered, a final board is left in the control group, and it is what tells the user what is happening at the repeater. The transmitter board includes an LED driver package 7406 to indicate at the repeater what state the sequencer is in.

This board also contains the two tone oscillators for 800 and 400 Hz used into the repeater transmitter to tell the user the state of the sequencer. See Fig. 7 for the exact timing sequence we have found workable.

The decoding necessary for transmitter keying is also on the transmitter board, and the same IC uses LED indicators to show whether the transmitter is keyed and whether it has 800 Hz or 400 Hz on it. The proper sequence for these LEDs is: 11 (3 sec.), 12 (200 ms.), 13 (3 sec.), 12 (200 ms.), and 14 (800 ms.).

Fig. 4 shows a typical function decoder board. One reason for building them this way is the many wires required in and out of a board versus the available connectors. Taken a row at a time like this, one line is needed for the 10s line in, ten lines for the units inputs, ten lines for the discrete ten function outputs, and one each for the +5 V and ground, or 23 lines. This is one over the 22 pin single side connectors, which isn't bad, or you can use the 44 pin connectors throughout as we did. Either way, all function decoder boards are identical and interchangeable, and you need build only eleven of them to have a full deck plus a spare to fit any one of the ten in use. The spare board is a good idea for a heavily used system. Something about fixing the system in a hurry, and then figure out what gotcha later – hi!

Fig. 5 gives the pinout on the readout decoders (BCD to 7 segment) and one possible readout arrangement. Without the readouts, troubleshooting becomes a nearly impossible task. You may want to leave the BCD from each digit as stakes or connectors, and build the decoder drivers and readouts in a separate little box as I did, thus allowing the readouts to troubleshoot other BCD type projects (i.e., DVM, counter, etc.).

Technical Breakdown

To describe a project of this complexity would require many pages on a pin-by-pin basis, so please allow me to run through the first digit, then point out only the differences for the second digit.

Sequencer – Heart and Brain of System

The 567 PLL decoder puts out a low for a 1000 Hz tone received, so as the dial goes clockwise, pins 3 of the sequencer and dial decoder boards go low. This low triggers the first one-shot on the sequencer board. Each IC section in the sequencer starts off with a high at all $\bar{Q}$

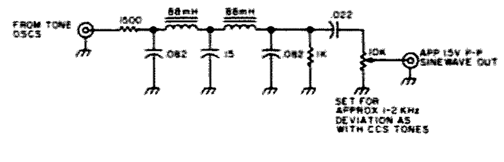

Fig. 6.

outputs and a low at the Q outputs. During each of the sequences, this reverses, such that Qa goes high and $\bar{Q}$a goes low for period A, *then* Qb goes high and $\bar{Q}$b goes low for period B, and so on. The only line then left unexplained is the IC1-3 going to $\bar{Q}$c. Pin 3 is the clear line for IC1 section A, and wiring it to $\bar{Q}$c, which is high during period A, allows the first low from the 567 to trigger section A, starting period A. When period C comes along, $\bar{Q}$c goes low and disables the retrigger feature of section A. This keeps the user's second digit from again triggering section A and starting a new sequence. Pots Ra through Rf set the exact one-shot times for sections A through F, and Ca through Cf are the Cs of the RC timing network. The Rs are all 10k thumbwheel PC mounted pots, and the Cs are chosen for the one-shot time desired. (Good starting values are: 500 to 1000 uF for Ca and Cc, 25 to 50 uF for Cb, Cd, and Ce, and 100 to 150 uF for Cf. The pots can then trim the time to the desired length.)

Dial Decoder

As the low from the 567 PLL sets the first one-shot period A, the same low is applied to IC4, pins 3 and 13. Any input line low forces these NAND gates to have a high output. Since $\bar{Q}$c is high at this time, IC4-4 is high. Qa is high so IC4-5 is high; thus only IC4-3 must return high to cause a low at the output IC4-6. This is exactly what happens during the pulse windows (no tone) of the dial returning to rest.

At this same time IC4-1 is low due to Qc being low. IC4-2 is also low due to $\bar{Q}$a being low. As such, IC4-12 output remains high regardless of the pulses on IC4-13, and the pulses only enter IC5-14 (Qc high, $\bar{Q}$a high, Qa low, $\bar{Q}$c low reverses this for the second digit during period C and one difference of the two digits is now pointed out).

The clear line of IC5, pins 2-3, is low during periods A through E, and therefore IC5 and IC9 are free to count during any of these periods (periods A and C being the ones that matter). If the readout blanking switch is turned to off, you will see each of these counts as changing BCD information (and thus readout numbers) during the dial returns.

After the period A loading of IC5 and the period C loading of IC9, period D occurs. A high on Qd, IC2-5, goes to IC13-3, a NOR gate. When either IC13-2 or IC13-3 goes high, IC13-1 goes low. A second section of IC13 is wired as an inverter to cause a high at IC13-4. This high goes to IC10 pins 4 and 13, and IC6, pins 4 and 13, the clock or transfer lines of the 7475s. Up until this clock high, the BCD output from the 7475s has been 00 or rest. Upon the clock high, the BCD outputs change directly to the loaded BCD information of their respective 7490s. In our example, the change is from 10s $\bar{Q}$a$\bar{Q}$b$\bar{Q}$c$\bar{Q}$d (0), units $\bar{Q}$a$\bar{Q}$b$\bar{Q}$c$\bar{Q}$d (0), to 10s Qa$\bar{Q}$b$\bar{Q}$c$\bar{Q}$d (7), units QaQb-$\bar{Q}$c$\bar{Q}$d (3), or direct from 00 to 73.

This BCD is sent straight on to the 7442's 1-of-10 line decoders. The 10s "7" line, IC7-9, and units "3" line, IC11-4, go low.

All ten lines of the first digit (10s) and second digit (units), from IC7 and IC11 respectively, are taken to another board in our system, though that board's contents (see Fig. 8) could be built on the decoder board with IC7 and IC11. We wanted high and low decoded outputs available, and this made 20 high, 20 low, 8 input, +5 V, and ground, or 50 lines – too many for the connectors we were using. With a second board you have 10 inputs (one low), 10 outputs (one high), per IC (10s and units), for 40 lines, plus +5 V and ground, for 42 lines. Fig. 8 should be self-explanatory in that anywhere you have an input line coming in low, it leaves high, and vice versa. For our 73 example, the first digit "7" input is low entering and high leaving, and second digit "3" input is low entering and high leaving; thus only the "7" and "3" leave the inverter board as highs.

Following these two output highs to the (Row) function decoder board for 70s row, they enter the inverted first digit "7" and second digit "3" lines, and go to one pin of all the NAND gates, and to IC19-13 respectively. Regardless of whether the 7400 or 7403 ICs are used, two highs at the input

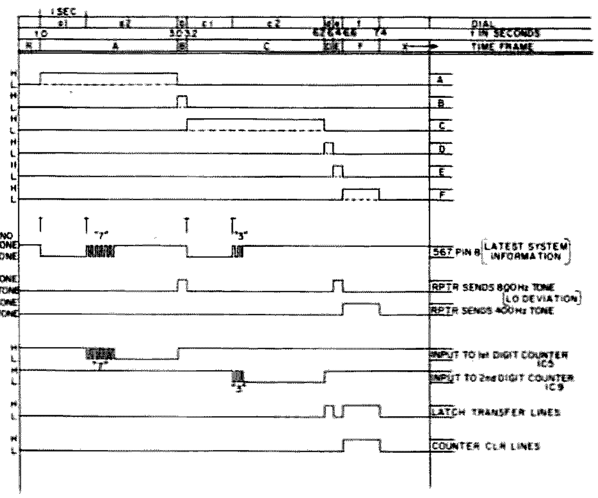

Fig. 7. Timing diagram.

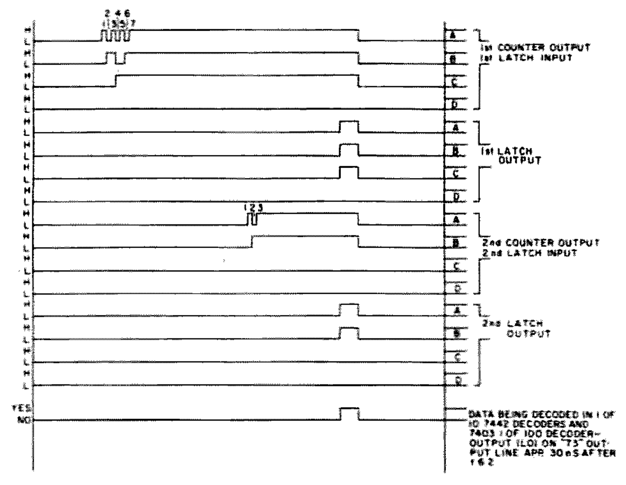

Fig. 7 (cont.).

of these gates cause a low at the output, and a low will appear at IC19-11 for a duration of slightly less than period E. You now have your 1-of-100 functions decoded.

Whether these final lows are going to drive further TTL level logic (use 7400), or drive devices such as triacs, relays, etc. (use 7403), will determine which NAND gate devices to use in the final row decoders. The 7403 has an uncommitted output device capable of sinking about 16 mA. A safer bet is to use at least a transistor buffer capable of the voltage and current you need for the relay, etc., and use the 16 mA capability lightly to just drive the transistor base. We do a little of each, so only one row decoder is shown, and it is shown less its final devices.

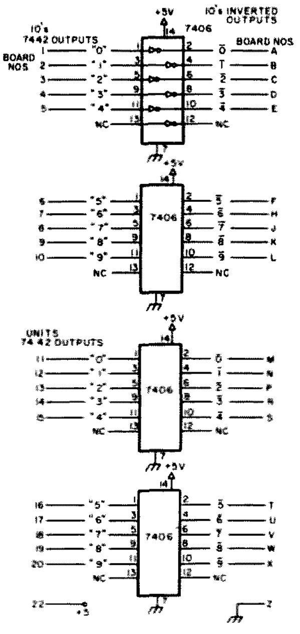

Fig. 8.

The range of devices is as varied as the things we are controlling, so none can be shown here or they would take more room than this entire article. For example's sake in the TTL device department: A 74193 and 7445 combination make up a 10 step volume control that is bi-directional. The same type pair make up a 10 step squelch control. This is our number 21-22, and 23-24 numbers for volume down-volume up, and squelch looser-squelch tighter respectively. Using a 60 series number enables a second tone decoder at a second frequency, and then 5 digit numbers can be received which represent antenna coordinates for the EME array. Example: 10165 dialed with the second tone decoder turned on by the 60 series number sent at 1000 Hz will decode as azimuth 101 degrees, elevation 65 degrees. That decoder works just like this one only there are 12 timing periods, 5-7490s, 5-7475s, and the rest from there out deleted. The BCD from the 7475s goes directly to 7485 comparator ICs that compare each number to where the beam is really at (using a coded disc on the elevation and azimuth drives), and then corrects the present location to the new dialed location in a most significant to least significant order at a different speed for each. High speed (1 rpm) for 100s, medium speed (.5 rpm) for 10s, and low speed (.1 rpm) for units, in the case of azimuth. This allows slowing down of a large mass (antennas) as it nears the desired heading.

The amount of hardware, kept mostly at the repeater site location to simplify the job for the user, has grown over five years now, and simply can't be described in a single article. Broken into several articles, I'm sure each part will find other uses — such is the way with hams. One side use at my QTH has already been found by using the teletype drive and comparator setup used for the antenna on EME coming out to a plug, so it may be plugged to more than one array. I am presently adapting it to an attic mounted 4 element yagi on 2m and crossed 6 elements on 3/4m to use mode B Oscar 7, or the 2m alone and a fixed array on 10m for A mode and Oscar 6.

Summary

That about describes how it works, and the usual SASE will get you a reply if any problems arise. I have even worked out a few ideas along other uses, such as a remote control device for devices at home while I'm away (don't care to try touchtone for *that* over the phone lines in a touchtone area!!). After I got this decoder working, I even worked out a touchtone-looking panel that sends out the dial pulses, for those of you who would rather punch than dial switch. Seriously, it makes a good push-button to serial device for other things, such as getting out just one to nine pulses whose duration (overall) you can easily vary. That's another whole article though.

There have been enough articles now to skip most of the cautions like *use a well regulated + 5 V, not 4 or 6 V.* Our decoder worked the first time with the exception of the added $\overline{Q}c$ line back to the A section input clear line — an oversight on my part from working with too many non-retriggerable one-shots.

Please advise me of your uses, and may I add at this time, if you have a project that you think could be TTL digital (controlled, run, driven, etc.), please drop me a line. This is *not* a promise to design it for you, but if it corresponds to our needs, or is simple, or we have already done it but not written it up, or it is just plain intriguing and I have the time, I'll give it a whirl. Bear in mind, since the hardware answer to your idea or question will be my design, I would retain the right to write it up — build it — use it — etc. O.K.? Let's hear from you, and 73. ■

Weather Satellite Display Control

--integrating CRT and FAX displays

In a series of previous articles in *73*, I have described two basic systems for the display of weather satellite pictures. The first of these was a multimode weather satellite monitor unit using cathode ray tube (CRT) display (August, 1975) and the second was a photographic facsimile system for readout of NOAA satellite pictures (September and October, 1975). In the concluding article on the FAX system I outlined the relative advantages and disadvantages of both display systems and ended with the remark that an active satellite station should actually have both systems available for maximum flexibility. A great many versions of both systems have been constructed, and some stations are reaching the point where they would in fact like to operate both systems. The advantages of this are many for operators who copy a great many satellite pictures. If the interfacing of the two systems is done properly, the oscilloscope which is normally required for FAX picture phasing can be eliminated. The FAX component of the system can produce quality pictures in a relatively large format — and at a low cost. The CRT monitor can be used to make negatives of particularly interesting pictures for later duplication at any size desired. The monitor can also be used for APT WEFAX copy that is not compatible with the FAX recorder. This article will

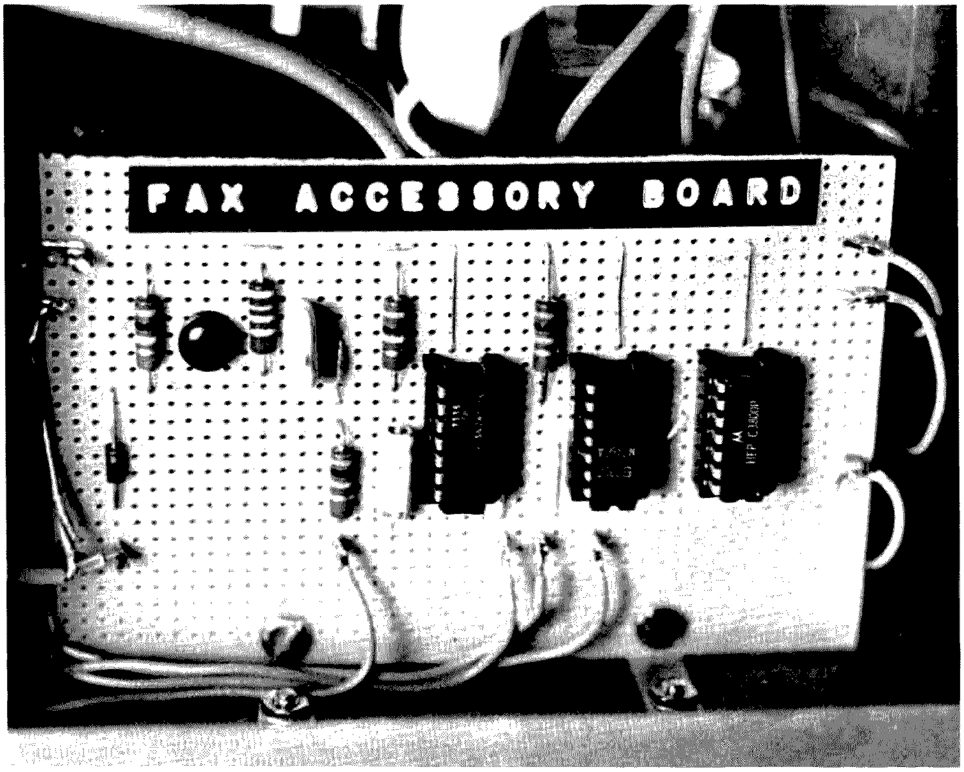

Fig. 1. Accessory FAX module installed in one of the author's multimode weather satellite monitors. A small piece of perforated board with 0.1 inch hole spacing accommodates the ICs and discrete components. Wiring the module itself takes about an hour and can be added to the monitor during or after construction.

describe a simple module that can be added to the satellite monitor to provide control of the FAX system. Pictures can be phased and adjusted on the monitor and the picture as seen on the monitor will be precisely what is printed out on the FAX recorder. The monitor can thus replace the solid state module in the FAX system, with the additional bonus that FAX printing will no longer be a "blind" operation. Simultaneous with the FAX printing, a photograph of the CRT display can be taken to provide a photographic negative for file use and later duplication in various size formats. I will also describe modifications to the FAX system that will enable you to print pictures at the 96 rpm drum rate with line blanking, thus resulting in large size pictures (averaging 5 x 7 inches for a 10 minute pass) with rolling pin sized drums. For stations who have not yet begun to construct display facilities, these modifications can be incorporated at the very beginning. If you start with the CRT system — a logical first step — FAX capability can be added at somewhat less cost than if it was a completely independent system.

If we are to tie together the operation of the CRT and FAX systems, several functions must be accomplished:

(1) The monitor must supply a phase locked 48 Hz ac signal for operation of the drum amplifier in the FAX system;

(2) Provisions must be made to trigger the monitor display from the rotation of the FAX drum;

(3) The video circuits of the monitor must drive the lamp driver circuit of the FAX system and, ideally, system levels should be such that the contrast as set on the monitor will correspond to the contrast range as printed in the FAX system;

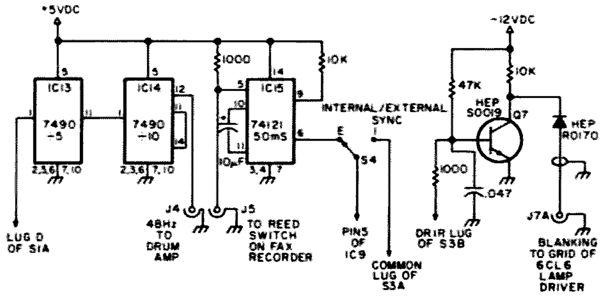

Fig. 2. Schematic of the accessory FAX module. Since the module is an addition to the basic monitor circuit, component numbers are consistent with the monitor circuit described in 73 (August, 1975). All resistors are ¼ Watt, 10% composition. Decimal value capacitors are 50-100 V mylar tubulars, while capacitors with polarity indicated are 16 V miniature electrolytics. J4-J7A are new RCA phono jacks added to the rear apron of the monitor. S4 is SPDT toggle switch added to the front panel. Power for the module is obtained from the monitor circuit.

4) The line blanking required to select either visible light or IR data in the monitor must control line blanking in the 96 rpm FAX system so the data channel displayed on the monitor corresponds to the FAX printout.

All of this sounds complicated, but in reality it can be accomplished by a small module consisting of three ICs and a single transistor. If this module, shown in Fig. 1, is added to the monitor, the monitor performs all of the functions of the original solid state module of the FAX system in addition to carrying out phasing and setting of proper video levels.

The schematic of the module is contained in Fig. 2 and, since it is essentially an "add on" to the monitor circuit, component designations follow those for the original monitor circuit. A sample of the phase locked 2400 Hz reference tone is routed to IC13 and IC14, providing a total frequency division of 50, which results in the desired 48 Hz output from IC14. This signal is routed to a new jack (J4) on the rear apron of the monitor, which is connected to the input of the FAX drum amplifier circuit.

Triggering the monitor display from the rotation of the FAX drum is accomplished by the small magnetic reed switch on the FAX recorder which closes once in every revolution of the FAX drum. This switch is connected to another new rear apron jack (J5) on the monitor. A lead from this jack to the input of IC15 in the module — a single shot multivibrator — results in a relatively long output pulse (50 ms) whenever the reed switch on the recorder closes. The long output pulse eliminates the effect of contact "bounce" in the reed switch, which might otherwise result in erratic triggering and blanking control. This pulse is routed to one lug of S4, a new switch on the monitor front panel which selects either internal triggering of the monitor display (normal) or external triggering from the FAX drum. In the external position, S4 routes the FAX trigger pulse to the horizontal trigger monostable in the satellite monitor, thus triggering the line display once every drum revolution.

Supplying processed video from the monitor to the FAX lamp driver is accomplished by connecting a shielded lead from the secondary of T1 to another rear apron jack (J6). (See Fig. 3.) Since the video level required to drive the lamp driver circuit is slightly less than that required for the monitor display, a 10k gain pot at the input of the lamp driver in place of the fixed 470k grid resistor permits the gain of the FAX unit to be adjusted so that proper FAX printing coincides with optimum display on the monitor.

FAX blanking with the 96 rpm format is accomplished by Q7 (Fig. 2) driven by the line blanking pulse from the monitor circuit. This transistor shuts off the lamp in the FAX recorder whenever a line is blanked in the monitor display; thus whatever channel (visible or IR) is

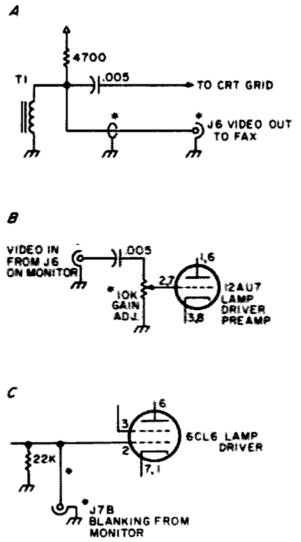

Fig. 3. (a) Video connection from the secondary of T1 in the monitor to the new video output jack on the rear apron. (b) Replacement of the fixed 470k resistor at the input of the FAX lamp driver to permit adjustment of video drive. (c) Addition of a blanking input signal (J7B) at the grid of the 6CL6 lamp driver of the FAX circuit. Asterisks (*) mark the new components.

viewed on the monitor will be printed by the FAX recorder. The signal from Q7 is routed to another new jack (J7A) on the rear apron of the monitor. J7A is connected to a new jack (J7B) on the lamp driver chassis that provides a connection to the grid of the 6CL6 lamp driver.

Drum Diameter (Inches)	Design RPM	Drive Motor Selection	Earth Scan Width (Inches)	Picture Length (10 minutes)
2.0	13.8	12/60	3.8	6
2.25	15.4	20/48	4.2	8
2.5	17.2	20/48	4.8	8
2.75	19.0	20/60	5.2	10
3.0	21.2	20/60	5.6	10
3.25	22.0	20/60	6.0	10

Fig. 4. Data for traverse motor selection based on the diameter of the FAX drum. The motor selection column assumes the use of the ¼-20 threaded rod for the traverse drive, as specified in the original article. The design rpm is the desired traverse motor speed for optimum aspect rotation at the specified drum diameter. The motor selection column represents the closest approximation of this speed that can be obtained from stock motors (Hurst DA series, either 12 or 20 rpm at 60 Hz) operated off the 60 Hz line or the 48 Hz drum amplifier supply. The earth scan width represents the width of the actual earth scan in either the visible light or IR channel, and the picture length is specified on the basis of 10 minutes of a pass using the traverse motor specified in the motor selection column. Note that for drums between 2 and 2.25 inches the image will fit — when properly phased — on a piece of 5x7 inch photographic paper. Larger drums will require 8x10 inch paper if all of the earth scan or at least 10 minutes of the pass are to be displayed.

Construction

The new module for the monitor can be constructed on a small piece of perforated board and mounted wherever convenient for the proper interconnections to the monitor circuit elements.

The connection between IC14 and J4 and IC15 and J5 can be ordinary hookup wire, as can the wiring associated with S4. The connection between the secondary of T1 and J6 and the blanking connection from Q7 to J7A should be made with shielded audio cable, as these are high impedance connections and hum introduced here would appear on the monitor display or FAX printout.

Replace the fixed 470k resistor at the input to the 12AU7 in the lamp driver circuit with a 10k pot. Add a new jack (J7B) on the lamp driver chassis near the 6CL6 and connect this jack to the grid pin of the tube socket as shown in Fig. 3(c). As long as the distance between the jack and the grid pin is no longer than 1-2 inches, ordinary hookup wire may be used. If your chassis layout requires a longer run, use a shielded cable. Label the new jacks as follows: J4 — 48 Hz; J5 — Drum switch; J6 — Video output; J7A and B — Blanking. Shielded audio cables should be used for all connections between the monitor and the various elements of the FAX system.

The major element in the construction of the integrated system is the conversion of the FAX recorder to a 96 rpm format. There are two ways to accomplish this if the recorder has already been constructed for the 48 rpm format. The cheapest alternative, provided you have access to gears, is to install a 1:2 gear system between the traverse motor and the threaded rod and between the drum motor and drum shaft. This will up the drum speed from 48 to 96 rpm and will achieve the required doubling of the traverse rate which is required to preserve the proper aspect ratio at the new drum speed. If you are the mechanical type this is probably the easiest solution, but, if you are like me and abhor mechanical devices, the simplest alternative is to purchase a set of new motors. A Hurst series CA motor rated at 120 rpm at 60 Hz will provide the proper 96 rpm speed when run at 48 Hz. This motor will mount with no fuss on the mounting plate for the original 60 rpm drum motor. As in the original 48 rpm version, the selection of the proper traverse motor is dependent upon the diameter of the drum, if we are to achieve something close to the proper aspect ratio. The original article on the FAX system provided tables for selection of a traverse drive motor based on 48 rpm operation of the drum. Fig. 4 provides the same data for 96 rpm operation. The new motors are drop-in replacements for the types originally specified for 48 rpm service, and no modification of the traverse motor mounting system should be required. You can save some money and frustration caused by back orders if the motors are ordered directly from the Hurst factory. They welcome small orders and will ship immediately from stock even on phone orders. Contact the Hurst Manufacturing Corp., Princeton IN 47670, or call 812-385-2564. They are nice people and it is kind of amazing to run into an outfit that acts as if it wants your business!

Setup and Operation

Obviously if you already have the FAX system going as originally described, your major task will be to build the monitor and get it going. The August, 1975, article in *73* will be your guide here — simply add the module to the circuit during construction. Follow the article for checkout procedures, being careful to keep the new S4 (internal/external triggering) in the internal position for all monitor setup adjustments. Modifying the recorder to 96 rpm is the next task, followed by interconnection of the monitor and FAX systems. Note that the monitor is now performing the functions of the solid state module, as well as providing a display for phasing and video gain adjustments — something that the solid state module did not accomplish. You might as well keep the original solid state module circuit elements on hand, for they are useful in the 96 rpm mode if you farm out either the FAX or monitor and have to run the FAX unit independently.

If you have the monitor on hand and are adding the FAX capability, follow the general description in the original article (except for the substitution of the 120 rpm CA series motor for the drum) and choose your traverse motor from the table in Fig. 4 of this article. You can omit the solid state module unless you wish to have it on hand for possible independent operation of the FAX unit. Proceed with the applicable instructions for checking the mechanical aspects of the FAX recorder and initial setup of the lamp driver and drum amplifier circuits. The following instructions for final setup will be slightly redundant for those stations that already have the FAX system in operation, but are provided for those who are adding FAX

capability for the first time:

(1) Turn on the monitor and set it up for normal NOAA display (the DRIR position).

(2) Apply power to the drum amplifier and lamp driver chassis, making sure that the lamp switch is off.

(3) As the circuit warms up, adjust the input level to the drum amplifier for 120 V ac across the motor windings (the drum should be clipping along if the drum motor switch is in the run position).

(4) Place a voltmeter across the drum reed switch and verify that it is closing once every revolution. If not, adjust its position in relation to the magnet on the drum until it does.

(5) With the FAX drum running, switch S4 to external, and the monitor should now be triggering from the drum.

(6) Play a satellite tape into the monitor and adjust the video gain for best contrast. Phase the picture as usual to verify that phasing operates normally when the display is triggered from the drum.

(7) With the picture being displayed in the normal manner, observe that the picture stays locked horizontally when triggered by the drum. Any tendency of the display to "wander" indicates that the drum is not holding sync. Provided that the mechanical checkout of the drum assembly indicated that the drum was not binding, carefully adjust both the drum amplifier level pot and the bias to the drum amplifier (6DQ5) to eliminate sync instability. The proper drum motor voltage will usually fall somewhere between 90 and 120 V ac. Adjusting the amplifier bias alters the 48 Hz waveform and by working both controls you optimize both waveform and voltage so that the drum will hold sync reliably. Once set, these controls will require no further adjustment.

(8) With the monitor picture showing normal contrast, turn on the lamp switch on the FAX recorder. The meter in the lamp driver circuit should bounce around in response to the video signal, and the lamp brightness should change in response as well.

(9) If you already have experience with the proper levels required for FAX printing, set the new input gain pot on the lamp driver chassis to approximate this proper swing. If in doubt as to the precise level, set it for a bit more current than normal, since you will be printing at a faster drum speed. If you have no previous experience to go by, set the input level pot so that the meter is peaking midway between zero and your black level setting.

(10) Turn off the recorder and look at the current indicator in the lamp driver circuit. It should be flipping back and forth from zero to black level, indicating the proper operation of the line blanking circuit.

If all has gone well to this point, you are ready to print a picture. If you have not already done so, mark a line on the drum to correspond to the position of the light gun when the drum magnet is opposite the reed switch. This line will serve to locate the edge of the paper when it is attached to the drum assembly.

The original article on the FAX system outlined the general requirements for photographic paper, safelights, etc. Extensive experience printing with the 96 rpm FAX system has shown that resin-coated bromide papers (such as Kodak Kodabrome RCM) are ideal. This paper can be handled under dim red safelight illumination and two safelights – one at the operating position for loading paper and watching meters and the other at the processing station – are ideal.

Under safelight illumination, mount a piece of photographic paper on the drum using doublestick tape. Position one edge of the paper parallel to the line you have marked on the drum. Fire up the monitor and FAX system and set S4 to external. Play the satellite tape through the monitor and phase the

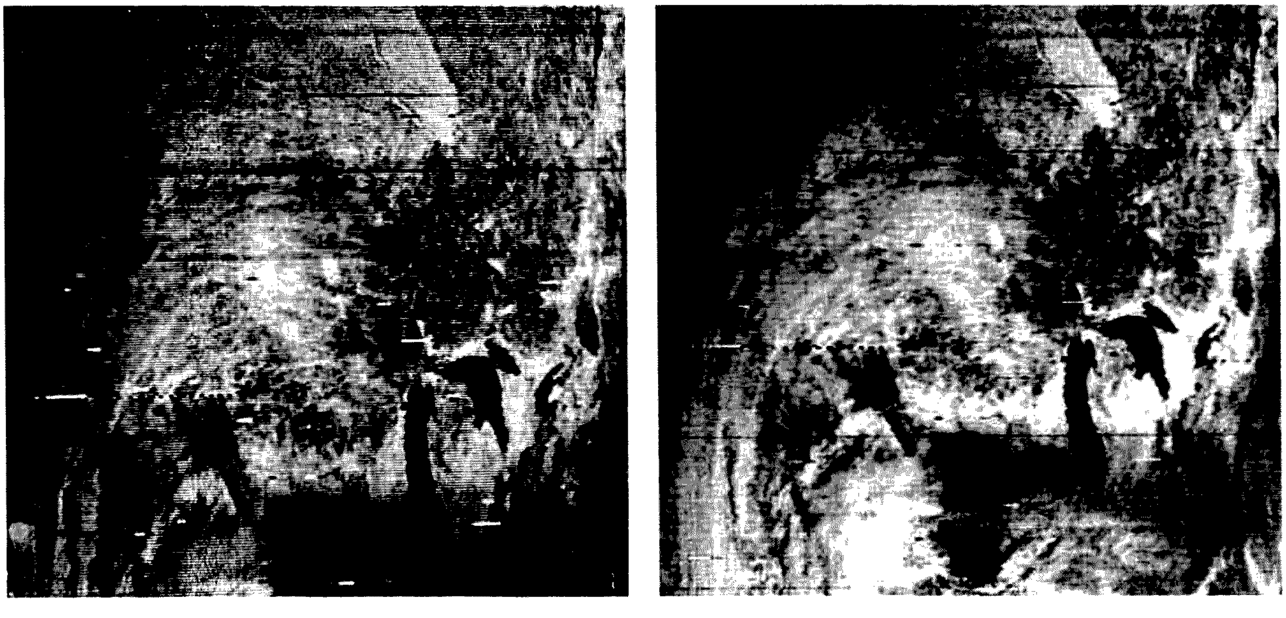

Fig. 5. Examples of simultaneous monitor and FAX readout from a NOAA 4 satellite pass across the central United States. The monitor picture is on the left and the corresponding segment of the FAX readout is on the right. The monitor, in addition to providing control of the FAX element of the system, also provides a negative that can later be printed in any size format. The FAX printout provides a high resolution picture of the entire pass, which can be used for immediate evaluation of cloud cover. The monitor also provides for picture readout in other modes that are not compatible with the NOAA FAX recorder.

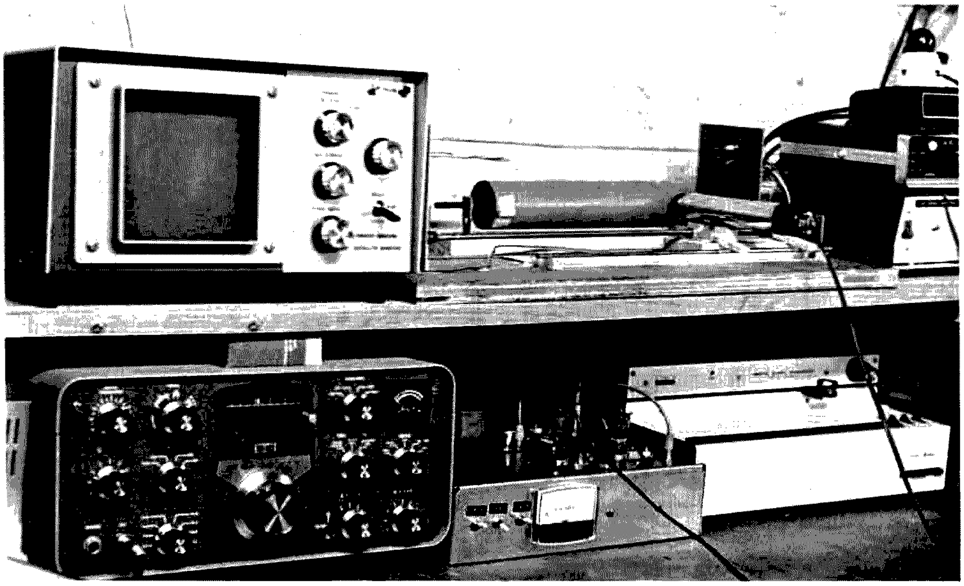

Fig. 6. The author's satellite station, where the monitor (upper right) and FAX display systems are integrated into a single display system. The actual FAX recorder is on the upper shelf to the right of the monitor. The lamp driver and drum amplifier circuits are on the chassis on the lower shelf next to the SB102. To the right of this chassis is a chart recorder (Heathkit), which records satellite signal levels during unattended station operation.

picture. Close the lamp switch in the FAX circuit and start the traverse motor. As the picture is printing on the FAX recorder, you can watch it or even photograph it from the monitor display. When the vertical scanning reaches the bottom of the monitor screen there should still be unexposed paper on the FAX drum, so simply recycle the vertical sweep and continue to watch the display until your recording is finished or until you run out of paper on the drum. Notice that any abnormality in the operation of the drum will be immediately apparent on the monitor display, which saves you the wait until the end of the recording (plus processing time) to discover that the system has glitched.

When the pass is finished, process the paper, and you should see the facsimile version of the picture you saw on the monitor. If the FAX print is too dark after normal processing, increase the gain at the input of the lamp driver. If it is too light, decrease the gain slightly. Eventually you will arrive at a setting of the gain pot where the picture on the print matches the monitor display – at which point you should resist any further urge to tinker with it!

Fig. 5 shows a comparison of simultaneous monitor and FAX display from a NOAA 4 satellite pass. Fig. 6 shows my own equipment set up for operation. Normally I use the FAX print for immediate evaluation of cloud cover, and take photos of the monitor readout to provide negatives for the file. These file negatives can be used to reproduce pictures in any size format. The monitor is also used to display APT WEFAX pictures from the ATS satellites, a mode that is not compatible with the NOAA FAX recorder.

Although having both CRT and FAX readout may sound like an extravagance, the monetary investment in the two readout devices is actually considerably less than having a monitor and camera for SSTV operation, for example. Like everything else, if you are hung up on a particular mode of operation you eventually reach the point where it is simply not enough to just operate that mode – you want flexibility and convenience as well. If you intend to occasionally read out a satellite picture, then the monitor with its multimode capability is the route to go. If you simply want to watch NOAA satellite readout and have a scope available for phasing, then the simple FAX system will do. As noted in the original article, a 48 rpm system can even be operated without phasing! The best FAX option of all is the 96 rpm format and, even if you do not intend to use a monitor, this article provides the needed design data for this mode of operation. If you find yourself dedicated to weather satellite activities of all sorts, you had better file this article with the data on the monitor and FAX system – you are likely to find that you ultimately will want to go the whole route! ■

I/O EDITORIAL

THE EDITORIAL DILEMMA

A letter from Donald Peasley of Wrightwood, California is typical of perhaps a dozen letters so far received. I realize that this is a matter of importance to possibly as much as half of the *73* readers, so it is not something to be swept lightly under the table.

I held a Novice and Technician ticket in 1968 but wasn't active because of other interests taking more of my time. Last year I again became interested in amateur radio and decided the best way to become informed and renew my interest and knowledge was to subscribe to a radio magazine. I chose 73 because a ham friend recommended it over other magazines. Well, I did subscribe, but in the short year that I have received it, the magazine seems no longer interested in new radio hams, because of the type of articles. Also, the whole magazine is rapidly becoming a computer book. The number of articles on computers, etc., is overshadowing the articles touching on ham radio (Aug 76 issue: 12 computer articles, 8 radio-oriented articles). The way I see it is that the computer magazine "Byte" wasn't successful, but you still feel you have to push it on other people, so you add one more computer article each issue. Soon 73 will no longer be able to be called an amateur radio magazine, but a computer magazine. WHY? Just like a smoker forces his habit on non-smokers by blowing his fumes around, why must an editor of a magazine use his power to influence a magazine since he is hung up on this particular phase of electronics? Can't you be convinced after one computer magazine didn't make it that all aren't that hooked on computers? Please give 73 back to amateur (ham) radio subscribers and let the computer experts get their information from other sources.

I would be most surprised and pleased if the next issue of 73 I received did not have a computer section. I would rather see a section for potential ham operators and those hams not 25 years in the hobby — something a newcomer or potential ham would understand and help them to become more entranced with ham radio. Let's not scare everyone away with all your computer articles, but give the magazine back to amateur radio as it was originally intended.

Donald Peasley
Wrightwood CA

There are several points that deserve answers. Firstly, I agree with Don that there have not been enough articles of value to the newcomer in *73*. I've written some editorials asking for such articles to be written, and a few have shown up, but all too few. I'd like to see four or five good articles for Novices in each issue . . . articles on how to get higher grade licenses, how to pick a rig to use with the new rules, how to work DX, what kind of antennas to put up, what activities are available for the newcomer in the way of traffic nets, certificates, etc. I can get CBers to take a look at *73*, but if there is nothing in the magazine which will inspire them or help them get a ham ticket, both *73* and amateur radio are the losers.

Okay, now about computers. Yes, there have been a number of articles in *73* on the subject . . . most of them very much ham-oriented, but a few were just general theory to help amateurs understand the fundamentals of this new field. Since microprocessors are going to be built into more and more ham gear, I would be doing the readers a terrible disservice if I were not to publish enough articles to allow them to keep up with this fantastic development. I recognize that there is a strong temptation to bury one's head in the sand and hope that large scale integration will go away. Microprocessors are here and they are going to grow on us, no matter how wistfully we look back on the good old tube days.

It is interesting to note that despite the incredible growth of the computer hobby field, almost all of the serious microcomputer applications have been in amateur radio. Ask any ham who has attended a convention or big hamfest this last year which of the exhibit booths were the most crowded . . . and you'll learn it was the computer exhibits.

As far as *Byte* magazine goes, to the best of my knowledge it is doing okay. I note that other hobby computing magazines seem to be prospering . . . *Interface, Microtreck* is due to come out soon, *Megabyte* is rumored to be starting soon, *Kilobyte* (tentative name) is scheduled for debut this fall. To say that I have no connection with *Byte* is an understatement . . . note the article in the latest *Byte* extolling *CQ*'s virtues and trying to pretend that *73* doesn't exist. No, *Byte* was most successful . . . my estimate is that it was worth about $500,000 or so not long after I started publishing it.

There will be less computer material in *73*, but probably not for the reasons you might think. Firstly, it is darned difficult to get good fundamental articles for the magazine . . . there are too few people who know the subject well enough to write. Then, with our starting another computer hobby magazine this fall, there just won't be that much left for *73*. We'll continue to run as much ham-oriented uP material as we can, but unless there is a big change, there won't be as much as I think we should have.

Hams getting interested in uP would do well to look at the computer hobby magazines since uP and hamming are firmly entwined. The nice thing is that once you have a microcomputer, you cannot only use it to do all sorts of things with your ham station, but it will also play games, run a small business, or do almost anything else you can imagine. *Kilobyte* promises to have a lot of ham/computer articles.

One more thing, Don . . . the great bulk of the mail coming in has been very enthusiastic about the I/O section of *73*, so I don't know how much of a body of the readership you represent. Articles like that one by Don Alexander in August are a lesson to all old-timers who are afraid of ICs.

I can sympathize with anyone who finds microprocessors a bit frightening. Not only is this new subject a complex one, but the information is very difficult to get in any easy to understand form . . . which is why I've been trying to get articles . . . and why I started *Byte* last year. Heck, I still can't understand many of the uP ads. How these firms are able to sell anything at all is a mystery to me. I've read and talked enough about computers now so I understand the fundamentals . . . RAMs, ROMs, CPUs and such . . . I've even put a computer system together and got it working . . . still I'm lost when it comes to trying to figure out what some manufacturers are actually selling, what it will do and what else I need with it or will work with it.

To sum up . . . we do need articles for ham beginners . . . and we need material for computer/ham beginners. How about it?

10,000 MILES

A year ago I made a trip to visit the manufacturers of hobby computers and reported in *73* on my findings. At that time there were three . . . MITS, Sphere and Southwest Technical Products.

The field has grown a bit during the last year and it seemed like a good idea to update my visit exactly one year later . . . this time with a visit to MITS, Sphere, Southwest Tech . . . plus Jolt, Imsai, Apple, M&R, Godbout, Morrow, Wave Mate, and Intelligent Systems. It was a most interesting trip.

The manufacturers of hobby computers come in all sizes, from great big plants down to a corner of a garage. My reception ranged from the most formal of interviews and a refusal to let me take pictures at Imsai to a flight up to Santa Rosa for dinner by Godbout and an all-day rag chew with Ed Roberts of MITS, complete with some looks at his most tightly guarded developments.

The increasing number of ham applications for computers had gotten to Ed Roberts, and he was hard at work to get his ham ticket . . . look for him soon on 20m doing some DXing and undoubtedly in there with RTTY, computer assisted. Not a few of the computer hobbyists are getting into hamming these days.

One of the newest of computer firms is Apple. This is run by two youngsters (maybe 20?) out of one end of a garage in Los Altos. Despite the humble facilities, the system they've created is worthy of serious consideration and I'll be covering it in some depth in *Kilobyte Magazine*. Their main efforts, at the time of my visit, were on the development of programs for the system. This was about the same for almost all of the firms I visited.

CB activity in the Western reaches is much less than I expected. And though I had two meters with me too . . . and made a lot of fine contacts . . . I found CB invaluable for finding my way around strange places and avoiding traffic problems.

Jolt has a very interesting computer setup . . . a most interesting design . . . and I suspect that it is only a lack of general knowledge about it that has kept their sales down. I really can't put them down for that, since I honestly can't point at any manufacturer in the whole industry who has literature which is aimed at what I see as the main market for this equipment . . . the beginner. I wouldn't be surprised if the first firm to come out with really easy to understand literature might not find themselves in a runaway situation, trying to keep up with the flood of orders. There are an awful lot of people out there who think they want a computer, but who are unable to figure out what system they need . . . or how much it will cost. And a lot of people get mulish when faced with signing a blank check.

You'll be seeing a lot more about the Astral 2000 system . . . M&R . . .

by John Craig

I/O REPORT

I/O HELP

Received an interesting letter from Kenyon Karl in which he suggested we start an I/O Help column in the I/O section to complement the Ham Help column. He would like to get the ball rolling with this entry: "I can help with the writing and debugging of BASIC programs for your microprocessor system. I write COBOL programs (another high-level language . . . but for larger machines) for a living." – Kenyon F. Karl, 36 Prospect Street, Waterville ME 04901.

THE HOMEBREW COMPUTER CLUB

I recently made a run up to the San Francisco area to check on the Homebrew Computer Club. Not only are they a dedicated bunch (they meet twice a month) but they also have some of the sharpest talent in the country (which stands to reason since they're right in the heart of the "Silicon Valley"). The meetings are held at the Stanford Linear Accelerator Center. Stanford has a "no selling" policy, so there were about half a dozen systems set up for demonstration only (which precludes the flea market seen at most other club meetings). The iron hand of Lee Felsenstein (designer of the Pennywhistle Modem and other goodies) conducts the meetings . . . and with over 300 people in a room it helps to have someone keep things under control! One of the most interesting aspects of the meeting came when adjournment was announced. About two hundred fanatics rushed the podium to get first grabs at the stacks of pamphlets, data sheets, product descriptions, and flyers which were placed on the stage. (For an anxious moment I thought Felsenstein was about to meet his Maker!)

Marty Spergel of M & R Enterprises gave me a tour of his new baby, the Astral 2000. The Astral is a 6800-based system which has some really fantastic hardware features and powerful software to make it more than "just another computer coming on the scene." We should be getting one of these units for evaluation in the near future, so keep your eyes open for the write-up . . . it should be a corker!

Another system which has a high interest level among hobbyists is the PACER, built around National Semiconductor's PACE. Project Support Engineering of Sunnyvale, California, had their PACER doing its thing at the Homebrew meeting. I expressed an interest in doing an evaluation of the unit and they responded by sending me one within two weeks. It's sitting across the room waiting for me. We'll have a New Products write-up on it soon and give you some thoughts on the processing power of a 16-bit machine (versus the 8 bits we're used to).

RAP SESSIONS

While up in San Francisco I also had the opportunity to sit down and do some elbow-bending and jawboning with Jim Warren (of *Dr. Dobb's Journal*) and Bob Reiling (Homebrew newsletter editor). I also had a visit for an entire afternoon from Sheila Clark and Art Childs (editor and ex-editor of *Interface*, respectively). One of the common denominators of these conversations was the common agreement that the direction of home computer systems will be towards entertainment and education applications, with very little emphasis on exotic control applications (turning on the sprinklers, monitoring the environment, security systems, etc.) that we've heard so much about. The amount of hardware (and hardware expertise) to implement a 24-hour monitoring system would be considerable. Then, of course, the amount of electricity such an application would require would be something to consider. If these control applications are going to be handled by a computer they will have to be accomplished using a dedicated microprocessor-based controller.

FURTHER REFLECTIONS ON SMALL BUSINESS SYSTEMS

In last month's I/O Report, I mentioned the possibility of putting together a "dumb" key-to-tape data entry terminal which could be used for storing data and transactions on a cassette. The cassette would then be picked up (each evening) for processing at a central computer (the one in your home). Another important capability a small business would require would be the ability to retrieve data during the day (e.g., if a customer calls up and asks what his balance is, the secretary should be able to walk over to the terminal and get the information . . . rather than having to look it up in the files). Therefore, it's beginning to look more and more as though a "smart" terminal (one which contains a microprocessor) will be the answer for an application such as the one I've described.

I'm presently putting together a talk for a seminar at the Personal Computing '76 convention in Atlantic City. The seminar will be entitled, "The Outlook For Low Cost Small Business Systems," and it looks as though I'll have to emphasize what the future holds for small business systems, rather than what the present has to offer. It seems that there are several people working on the development of these systems around the country, but everyone is in the same boat . . . he has the hardware but the software is still a gleam in his eyes. There's an awful lot of it to be developed. The whole thing needs to be developed around a "people-oriented" executive program which will accept commands from the operator and run the other programs which make up the system. These other programs would include inventory control, accounts receivable, payroll, customer mailing lists, and text editing for generation of letters, just to name a few.

It occurs to me that the possibility exists for development of this software by several groups or individuals scattered across the country. If modular programming techniques were employed, and the developers were to agree upon the structure and commands of that executive program, it would seem that the individual programs could be integrated into a whole system. The only reason I even bring up such an idea is to help reduce the cost of software development – and thereby sell systems that cost less. (If I were a programmer and had just finished a year and a half developing all of those programs mentioned above, I certainly wouldn't want that software sold for anything less than a large chunk of money.) I'm fully aware of the fact that such an undertaking would require a certain amount of coordination and leadership from the person (or persons) "in charge" of the effort. If that person (whoever he is) wrote an article detailing the plan, he could probably get enough of a response from interested programmers to turn the thing into a reality.

CORRECTIONS AND ADDITIONS

Dick Whipple and John Arnold have discovered a couple of minor corrections to be brought to your attention regarding their "Baudot Monitor/Editor System" in the August issue: 1) In the fifth paragraph from the end, the output routine address should have been 001215 instead of 001205 (the address of the output routine shown in Table 4 is correct). 2) Location 000104 should be changed from 215 to 320 octal (as it was, a "?" would be printed in the wrong case when an unknown command was entered).

Dick reports that he is getting a steady stream of orders and inquiries concerning the BM/E article. Several people have called long distance to talk with him about it, and it appears interest among hams is beginning to pick up. His next article, on the amateur version of Tiny BASIC Extended, will be coming up in the near future.

We've received several comments on the fact that the listings for the PROM were not included in the article on "A Morse to RTTY Converter" by WB6SQU in the June issue. We have a policy here at *73* to make every attempt to insure that construction articles are complete. Therefore, you'll find a copy of those listings in this column. Stanley Levy WB6SQU was kind enough to make them available, but he also pointed out that a number of people have purchased the listings (as per the article) for $3.50. If you're a member of this group, *73* will be happy to give you a *$4.00* credit toward the purchase of any *73* publications, cassettes, or subscriptions (just send us a receipt or copy of your cancelled check). Incidentally, the new address of Levy Associates is PO Box 514, Monrovia CA 91016.

ON-LINE

Many moons ago when I was involved with the *Micro-Eight Newsletter*, I did a short write-up on a newsletter just coming on the scene called *On-Line*. With the passage of time, it turned out to be one of those things which fall by the wayside, and I never got a subscription. The other day I received a complimentary issue and now see what I've been missing. It's neat!

Each issue of *On-Line* contains 6 to 12 pages of classified advertisements devoted entirely to the computer hobbyist. It looks like a pretty good way to pick up or sell used gear. And a dollar for four issues is quite reasonable. Contact D. H. Beetle, Publisher, 24695 Santa Cruz Hwy., Los Gatos CA 95030, if you're interested.

MORSE CODE-TO-BAUDOT PROM LISTINGS

Following are listings for the PROM mentioned in "A Morse to RTTY Converter" (June, *73*). Stan Levy WB6SQU pointed out that the listed addresses are "system addresses" (i.e., used during development) and correspond to locations 000 through 1FF in the PROM. The addresses within the program do not need to be changed, since the PROM is addressed by only the nine least significant

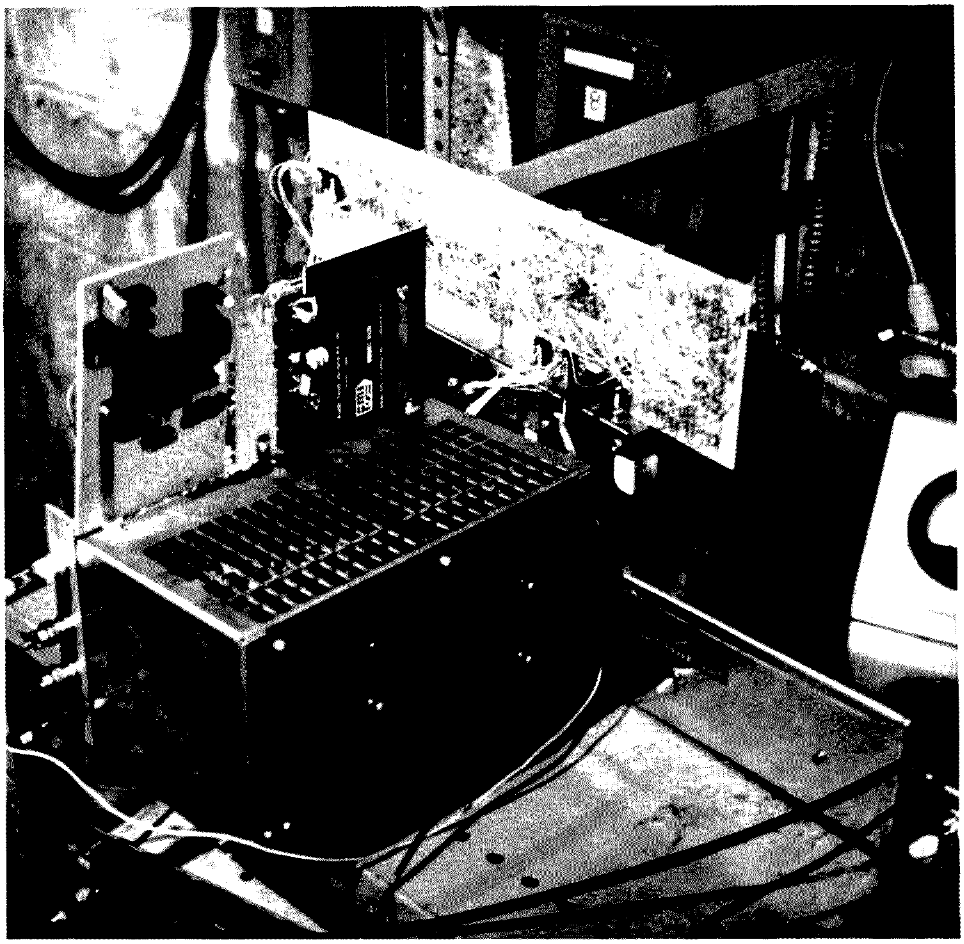
Ham Time-Sharing is Here for You!

-- via a repeater

Bruce J. Brown WB4YTU/WA9GVK
4801 Kenmore Avenue #1022
Alexandria VA 22304



Microprocessor, demodulator, A-D converter, and character generator — the ingredients of RTACS at the WR4AAG ATV repeater.

Numerous magazine articles and symposium speakers have extolled the possible virtues of microprocessors in amateur radio applications. This plethora of prognostication, while generating considerable interest, has created a great deal of skepticism as well. After all, amateurs, being pragmatic by

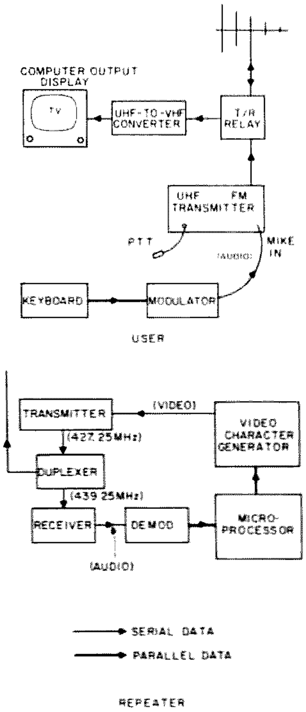


Fig. 1. Remote Terminal Access Computer System.

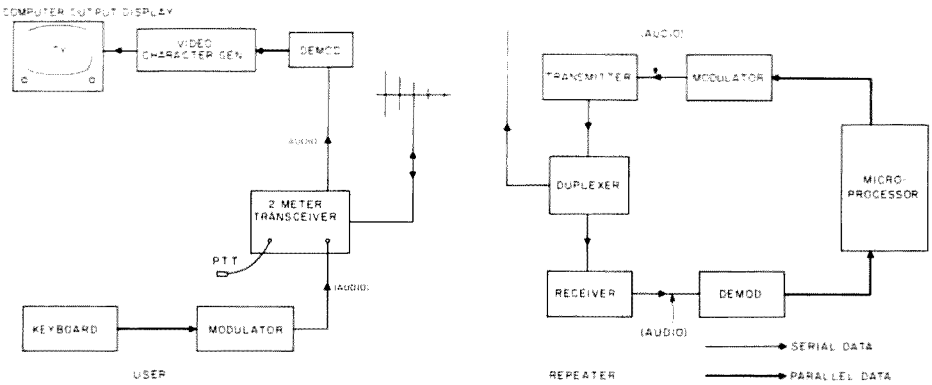

Fig. 2. Possible remote terminal system for voice-only repeaters.

nature, are more concerned with the realities of the present than the possibilities of the future. Few hams relish the thought of spending $1000 on a computer system which might ultimately serve, at best, as a light-blinking toy rather than as the useful station addition originally intended.

The purpose of this article is to affirm the present value of microprocessors in amateur radio, while demonstrating that their benefits can be reaped without undue individual expense. This will be shown by describing a unique computer-based system which has been operating successfully for well over a year in the Washington, D.C., area.

In early 1974, members of the Metrovision Amateur Television Club, sponsors of the first fast scan TV repeater (WR4AAG), recognized the potential power of recently introduced microprocessor chips and set out to design a far-reaching computer system to enhance amateur station performance both technically and operationally. The concept was to give numerous local hams computer capability at their own shacks through the use of a single, shared, centrally-located processor. Thus each station would be spared the expense of building or buying a separate computer. Furthermore, it was envisaged that the remote nature of the system could provide capabilities that even the most complex home-based computer could not render.

What is this super-system? It's called a Remote Terminal Access Computer System (RTACS), and is used as an integral part of a repeater.

Writing and executing computer programs from the comfort of your shack is just one basic capability. The system will also measure your signal strength into the repeater, power output from the repeater, automatically call CQ for you, store and forward messages to other amateurs, and serve as an information retrieval library. Let's take a look at the system configuration.

RTACS – General Background

The system is similar to commercial time-share computer networks using terminals at a location remote from the processor. You may already have some experience with remote terminals at work or school. Fig. 1 shows the amateur radio implementation of this approach, using a TV repeater.

At the home QTH, the user requires only a keyboard and modulator to convert the parallel keyboard data into a serial, tone-modulated signal which is applied to the microphone input of an existing transmitter.

The signal is sent up to the repeater, where it is received, converted back to parallel data and fed into a microcomputer. At the WR4AAG repeater, a home brew 8008-based processor is employed with 2K RAM and 2K PROM. The output of the computer is fed into a character generator, which formats the data into a standard 525 line video signal that is transmitted back to the user and displayed on a home TV set through a UHF-to-VHF converter modified for ATV (amateur television) reception.

It is thus possible for a ham to have computer capability in the home without the hassle of constructing or buying a processor and video display device – an investment easily amounting to several months of effort at a $1000 price tag. With RTACS it is possible to write programs, list data out of memory, and execute programs. It is invaluable as a learning aid for machine/assembly language programming, as well as for performing a myriad of beneficial tasks in direct support of amateur radio operations.

So as not to give the impression that RTACS is the greatest thing since the invention of the carbon resistor, it is fair to point out some inherent drawbacks. First, only one user at a time is possible. Common on-the-air courtesy dictates who uses it and for how long. Secondly, there is no security to your data. Everyone can see your inputs and outputs (if that's any concern to you). Finally, the system, as presently configured, precludes its use for direct control or switching applications around the home, as would be possible with a locally based device. Nevertheless, the simplicity and cost benefits outweigh the disadvantages in most instances.

When operating a computer remotely, some provision must be incorporated to allow the terminal user to restart the processor in the

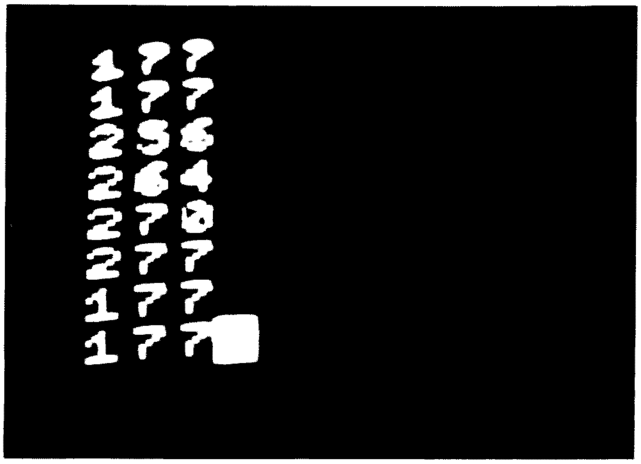

Fig. 3. Signal strength samples at 2 second intervals. No signal reads 177. Display shows transmitter turn-on, gradual increase in signal, followed by turn-off.

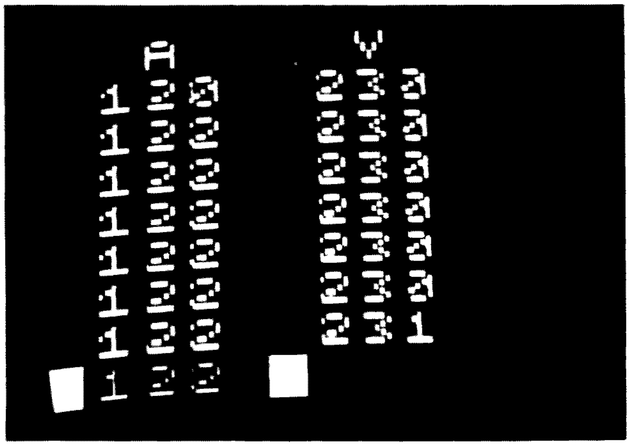

Fig. 4. Audio and video transmitter power levels in left and right columns, respectively. Samples at 2 second intervals. A separate calibration table is used to convert these numbers directly into Watts; e.g., 122 corresponds to 10 Watts, and 230 equals 80 Watts.

event of a software problem such as a loop or a halt. At the WR4AAG repeater, a hardware circuit monitors the output of the demodulator to sense a specific control character. Upon its detection, the circuit sends a 005 interrupt command to the 8008 processor, to override any other instruction that may be executing.

While the video output capability of the ATV repeater does conveniently lend itself to the RTACS, a standard voice-only repeater can be used. Fig. 2 shows one possible method for doing this. At the user station, a keyboard and modulator are also used. At the repeater, the character generator is replaced by a modulator to convert the parallel output data from the computer into serialized tones. On the receive side, the user would have a demodulator to convert the tones to parallel data for driving a local character generator. Thus, from the home QTH side, an additional \$150 investment for a demodulator and character generator is required, as compared to the ATV repeater configuration. Another difference would be in the computer's control program which must prevent computer output from being transmitted until the user drops his/her carrier to enable reception of the data. This would not be required if the user can operate full duplex.

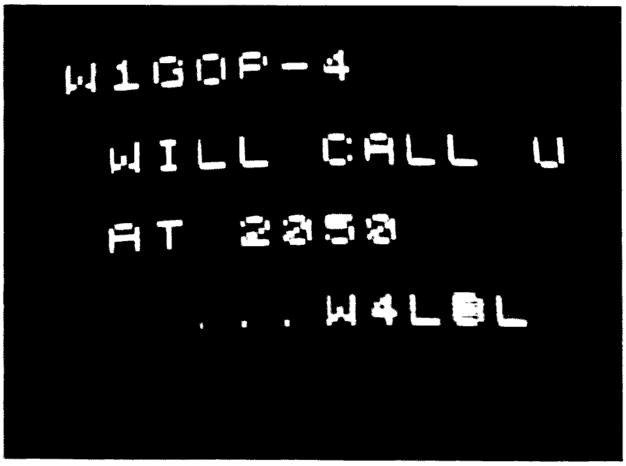

Fig. 5. Messages may be stored in the computer and later recalled by the intended recipient.

Some specific applications of the system used at the WR4AAG repeater will now be examined.

Remote Signal Strength Measuring Program

Ever wonder how strong your signal is compared to others? Would you like to measure antenna performance even though you don't own a field strength meter? Want to know if your transmitter is tuned up for greatest output power but don't have a wattmeter? Are you interested in knowing how day-to-day propagation changes affect your signal?

Amazingly, without any test equipment, you can determine all of the above with the RTACS. To call up this special program, you turn on your modulator and type the letters S-I-G-N-A-L on the keyboard.

While monitoring the output of the repeater, a 3 digit number will be seen on the left side of the TV screen. This number is directly proportional to your signal strength as sensed by the repeater's receiver. If you increase transmitter power, the number will increase in value; if you change to a lower gain antenna, the number will drop. Thus you get an objective figure of merit for your signal strength. No more inaccurate RS reports!

How does it work? An analog-to-digital converter is connected to the repeater TV receiver's AGC line. The A-D converter's digital output is fed into the microprocessor which, in turn, is connected to a video character generator tied to the repeater transmitter. Thus, a number is generated and displayed in a TV format which is directly proportional to received signal level. (A sample of this printout is shown in Fig. 3.)

Typical applications of the system are:

1. Accurate transmitter tune-up
2. Comparing transmitters
3. Measuring performance of transmission lines
4. Comparing antennas
5. Examining antenna pattern (sidelobe, F/B ratio, etc.)
6. Proper antenna positioning (azimuth, elevation, polarization)

Power Meter

Many times the question arises, "Is my receiver bad or is the power output of the repeater low?" Thanks to the microprocessor, the answer can quickly be found. By calling up the POWER program on the keyboard, the power output levels of the repeater's video and audio transmitters are given. The numbers that appear on the screen, while not in Watts, do directly correspond to a specific power level that can be determined by referring to a calibration table. (See Fig. 4.)

How does the system work? The detected rf output from the aural and video transmitters, derived from directional couplers with diode detectors, is fed into an A-to-D converter and on into an input port of the microprocessor. The microcomputer then formats the data into columns which are appropriately labeled.

Message Store and Forward

In this mode the user is able to remotely control the character generator at the repeater to place any desired message on the TV screen. The message may be in the form of a club bulletin or possibly be directed to a single individual. It is especially useful for leaving a message for a fellow amateur who is not home but can later turn on the TV and retrieve messages addressed to him. Several variations of this capability are provided to the

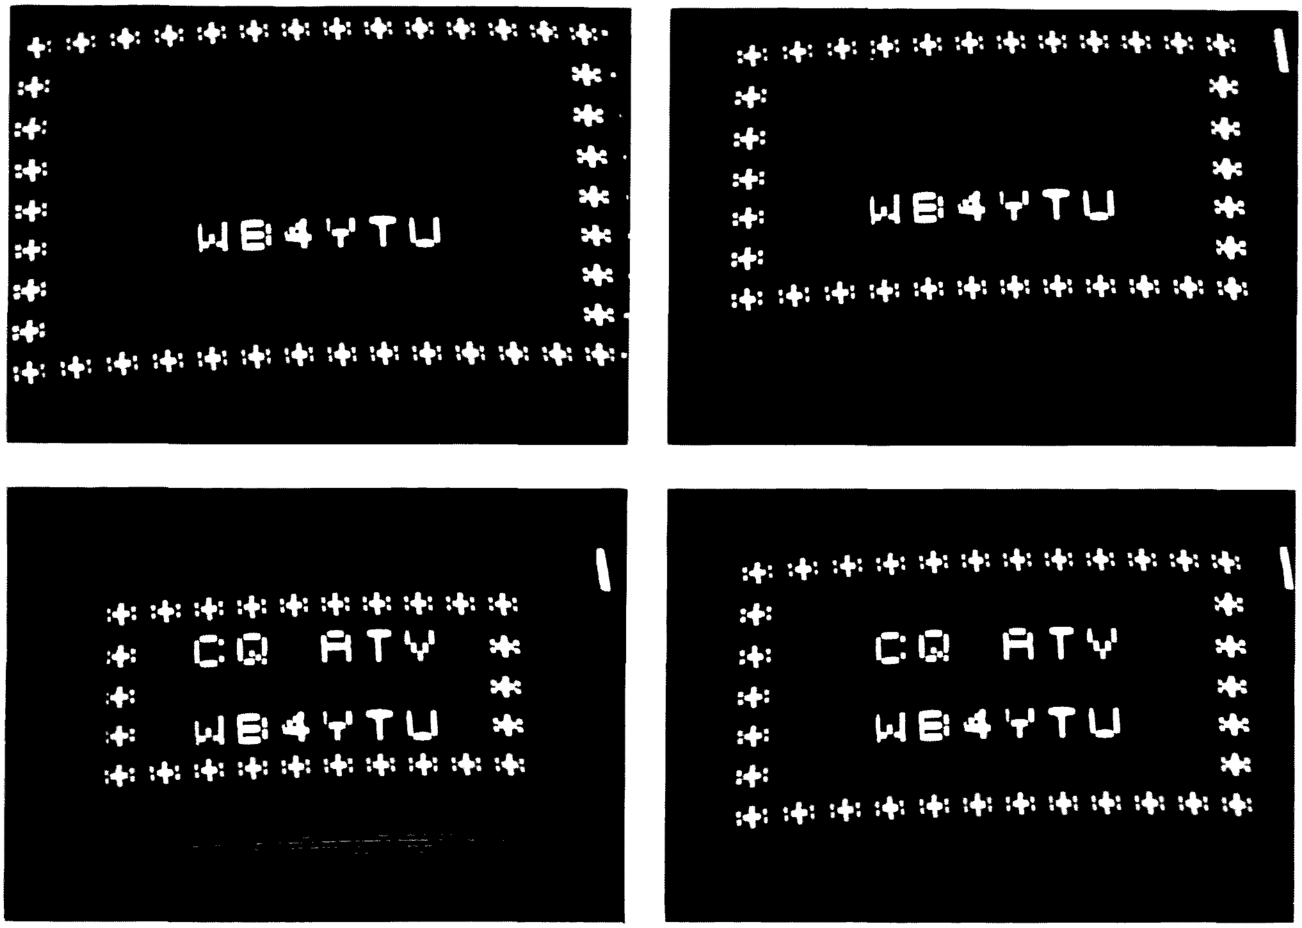

Fig. 6. Computer generates four "pages" of data in the character generator's buffer memory and then turns each page every 0.2 seconds for animation. In the display shown, "CQ ATV" will flash and the outside border will appear to expand and contract.

user. Fig. 5 illustrates a sample printout. Messages can be transistory (stored only in the buffer of the character generator) or can be made more permanent by storage in the computer's random access memory (RAM).

Automatic CQer

By typing the CQer command followed by your call letters, the microprocessor will generate an animated video CQ display. It does this by loading 4 pages of the character generator buffer memory and then turning the pages at high speed to create animation. The photos in Fig. 6 illustrate how this technique serves as a real "attention getter."

Data Retrieval

Several applications are possible involving the storage and selected recall of data. Call letters, addresses and dates can be entered into the computer's memory to serve as a paperless logbook. Once the information has been entered, a keyword can then be typed to retrieve desired information. For example, on the WR4AAG system, by typing call letters on the keyboard, the computer will tell you the person's handle, address and telephone number within 1 second — considerably faster than trying to look it up in a logbook or directory. Other uses include displaying pre-stored propagation or Oscar orbital information. The main limitation of all of these applications is in the size of the memory. An audio cassette tape recorder is an excellent low cost means to achieve the bulk storage of data for this purpose.

In Closing

You can now see how the microprocessor is presently employed in a practical role to assist amateur operations, and that these applications far transcend those possible using only random logic. Needless to say, *73* readers will be able to think of even more spectacular uses for the microprocessor in ham radio. ■

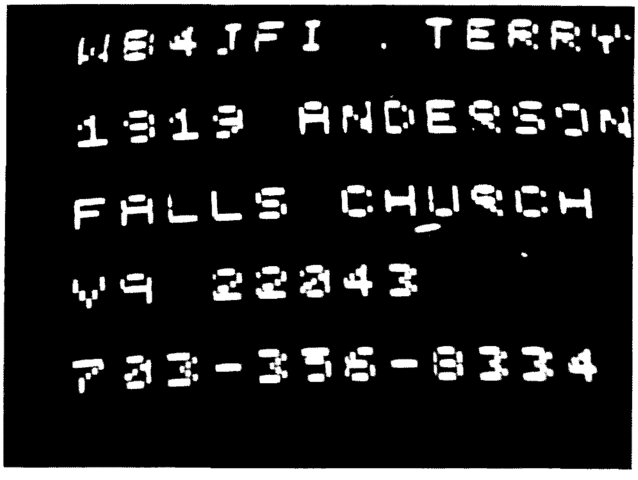

Fig. 7. After typing call letters on the keyboard, the computer will retrieve a corresponding name, address and phone number.

The Soft Art of Programming

-- part II

Rich Didday
1218 Broadway
Santa Cruz CA 95062

What next? You've probably spent a fair amount of time playing around with your home computer system by now. You've gotten familiar with the features and basic elements of your programming language. You've copied some game programs and written some small, fun programs of your own. Maybe it's time to take the big plunge and try something "real," something you couldn't do just as well on a pocket calculator or by counting on your fingers.

In this article (and in the concluding part next month) I'm going to take you through the thought processes involved in defining, designing, refining, and coding a program which allows the user to store and manipulate a large file of information – a "data bank" of sorts. The goal is much more than just laying a program listing in front of you and saying, "Here it is, here's how to use it, copy it if you want." I hope to give you a feeling for *doing* programming and the confidence to try it yourself. That means we're not just going to zip smoothly along from problem statement to finished program. No, we're going to make a plan, start following it, stumble upon unforeseen problems, revise our plan, start in again, etc., etc. Programming can be frustrating at times, but it is also really exciting. It's like any other creative activity – there's no magic way to leap to a finished product without going through a struggle. Incidentally, although our path may be a little rocky, there *are* a number of ideas and techniques we'll come across which are valuable in many cases even if some of them ultimately fail in this specific problem.

Here's the problem we'll work on: Our local computer club has been growing so fast that we're having trouble keeping track of the membership records. How can we use our computer to help us?

In designing any program, the first thing to do is calmly and carefully figure out exactly what it is we want it to do. We don't want to spend days slaving over a hot teletypewriter only to discover that our finished program is inadequate, inconvenient, or irritating for the user to interact with.

Up to now, our club has used a 3x5 index card for each member, and we've listed a number of things on each card:

1. member's name
2. mailing address
3. dues paid until ____
4. type of system ("Altair 8800," "Sphere 320," "homebrew F-8," "none," etc.)
5. wants to be on mailing list ("yes" or "no")

There are three different things we do with the records. For each new member, we make a new card and insert it. We update the information on specific cards (when a member gets a new system, pays dues, . . .). We go through the whole stack of cards and pull out certain ones to do mailings (for example, every few months we go through and pull all the cards of people who need to be reminded to cough up more dues). See Table 1.

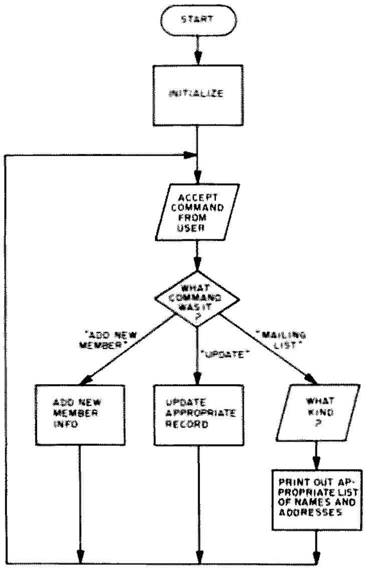

Fig. 1.

As we think about creating our program, we'll keep the different uses in mind to be sure they can all be done

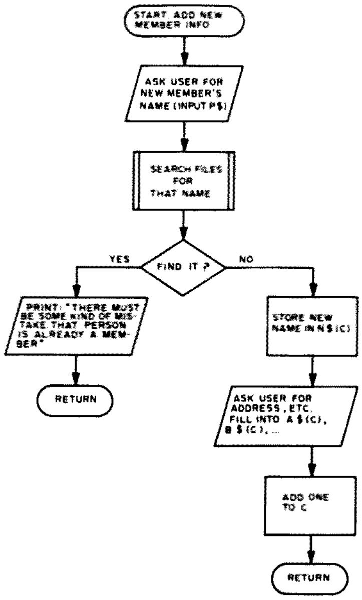

Fig. 2

conveniently. Since the way we store each member's data will affect how we access it, the first thing to do is to decide what memory organization to use. That is, we should design a *data structure*, one that is general and flexible enough for our purposes.

The simplest data structure that's made up of more than one memory word is the *array*. Arrays have been used as data structures from the very beginning of computing, and form the basis for the more elaborate organizations (stacks, lists, strings, etc.) that have evolved through the years.

An array-type organization is perfectly suited to our application because we have a large number of identically shaped items (the membership records) to store. Exactly how we use arrays to store the individual records depends to some extent on the details of the language being used.

I'll assume we have the features of Altair 8K Basic, and suggest what to do if you don't.

What we can do is declare an array for each different type of information we need to store, and associate (in our minds and in our program) the values which appear at the same location in the different arrays.

```
60  DIM N$(100),A$(100),B$(100),D$(100),S$(100),L$(100)
70  REM  N$(I) IS THE MEMBER'S NAME
80  REM  A$(I) IS THE MEMBER'S STREET ADDRESS
90  REM  B$(I) GIVES THE CITY, STATE, ZIP
100 REM  D$(I) IS THE DUES EXPIRATION DATE
110 REM  S$(I) DESCRIBES THE MEMBER'S SYSTEM
120 REM  L$(I) IS "YES" IF THE MEMBER WANTS
130 REM          ON THE MAILING LIST
```

The value for "I" will correspond to the position in the array of that particular data. To store the required information about member number 12, we could use assignment statements (LET statements) like these:

```
LET N$(12)="RAYMOND LANGSFORD"
LET A$(12)="320 FENNLY DR. #256A"
LET B$(12)="LA CERVEZA CA 92018"
LET D$(12)="JUNE,1978"
LET S$(12)="HOME BREW 8008"
LET L$(12)="NO"
```

In our final program, though, we'll use INPUT statements to request the information from the user instead of using assignment statements. After a number of records have been stored, the arrays will look something like Table 3.

Now that we've chosen a way to store our data, it's fairly obvious what the routines which maintain and access the file will have to do. We'll keep track of how many members we have so far (0 to begin with, 6 in Table 3); then if we want to add a new member's record, we fill the information into the next available array location and add one to the number of members. To update a member's record, we start at array location 0, and see if N$(0) is the member we're looking for. If not, we look at N$(1); if that's not it, we look at N$(2), etc. Eventually we'll come to the right place and make the desired change. To generate a mailing list, we go through the arrays one member at a time, printing out the names and addresses of those who meet the criterion (either having a "YES" in their L$ field, or owing dues soon, or having a certain kind of system).

Looking over things so far, we might feel pretty good. All our desired functions seem possible, even fairly easy, to program. We might even pride ourselves on the fact that if a member discovers that we have an error in his or her data, we have an easy way to correct it – by using the update feature. (For some insane mysterious reason, some commercial data gathering organizations don't seem to cope with this problem very well.)

But before we plunge ahead and code these schemes, we should think them through again, especially worrying about what sorts of errors *can* creep into our system. For instance: (1) What if there's a mixup and the same new member gets entered in twice? (2) What if we go to do an update and misspell the name accidentally? (3) What if we were using assembly language and limited names to having no more than 24 characters as suggested in Table 4, and the user enters a name that's too long? (4) Can you think of any more problems that we could have? (Unfortunately, there's a couple of biggies lurking in here. See if you can spot them.)

Problems (1), (2), and (3) all involve input data that doesn't fit the assumptions we've made. It's crucial to design programs so they don't blindly plunge ahead using invalid data. People make loads of typing mistakes as well as have mental lapses. It's a corollary of Murphy's Law that if your program *can* blow up on invalid data, sooner or later it will.

The solution to error (1) is to have our program search the data file to see if there is already an entry for the "new" member instead of just blindly adding a new record in. That won't involve much extra programming effort because we already have to be able to search for a particular name to do the update operation.

The solution to problem number (2) is to be sure that our search routine doesn't look farther into the arrays than the number of members, and if it comes to the end without finding the desired name, to inform the user of

---

The problem of storing records and manipulating files is a very widespread one. Even though we're dealing with a specific example here, the techniques we'll develop can be directly used in many other situations.

To name a few:

In a RTTY contest, you may want to keep track of the stations you've already worked.

Your club may want to keep a file of radio-electronics supply houses, storing name, address, type of material offered, people's experiences dealing with them, etc.

You could create a bibliography of reference books and magazines.

A store may want to keep a file of customers, storing name, address, previous purchases, needs, etc.

Etc.

Table 1.

that fact.

Finding a solution to problem (3) is more bothersome. One solution would be to redesign the data structure so it allows more characters per name. But that would require more memory, most of which would be used to store blanks at the end of normal sized names. Another solution would be to redesign the program so that it implements a string-like (variable length) data structure. But that would be a lot of work. A compromise is to have the program count the number of characters in each name that's entered, and if the count exceeds 24, to ask the user to supply an abbreviation. The last solution isn't perfect (what if two people abbreviate the name differently?), but it seems less offensive than having the program arbitrarily chop off part of someone's name.

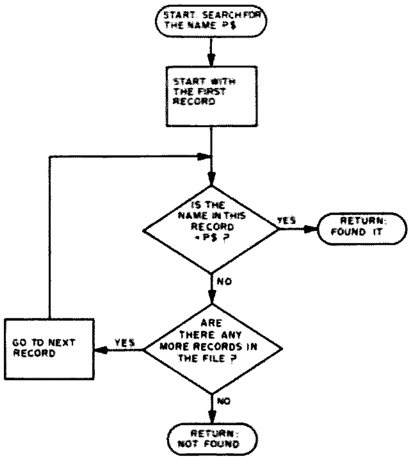

Fig 3.

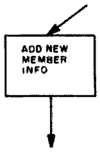
Now that we've thought over the basic techniques we'll use, and have anticipated some of the rough spots, we can start designing the program in earnest. The main thing it has to do is repeatedly accept commands from the user and carry them out. See Fig. 1.

Now we can refine our plan by breaking down each of the boxes into finer and finer detail, ultimately converting each to some sequence of Basic statements.

Let's start with the one that says



To carry it out, we need to get the new member's name, look through our file to make sure it's not already there, and if it's not, fill the new member's information into the arrays. Let's use a variable C (for "member count") to store the number of members. Since arrays in Basic start with position 0, location C in the arrays will be the location of the next empty spot. That means we can fill the new information into N$(C), A$(C), ... ,L$(C). Finally, we add one to C since now there's one more member in the file. If that doesn't seem clear, draw the arrays out and go through a few cases by hand to make sure that C is updated at the right time. See Fig. 2.

Now we're starting to roll. The only thing left to specify is the flow chart box that says "search file for that name." The new name has been assigned to the string variable, "P$." The flow chart is shown in Fig. 3, and here's the translation of the flow chart into Basic. Notice that we've written it as a subroutine since we're going to use it in two different places. It communicates its results by leaving the variable F with the value 0 if the sought-for name wasn't found, and with the value 1 if it was. In addition, if the name *was* found, the variable I will be left with the subscript value of the desired record.

```
1000 REM: SEARCH SUBROUTINE
1010 REM: LOOK FOR THE NAME "P$" IN THE
1020 REM: ARRAY OF MEMBER NAMES ("N$")
1030 REM: "C" IS THE NUMBER OF ENTRIES.
1040 REM: "I" IS THE SUBSCRIPT OF THE CURRENT RECORD.
1050 REM: RETURNS F=0 MEANS "NOT FOUND"
1060 REM:         F=1 MEANS "FOUND"
1070 LET I=0
1080 IF P$=N$(I) THEN 1140
1090    LET I=I+1
1100    IF I<C THEN 1080
1110 REM: DIDN'T FIND IT
1120 LET F=0
1130 RETURN
1140 REM: FOUND IT. IT'S IN LOCATION "I"
1150 LET F=1
1160 RETURN
```

Things still seem to be going all right, so let's forge ahead and convert our "add new member info" flow chart into Basic.

```
2000 REM: SUBROUTINE TO PROCESS "NEW MEMBER" COMMAND
2010 PRINT "WHAT'S THE NEW MEMBER'S NAME";
2020 INPUT P$
2030 REM: USE SEARCH SUBROUTINE TO PROTECT
2040 REM: AGAINST DUPLICATE ENTRIES.
2050 GOSUB 1000
2060 REM: IF F=1, P$ WAS FOUND.
2070 IF F<>0 THEN 2230
2080    LET N$(C)=P$
2090    PRINT "STREET, APT.#";
2100    INPUT A$(C)
2110    PRINT "CITY,STATE,ZIP";
2120    INPUT B$(C)
2130    PRINT "MONTH,YEAR DUES ARE PAID UP TO";
2140    INPUT M$,Y$
2150    LET D$(C)=M$+","+Y$
2160    PRINT "WHAT KIND OF SYSTEM";
2170    INPUT S$(C)
2180    PRINT "DOES ";N$(C);" WANT ON MAILING LIST (YES,NO)";
2190    INPUT L$(C)
2200    REM: INCREMENT "C"--WE HAVE A NEW MEMBER!
2210    LET C=C+1
2220    RETURN
2230 REM: ERROR OF SOME SORT.
2240 PRINT "SORRY, BUT ";P$;" IS ALREADY A MEMBER."
2250 PRINT "MAYBE YOU SELECTED THE WRONG COMMAND."
2260 RETURN
```

Again, everything went pretty smoothly, but let's look over the code closely to be sure there are no typos or other obvious errors. Everything looks pretty good ... but wait! What's that? Statement 2210 looks a little funny all alone there. It's not very common to increment a counter without checking to make sure it's still within the proper range. What were we thinking? Hmmm. "C" is the number of club members. Of course our *club* wants as

---

Array

An *array* is a collection of memory cells, individual members of which may be referenced by specifying the array name plus a subscript value (index).

In Basic, Fortran, Algol, etc.	*In Assembly Language*
Usually you need some sort of "DIMension" statement telling how long the array is: DIM M(50)	When writing the program you reserve a contiguous chunk of memory of the appropriate size.
Each array has a name: M	Each array has a *starting* (or *base*) *address* which is the memory location of the first byte in the chunk you set aside.
Individual locations are identified by listing a subscript expression after the array name: M(24)	Individual locations are accessed by adding an *offset* (or *index*) to the starting address. Often the machine architecture includes an *index register* for this purpose.
The subscript expression may be computed from other values: M(N*2+J)	The index can be varied depending on other values.

M(0)
M(1)
M(2)
M(3)
M(4)

Table 3.

many members as we can get, but how many can our *program* handle? The way we declared our arrays, we left room for 101 members, but was *that* right? What if we get *thousands* of members? We can't just keep increasing the array sizes in our DIM statement — surely not that many records will fit in memory at once. But if they won't, our program won't work! Oh no!

Let's try to suppress that old sinking feeling and figure out what's going on here. Suppose the average name has 20 characters in it and the average address 50. The dues expiration date takes up about 9 bytes, the system description about 25, and the mailing list info takes 3. That's about 107 bytes per record. We're running 8K Basic and our computer has 16K bytes in all. That means we'll be able to fit about 8K/107 ≅ 80 records before completely running out of space. That won't do. Maybe we've been extravagant in the way we've organized our data.

There *are* a few things we could do to free up a little more memory (see Table 5). We can't cut out any of the data stored about the members without making our program pretty much useless. We could throw out the REMark statements, but that won't make much difference (we might squeeze in 2 or 3 more records that way).

We *can* convert some of the string values to numbers. For example, the mailing list entry could just as well be 1 or 0 instead of "YES" or "NO", and we could list the dues payment date in the form 1978.06 instead of "JUNE,1978." In fact, we can do both of those and cram both values into one array by leaving the date positive if the member wants to be on the mailing list and making it negative otherwise. That way,

-1978.02 is equivalent to DS(0)="FEB,1978"
LS(0)="NO"
and
+1979.03 is equivalent to DS(0)="MARCH,1979"
LS(0)="YES"

If we do that, though, we want to be sure that no one who uses the program has to know about it (there'd be too many chances for error, plus who would want to explain it?). This would require subroutines to pack and unpack the information. Unfortunately, even that won't help very much (our club is very optimistic about our eventual size). The only option is number 6. We'll have to keep most of the data on an external storage device and bring it in in manageable sized chunks to process it. Maybe if we'd been a little more awake at the beginning (the Programmer's Lament), we could have seen that that was what we wanted to do all along — surely we weren't going to keep all the records in memory all the time! The Startrek freaks would have had our heads!

There are a number of different types of external storage we could use (including paper or mag tape, disc, etc.) and a number of different ways of interfacing to each. We can't go into them all here; instead I'll try to outline what to do assuming that we're using a cassette recorder. On most versions of Basic, you'll have to write machine language routines to handle the required I/O. You can either write machine language equivalents to the INPUT and PRINT statements, or you may want to write a routine that makes your cassette recorder look like the terminal to Basic. In that case, you would call the machine language routine, then INPUT from or PRINT to the tape, then call the routine again to restore the terminal as the I/O device. On the other hand, you may be able to connect your cassette recorder in parallel with your terminal (similar to the way Teletype paper tape equipment is related to the keyboard).

At any rate, let's assume that you have some way of getting records in and out of memory.

Interestingly, this doesn't force very many changes in our program. We just need another test here and there: a test which determines if we've finished searching through the records currently in memory. If we have, but still haven't found the record we want, we call a subroutine which reads a new memory-full of records from tape and forge ahead.

Now we have a scheme that's sure to work and we can push on, refining it and coding it . . . or do we? If our previous disaster should have taught us anything, it's not to get carried away with what seems to be a good idea without having a long hard look at it. We should review our plan, taking care to check not only whether we think we can

---

What if your version of Basic doesn't allow arrays of strings?

— If it allows string variables, but not arrays of strings, you can use a two-dimensional array to store names by ripping the string apart, converting each character in the name to a number (there should be a built-in function called something like ASC which does that) and storing them one by one. (On most versions of Basic, *two* characters will fit in each numeric variable.)

DIM N(100,24),A(100,24), . . .

N(I,J)

	J=0	J=1	J=2	J=3	J=4	5	6	7	8	9	10	11	12	13	
I=0	J	O	S	E		A	L	C	A	L	A				. . .
I=1	S	A	N	D	Y		S	W	E	I	C	K	E	R	. . .
I=2	A	N	T	H	O	N	Y		T	E	M	P	L	E	. . .
I=3	S	U	S	A	N		B	U	R	G	E	S	S		. . .
I=4	B	I	L	L		M	E	K							
I=5	S	A	M	.											
I=6			.	.											
	.	.	.												
	.	.	.												
	.	.													

— If it doesn't allow string variables, you're out of luck, and will have to use assembly language.

— In assembly language, simply allocate 24 or so bytes per array location, and store the characters one per byte, filling in any unused bytes with blank characters.

Table 4.

Seven ways of cutting down on memory usage listed in order of decreasing disgustingness.

0. Give up.

1. Decrease your ambitions, throw away some of your program's capabilities.

2. Throw out REMarks and cram more than one statement onto each line. Note: Since both of these make your program harder for people to understand, be *sure* to keep good written records of what the program does and how it does it.

3. Use abbreviations in string data, or convert string values into numeric values. Note: The latter saves a little space – the space used to store string length information.

4. Cram more than one piece of data into a single variable. Note: Be sure to include packing and unpacking subroutines so users don't have to deal with conglomerated, messy values.

5. Revise the basic algorithm so that it (re-)computes values instead of relying on stored data. One example: Instead of storing calender dates and days of the week, look up and use an algorithm which computes them.

6. Use external storage devices.

Table 5.

write the code, but also to see whether it's really practical. In fact, with a system like our club's, our new plan *isn't* practical. Our cassette tape interface runs at 300 baud – about 25 characters a second. That means each memory-full of membership records (each 80 records) will take almost five and a half minutes to read in.

Suppose we have 200 members and one of them tells us that there's a mistake in his mailing address. Suppose further that he's a recent member and his record is near the end of the file. The way we have it now, the person using the program to do the required update will have to put on the first tape, sit there 5½ minutes, find (groan) that the desired record wasn't on that tape, get the next one, wait 5½ minutes, etc. It would be so gruesome that no one would ever want to do the updates that were supposed to be one of our system's big features.

Fortunately, there's a way out and it won't require any major changes to anything but our search algorithm. Unfortunately, we'll have to wait until next month to find out what it is so we can (finally) complete our club's record keeping program.

What have we accomplished so far? We've taken a realistic, fair-sized problem and broken it down into small manageable parts. We've stepped back (well OK, *fallen* back) and analyzed how the system will work in practice – and found our plan wanting. Along the way, we've seen techniques for using arrays, organizing data, and we've seen a search strategy that is useful when dealing with small amounts of data. We've seen some techniques for saving memory space. Most of all, we've had a mind's eye view of the agony and the ecstasy of developing software. ■

Hints about next month's search strategy:

– If telephone directories were organized like the scheme we've used so far (the names aren't in alphabetical or any other particular order), would you be willing to use one?

– If somebody asks you to guess a number from 1 to 100 that they're thinking of, and they tell you "high," "low," or "got it" after each guess, what's the most guesses you'd ever need?

OSCAR Orbits on Your Altair

-- the software you've needed

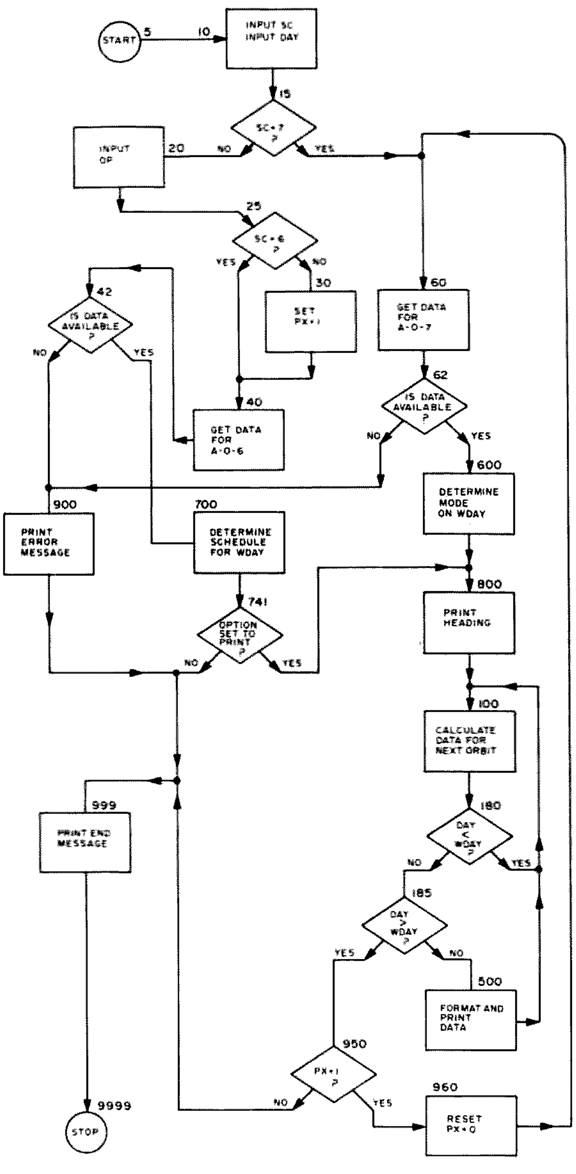

Fig. 1. Flow chart. Numbers in bold are equivalent line numbers.

Joe Kasser G3ZCZ

Altair owners rejoice. You can now obtain individual orbital predictions for the AMSAT-OSCAR 6 and 7 spacecraft on your machine, for any day of the year, using the following program.

This program is written in ALTAIR BASIC (8K) and uses only about 1750 bytes of User Program Memory Area.

The program gives you the following options: spacecraft 6 – AMSAT-OSCAR 6 orbits only; spacecraft 7 – AMSAT-OSCAR 7 orbits only; spacecraft Ø – both spacecraft orbits.

If spacecraft 6 or Ø are chosen the following options are available: Ø – Print the orbits; 1 – Print the orbits only if the Spacecraft is scheduled for communications use that day.

The opening dialogue is as follows: The program asks for the day, spacecraft and if necessary the option. It then thinks about it for a while and prints out the required data. Several examples of such listings are shown.

The program works in the following manner, outlined in the flow chart of Fig. 1. The initial dialogue gives it the wanted day (WDAY) and the spacecraft (SC). Next it picks up the orbital parameters depending on the spacecraft chosen. The data for AMSAT-OSCAR 6 are stored in lines 40 and 45, and that for AMSAT-OSCAR 7 in lines 60 and 65.

A test is performed at line 42 or 62 to determine if data is available for the wanted day. If the "both spacecraft" option has been chosen, a "print" flag (PX) is set at line 30.

Next the condition of the

spacecraft on WDAY is computed. For AMSAT-OSCAR 6, the actual day of the week that WDAY occurs on is calculated (SDAY) and compared with the spacecraft operational schedule in the subroutine starting at line 700, and the program ends if option (OP) zero was chosen and WDAY is an OFF (i.e., AMSAT-OSCAR 6 is not available for communications use) day.

Similarly, the mode that AMSAT-OSCAR 7 will be in on WDAY is computed by the subroutine starting at line 600.

The table headings are then printed (subroutine starting at 800 and line 75).

The main loop starts at line 100. The orbit (RB) is incremented and the equatorial crossing (XS) is updated by one progression amount at line 100. If the value of XS should become greater than 360°, it is fudged by the routine at lines 125 and 130. The time TM is

```

incremented by adding the period (PD) at line 140. Note PD and TM are in minutes. If the new time is greater than 1440 minutes (24 hours), it is fudged and the day (DAY) count incremented at lines 145 and 150. Line 180 is the print control line, for if WDAY is greater than DAY, printing is inhibited.

This program calculates the orbital parameters for any wanted day (WDAY) by starting with a reference day and updating it by successive additions. Line 185 detects that all the orbits for WDAY have been printed and stops the program execution.

The routine beginning at line 500 formats the data for the printout at line 520. The value of TM in minutes is converted to hours and minutes and formatted to print out only two decimal places (the formatted value becoming TF). The equatorial crossing location (XS) is also similarly formatted (the formatted value becoming XP). After the data is printed, the program computes the parameters for the next orbit and so on.

After the day's orbits for AMSAT-OSCAR 6 have been printed or inhibited (depending on OP), the value of PX is tested. If it is Ø, the program exits. If it is 1, PX is reset and the orbits of AMSAT-OSCAR 7 for WDAY are calcuated and printed.

Spread out in the program are examples of string manipulation. At line 5 the strings C$ and E$ are set up. B$ is set to one of a number of possible states at lines 620, 645, 740 or 750, and E$ is changed at line 660. This allows the fixed "print string" function of line 820 to print a number of different messages depending on how the strings have been set up. This technique uses less memory space than routines that set up the strings individually and require separate print lines in the individual subroutines.

This is a pretty simple-minded program. It can be modified in many ways. Some suggested ones are as follows:

1. Only print orbits in range of station.
2. Print ascending mode orbits only in the case of AMSAT-OSCAR 6.
3. Add antenna pointing data.

If anyone is interested in a paper tape of the program listing, I can supply one for $1.00 and an SASE. ■

ASCII/Baudot Converter for Your TVT

-- series or parallel to boot

The schematic diagrams for the 3321 Baudot input option are shown in Figs. 1 and 2. The Baudot input option is used to receive serial Baudot, convert it to parallel, and make a code conversion to ASCII which can be used with the 3320 display unit. The three main circuits are a UART and two 8223 programmable read only memories (PROMs), which are programmed for the Baudot to ASCII conversion. The UART must be clocked at 16 times the baud rate. This clock, and therefore the baud rate, is dependent on the setting of the divide by N inputs of plug 2. The formula for setting the inputs to a one or a zero is:

$$256 - \frac{198{,}080}{16 \times \text{baud rate}} =$$

the setting of the jumpers

Note that the setting of the jumpers must be converted to binary before the dip plug is actually wired to ones and zeros.

Example: For 100 baud (132 wpm),

$$256 - \frac{198{,}080}{16 \times 100} =$$

$$\frac{198{,}080}{1600} = 137$$

Note that 137 is (lsb) 1001 0001 (msb) in binary.

The pins of the dip plug can be hardwired according to the above formula. Table 1 gives the settings and dip plug pin numbers for some common speeds. You could also run the wires from the plug to a switch so that you could have many speeds.

The output of these dividers (circuits 3 and 4) is pin 15 of 4 and is sent to the UART to clock the input data in. The input data can be either a 60 milliampere loop, RS-232, or TTL compatible. If it is TTL or RS-232, the data is buffered with Q1 and sent directly to the UART. To allow the transistor to switch from high to low, the output of the loop data in-

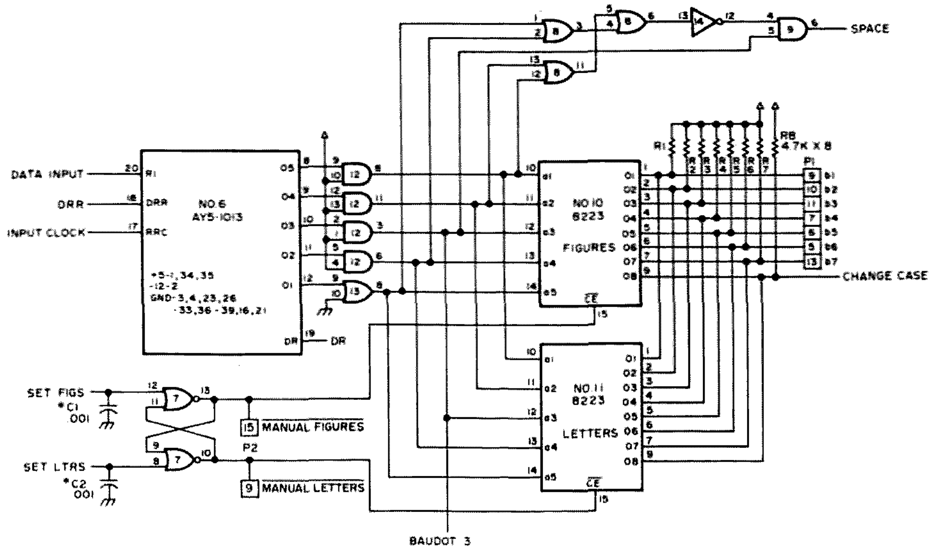

Fig. 1. UART and control. C1 and C2 are tack-soldered to the bottom of earlier boards. Newer boards have provisions for these capacitors in their artwork.

verter must be high. Therefore, the input is grounded if TTL or RS-232 is to be used. If the loop is used, diodes D1-D4 form a full wave rectifier whose output is regulated to 5.1 volts by D5. The 68 Ohm resistor limits the current through the LED inside the circuit (which is between pins 1 and 2). When this LED has current through it, it emits light which turns on a phototransistor, also inside the IC. This shorts pin 5 to ground, causing pin 10 of 14 to go high. Thus, with loop current flowing (mark condition), the input of the UART is high. The integrated circuit is an optically-coupled isolator, and is used to make sure that the high voltage loop does not get to the TTL circuits.

This input data is sent to pin 20 of the UART. When this data drops to a space condition (logical zero), the UART loads the data, one bit at a time, into its output register, and brings pin 19 (data ready) high. This sets a flip flop (circuit 7) whose $\bar{Q}$ output (pin 4) goes low. If the character was not a change case code, this becomes the strobe line to the 3320 display unit. As soon as the strobe has been received, a short strobe received is sent back to the UART board, which resets this flip flop. The $\bar{Q}$ output of the flip flop is also sent back to the UART to reset the data ready line. The data is still, however, available at the UART's outputs.

This data is sent to a buffer so that it can drive several TTL loads. From there it goes to the PROM code converter and to a circuit whose output (pin 6 of 9) goes high if the input data was a space. The outputs of the PROMs are open collector, and only one set of outputs is enabled at one time. One PROM is used if the unit is in the letters case. Likewise, the other one is used if it is in the figures case.

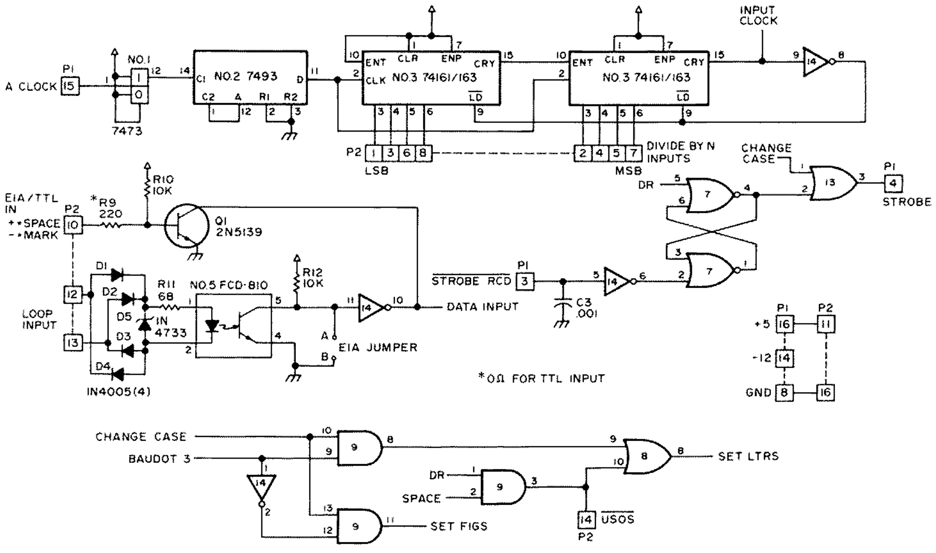

Fig. 2. Interfaces.

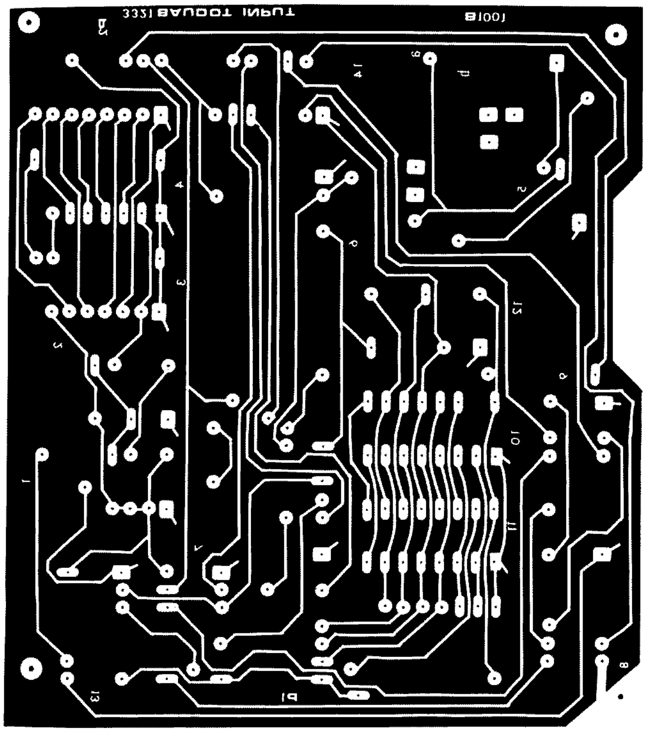
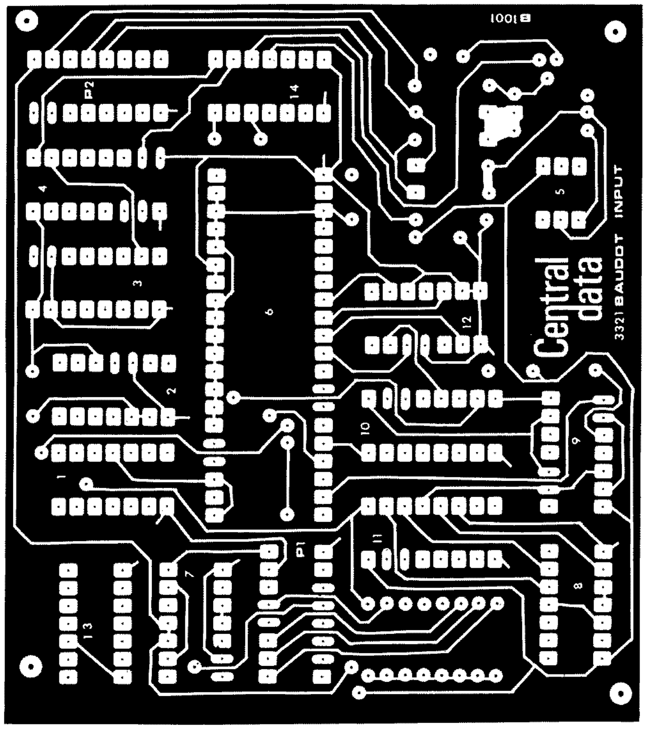
WPM	Baud	lsb	msb
P2 pins		1368	2457
132	100	1001	0001
100	73.7	1111	1010
75	57	1111	0100
66	50	0100	1000
60	45.5	0000	0000

Table 1. Settings of the divide by N inputs for common baud rates. The 60 wpm setting is not exact, but it is close enough such that no errors will be caused.





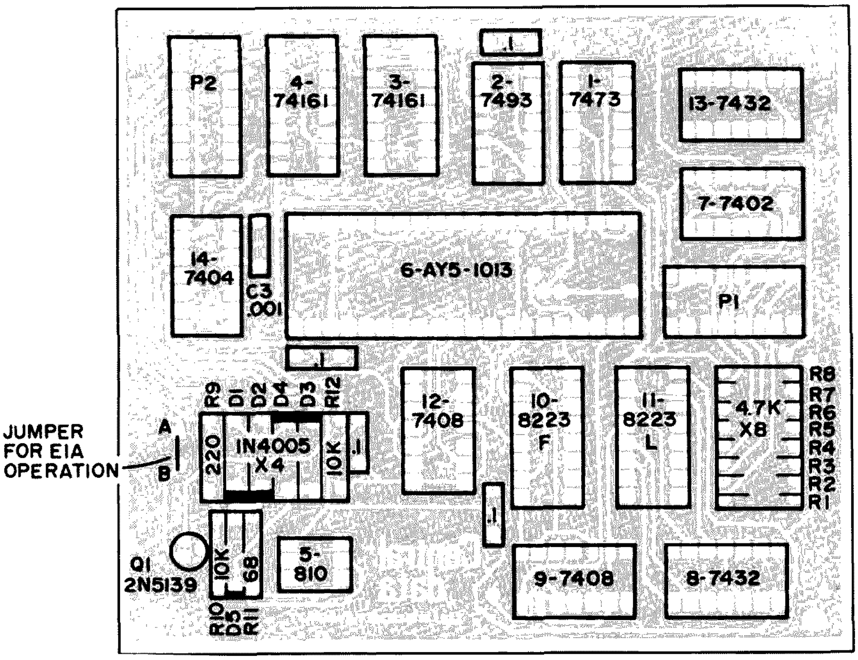


Fig. 3. PC board and parts layout.

The PROM that is enabled has pin 15 brought low by the other flip flop in circuit 7 (pins 13 or 10). The output of the code converter consists of 7 bits coded in ASCII and one bit that is high only if the case is to be changed. Table 2 has the ASCII and Baudot codes, as the PROMs convert them. The ASCII bits are sent to the 3320 display board through a buffer consisting of AND gates, but the change case bit is decoded with the Baudot data to decide whether to shift into figures or letters. If bit 3 of the Baudot data is high, the unit goes into letters shift, while if it is low it goes into figures shift. The unit can also go into letters if a space is received, and unshift on space is not inhibited (pin 3 of 9 is not grounded). If a figures shift command is received, pin 11 of 9 goes high, which sets a flip flop at pin 12 of 7. This brings 13 of 7 low, enabling the figures PROM. If a letters shift command is received, or if USOS is enabled and a space is received, pin 8 of 8 is high, which sets the flip flop at pin 8 of 7. This brings pin 10 of 7 low, which enables the letters PROM. The unit can be put manually into figures or letters by grounding the enable pins of the desired PROM. This will set the flip flop accordingly.

Assembly

Refer to the first four paragraphs of the main logic board's assembly procedure for basic information pertaining to the assembly of this kit. Fig. 3 is the placement drawing for all of the components on the Baudot Input Board. All parts have their type number and component number (as used on schematics) printed on the drawing.

1) Mount and solder all resistors and diodes to the board. The banded (cathode) ends of the diodes are marked by a square pad on the top of the board. Mount all resistors and diodes before soldering them, as a way to check your work.

2) Mount and solder the 40 pin socket and the two 16 pin sockets at the positions marked UART, P1, and P2, respectively.

3) Mount all the TTL integrated circuits on the board and, after checking their placement, solder them in. The placement of pin one is denoted by a small "flag" coming off of that pin's pad – along with a square pad on the top of the board.

4) Plug the 40 pin UART into the socket, being careful not to bend the leads.

5) Mount all capacitors and the transistor, being sure to polarize the electrolytic. The

Table 2(b). PROM coding, FIGURES PROM.

square pad on the top of the board denotes the positive end of the capacitor and the emitter of the transistor.

Before attempting to operate this board, the main logic board must be completely working.

Operation

To hook the Baudot Input Board to the display board and to a TTY system, there are two 16 pin sockets and dip plugs that are used as connectors. The cable with two dip plugs that was shipped with the Baudot board is used to connect the large display board to the Baudot Input Board. This is accomplished by connecting the input socket of the main board to the P1 socket of the option board. To hook the system to your teletype system, the dip plug with cable contained in the main logic board's kit is used along with the P2 socket.

The pins of the P2 socket have the following designations:

1 – b1
2 – b2
3 – b3
4 – b4
5 – b5
6 – b6
7 – b7
8 – b8
9 – $\overline{\text{MANUAL LETTERS}}$
10 – EIA, TTL input
11 – +5 V
12 – Loop input
13 – Loop input
14 – $\overline{\text{Unshift on Space}}$
15 – $\overline{\text{MANUAL FIGURES}}$
16 – Ground

The specifications for the input signals are:

TTL – 0-.8 V = mark
2.4-5 V = space

EIA – +3-+15 V = space
-3--15 V = mark

Loop – 0-2 mils = space
20-80 mils = mark

The pins marked b1-b8 represent the divide by N inputs and are used to set the speed of operation. These wires can be hardwired to one speed or can be run to a switch where many speeds can be selected. The procedure for figuring the correct jumpers is given in the theory of operation section.

Conclusion

If you decided to build all three boards, you now have a near universal display unit which can receive serial or parallel ASCII or serial Baudot. In any case, I hope that you enjoyed this project as much as I did. ■

Parts List (Baudot)

1 – 7404
1 – 7402
2 – 7408
2 – 7432
1 – 7473
1 – 7493
2 – 74161 or 74163
2 – 8223 (coded)
1 – AY5 – 1013 UART
1 – FCD – 810
4 – 1N4005
1 – 1N4735
1 – 2N5139
2 – 16 pin dip sockets
1 – 40 pin dip socket
1 – double ended dip plug
3 – .001 disc capacitors
4 – .1 disc capacitors
8 – 4.7k resistors
1 – 68 Ohm resistor
1 – 1k resistor
2 – 10k resistors
1 – 220 Ohm resistor
1 – Baudot Input circuit board

A kit of the above parts is available from: Mini Micro Mart, 1618 James Street, Syracuse NY 13203.

EDITORIAL BY WAYNE GREEN

from page 4

El Toro Crappo. After a couple days of driving all over the Bay Area, I have to report that you won't run into a nicer bunch of people. I never heard any bad language; I checked with one group after another on the channels and they said that, yes, a couple years ago they used to be annoyed with such characters, but they were long gone. I did hear someone jamming a channel for a bit, but the reaction of the others on channel made it apparent that this was unusual.

The one glaringly obvious aspect of CB in San Francisco was the low level of interference on most channels compared to many cities I have visited. There seem to be very few CBers in the Bay Area compared to back East. I was able to get on many channels and talk from my puny mobile setup (with a miniscule antenna) for many miles without being stepped on. I was absolutely amazed.

Even the highway channel (#18 there) was reasonably dead much of the time . . . it was so quiet that it took me a while to find out which channel was being used for traffic reports.

It is a pity that the FCC is so out of touch with their own services.

REPORT FROM DENVER

After getting thrown off the program, I decided not to bother with the expense of going to Denver . . . which turned out to be a shrewd decision, according to a report from an exhibitor.

This exhibitor drove a couple of days to get to Denver and found first off that his confirmed reservations were screwed up. After a lot of hassle, they finally gave him his room. Then he started looking for the material he had shipped out to be held for him at the convention . . . the stuff he was planning to sell and the reason he went all that way. After following a very difficult trail, he discovered that the firm he had been told to ship the stuff to had gone out of business three months earlier. The new firm received his shipment, held it ten days and then returned it. So all he had to sell was what he had brought with him in his car.

The booths were $300 each . . . and that is extremely high for ham convention booth space. He found his booth down in the cellar, not with the rest upstairs. There were a few others down there, too. Worse, there were no signs in the upstairs exhibit area to tell anyone about the cellar exhibits . . . and there was little light for some of the cellar booths. The convention committee refused to do anything about either problem, despite many tries at getting help.

Our hero took on the hotel again and finally managed to get them to get some lights set up so visitors, if any, would be able to see his booth. Then he tried again to get help getting some signs to let convention-goers know there were some exhibits in the cellar . . . no good. Finally, in desperation, he made some signs himself and put them near the elevators. This brought a few hardy souls to the remote area, but about half of the hams never found the place.

Not that things were going all that well with the regular exhibits. It was pretty lonesome there, and one manufacturer got so fed up that he gave up by Friday night and pulled out for home. Even the computer exhibits were empty most of the time . . . and computers have been pulling the best of all exhibits at conventions this year. Estimates by exhibitors put the

attendance at a maximum of a bit over 1000 for Friday, and not much more than that on Saturday . . . and on Sunday virtually no one showed up so the exhibitors packed up and went home.

I'll be interested in how the show looked to the convention-goers . . . so drop a line to *73* with your views on what was good and what bad about the ARRL National Convention at Denver.

CB AND AMATEUR RADIO

As previously reported, ham clubs are now finding that about 80% of the new faces appearing for their Novice and General courses are coming from the CB ranks. This is natural . . . CB is an easy entry into radio two-way and a fellow would have to be a fool not to get his feet wet with it for starters. CB is fun, as about 20 million people have discovered. Of course we amateurs know that hamming is even more fun, but getting the word out is difficult.

In years gone by, I wrote a ham column for *Electronics Illustrated* as a way of enticing newcomers into amateur radio. That magazine evolved into *Mechanics Illustrated* and the ham column demised . . . pity. It seemed to me that we really needed a way to get hamming known to CBers . . . so I stewed about that for quite a while . . . and came up with an answer.

My column, "CB Radio Today," is being distributed nationally to newspapers. The column starts out telling about CB radio and then goes on to give the skinny on amateur radio. The results from the first few columns published (Boston, Galveston, and a few other cities) have been a massive influx of letters asking how people can get in touch with local ham clubs to get into the Novice classes.

WHAT CAN YOU DO?

You can help a lot with this . . . and in several ways. First, you can get after your local paper editor to run my column . . . he has nothing to lose for the paper advertising department should be able to get ads from Radio Shack and other CB dealers in the area to pay the freight. If you are willing to go see your local editor, drop me a note and I'll send you some sample columns to show him. The reader response has been fantastic . . . many write in to say they are saving the columns in a notebook for reference.

Secondly, you can make sure that your club has a Novice training program and that this is made known on a poster in all local radio stores. All I can do in my column, which is distributed nationwide, is to tell CBers to look up their radio distributors in the Yellow Pages and go there for info on classes.

The FCC admits that the club program for training Novices has already turned the tide and the number of amateurs is growing for the first time in twelve years (since "incentive licensing" was proposed). With large empty VHF bands, we need to keep plugging for more hams and more activity. You can do your bit by seeing that we get PR in your papers . . . and my CB column is the best way to keep this PR coming week after week.

Write to "CB Radio Today," Peterborough NH 03458 for sample columns and info.

TALK SHOW

It looked like a winner! A radio talk show with a ham MC, an active CBer, a representative from the FCC, an ARRL director, and Wayne Green on the telephone to talk about both CB and hamming. What a fantastic opportunity to help a few thousand more people get to know about hamming.

Things bombed out badly. The CBer had little background so couldn't add much to the pot. The FCC chap was an old time two letter call ham, so he and the ARRL director got into esoteric ham stuff of no possible interest to the general radio listeners. Instead of explaining about the *fun* of amateur radio and how to get started in radio communications via CB, the director got right into a long blast on how amateur radio was *not* a hobby, it was a *service* and was regulated by the ITU (whatever that was).

The FCC rep was about as anti-CB as hams come. I passed up the chance

to ask him if he was active on CB because it was obvious he wasn't. CB was a bunch of law-breakers using bad language, period. Well, it might be okay back East, but where he was it was terrible. What can you say? I'll be in his city in a few days and I'll see for myself, for I will be bringing along a CB rig as well as my trusty 2m mobile. Like many other hams, I find CB invaluable for travel, though I seldom use it at home.

Since the general public is now aware of CB, but not really familiar with it, it seems to me that our best bet when we have a chance to get on radio or television is to let them know the benefits of CB . . . and then the further benefits of amateur radio . . . emphasizing that getting started in either is simple and not expensive. A lot of people have the idea that hamming takes huge investments in equipment, and they are surprised to find that amateur radio is really a very inexpensive hobby compared to most (like sports cars, boats, travel, blonds).

TRUMPET BLOWING

While at times I anguish over the time it takes for change, I suppose I should be satisfied that changes are (at last) going in what I consider a good direction . . . such as the recent granting of Novice privileges to Techs. The petition for that change was put into the FCC so many years ago that few of you probably have any notion of who was behind it . . . probably ARRL, right? To set the record straight, that was submitted by *me* around five or ten years ago . . . I forget when.

It is with some irritation I listen to tapes of ARRL officials going around to ham clubs saying that Wayne Green proposed "incentive licensing," without a doubt the most destructive rule changes in our history. It totally stopped the growth of amateur radio for over ten years! When ARRL proposed it, I fought it . . . when they petitioned the FCC, I fought it . . . and history, for whatever satisfaction there is in that, proved all of my arguments against it right. It was a bomb. I must admit that I feel a sense of achievement at the gradual veering away from the restrictions of incentive licensing.

The FCC is in the throes of trying to de-regulate amateur radio. This is a direct result of the hearing I organized a couple of years ago . . . the first of its kind ever put on by radio amateurs. Many of the particularly restrictive rules of which we complained have already been eased . . . the time, effort and expense of the hearing have been amply repaid. Yet we have, I feel, a long way yet to go. It is apparently so alien to a government agency to try and cut back on rules that every time they make a swing at it they go half way and falter.

One of my other petitions, which has been sitting at the FCC for several years, is the proposed Communicator license plan. I put that in to counter the EIA push to take our 220-225 MHz band as much as anything. It still remains to be seen whether this is going to work. While there is growing enthusiasm over my proposal, on the other hand we have Jerry Ford and the White House putting on the pressure for CB to get part or all of the ham band.

FORD IN OUR FUTURE?

When I got word that the renewed pressure for grabbing our 220 MHz band was coming from the White House, I got in touch with the Office of Telecommunications Policy there and pinned them down. They swore that they were not in favor of the grab, but that the pressure was coming from considerably above them in the White House. It was enough for me to go out and get a jar of Skippy and see if I could get the taste of things to come.

Yes, I know ARRL/*QST* has been very adamant that we not discuss religion or politics on the air . . . and it goes against many generations of hidebound Yankee Republican Conservatism for me to say it . . . but it sure looks to me as if a vote for Ford/Dole is a vote for CB on 220 MHz. From the polls and from my own reaction to Ford, I doubt if we have any serious worries. Apparently there are several million people who are just as enthusiastic about Jerry as I am. Pass the Skippy.

The Smoke Tester

- - power supply checker outer

This tester allows full power (smoke) testing of large or small power supplies *before* they are put on the rig. It will tell how many volts at how many Amps the supply can deliver, and what kind of voltage loss to expect under load. It can also help determine some of the attributes of low voltage power transformers, without having to wire them into a power supply.

It consists of 2 or 3 transistors, a pot, a couple of meters, a few diodes and some loose hardware. Don't forget the heat sink. If you wish to be formal about it, then add a chassis of some kind.

Fig. 1 shows the basic circuit. As the wiper is moved toward the plus, more current flows in the base circuit. The external circuit looking into the collector/emitter sees a lower and lower resistance. The ammeter and voltmeter give an idea of Watts cooking (sorry about that). The diode allows less than perfect attention to the polarity of the incoming voltage. The resistor in series with the base limits base current to a safe value.

Although the transistor manual indicates that the 2N3055 is a "15 Ampere" transistor, 2 or 3 of them cleared like fuses when the collector current was slowly increased above about 11 or 12 Amps. The 10 Amp fuse was put in the emitter, and collector current excursions were limited after that.

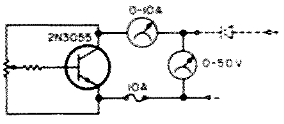

Fig. 1. Basic circuit.

Since power supplies capable of giving more than 20 Amps were to be tested, two 2N3055s were put in parallel. The fuses gave enough resistance in the emitters to help the transistors share the current in a more or less equal manner (at least there were no more creamed transistors).

A Darlington or piggyback configuration is used to reduce the power dissipation requirements of the pot. Ten Amps in the collector can require as much as ½ Amp in the base. Half an Amp times

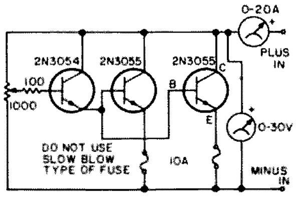

Fig. 2. Solid state resistor.

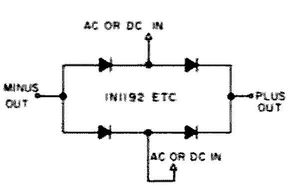

Fig. 3. Bridge rectifier.

several volts equals several Watts. The Darlington system reduces the input current by as much as 50 times. That figures out to about 10-20 mA for 10-20 Amps in the collectors, and makes the system practical.

Note that if the power supply is delivering 15 Amps at 13 volts, then something is going to have to dissipate 195 Watts. *Be sure* that the 2N3055s are on a large enough heat sink.

If a full wave bridge rectifier is placed in front of the tester, power transformers can be checked for voltage out versus current. That information would have saved a lot of time in the past.

Of course, there are single transistors around that meet the voltage, current, and power ratings of this tester.

If PNP transistors are used, reverse the polarity of the meters and diodes. ■

Social Events

ST PAUL MN
OCT 1-3

The '76 ARRL Dakota Division Convention will be held October 1, 2 and 3, 1976 at the new St. Paul Civic Center, 143 W. 4th Street, St. Paul, Minnesota. MARS, ladies' program, technical seminars, ARRL forum, FCC exams, Wouff Hong, W.A.M. Award. Large exhibit area with many new products, outstanding speakers, ARRL Headquarters personnel will be there, super full course banquet, and an ICOM IC-230 will be awarded to an advance registrant. Registration: $4.50 ($6 after Sept. 12). Among the featured speakers will be Wayne Green W2NSD/1, on "50 years of Ham Radio, 1936-1986."

LEXINGTON KY
OCT 3

The Central Kentucky Hamfest will be held on October 3, 1976 at the Countryworld Convention Center on I-75 between Lexington and Georgetown, Kentucky. Prices will be given away, including a special Novice grand prize. There will also be an indoor flea market. Talk-in on 146.16-76. Admission: $2.50 advance; $3.00 at the door; includes grand prize stub. Doors open at 8 am. For more information and advance tickets write: Hamfest, Box 4411, Lexington KY 40504.

WASECA MN
OCT 9

The Sixth Annual South Minnesota Swapfest – Minnesota's largest ham gathering – will be held Saturday, October 9, 9 am to 4 pm at Waseca Community High School. Talk-in on .94. Contact Viking Amateur Radio Society (VARS), Box 3, Waseca MN 56093, 507-835-2679.

ERIE PA
OCT 9

The Radio Association of Erie has just approved the date for its fall Hamfest and Flea Market on Saturday, October 9, 1976. This year's event will be held at the Kuhl Hose Company Grounds on Pennsylvania Route 8, 1½ miles south of I-90. Admission is free with a $1.00 per car charge for the flea market. The time will be from 10 am to 4 pm with a dinner to follow at 6 pm. For more information contact RAE, Box 844, Erie PA 16512.

SYRACUSE NY
OCT 9

The Radio Amateurs of Greater Syracuse will hold their annual Hamfest on Saturday, October 9, 1976 from 9 am to 6 pm at the Syracuse Auto Auction building on Route 11, 4 miles south of Syracuse. Tickets are $1.50 if purchased before October 1st and $2.00 thereafter. Food will be available, as well as a breakfast menu for early comers. The Lafayette Apple Festival is being held the same day and there will be buses to it leaving from the hamfest gate. The program will feature Dave Sumner of the ARRL, Frank WB2MFF, on "Microprocessors and Amateur Radio," a UNYREPCO panel, and a Navy MARS meeting. For tickets or further information, write R.A.G.S., Box 88, Liverpool, New York 13088.

OLD WESTBURY NY
OCT 10

The Electronic Flea Market sponsored by L. I. Mobile Amateur Radio Club (LIMARC) will be held Sunday, October 10, 1976, from 9 am to 4 pm at the N.Y. Institute of Technology, Rte. 25A and Whitney Lane. Admission $1.25 per buyer; $2.50 per seller, per space. Information call Hank WB2ALW, 516-484-4322. Talk-in on 25/85.

GAINESVILLE GA
OCT 17

The Lanierland A.R.C. Hamnic will be held October 17, 1976, at the Lake

Lanier Islands Dogwood Pavilion. Prize tickets $1.00 each. There is no registration fee but Lanier Islands charges $2.00 entry fee per car. Plenty of room for flea market, picnic and use of island facilities. Talk-in on W4IKR/4 146.07/.67. For additional information contact Paul Watkins W4FDK, Route 11, Box 277, Gainesville GA 30501.

SHARON MA
OCT 17

Sharon A.R.A. Auction will be held Sunday, October 17, 1976. Doors open at 12 noon. Auction starts at 2 pm. Location: Sharon Community Center, Massapoag Ave., Sharon, Mass. Free refreshments. Club takes 15% commission.

TORONTO CANADA
OCT 22-24

The Radio Society of Ontario will hold its 9th Annual RSO Convention on October 22-24, 1976 at the Don Valley Holiday Inn, Toronto. Largest amateur radio convention in Canada. Includes Friday night eyeball buffet and dance, Saturday night banquet and dance, ladies' program, and many more social activities. Convention program includes Amateur Forum, Radio Propagation, Emergency Communications, Components, Flea Market, and much more. Registration before Sept. 30 non-member $8, member $7. Talk-in stations: 75 meters – ONTARS 3755 MHz Friday 1300-2300 hrs local time, Saturday 800-1400 hrs. Sunday 0900-1200 hrs. 2 meter FM – VE3RPT – 146.46/147.94. Simplex – 146.51. he convention call will be VE3RSO – be sure to check in!

MARION OH
OCT 24

The Marion Amateur Radio Club's "Heart of Ohio Ham Fiesta" will be held October 24, 1976, at the National Guard Armory, Marion, Ohio. Pre-registration – $1.00. Send SASE for tickets or info to Earl Adey WB8EDO, 2697 Curren Drive, Marion, Ohio 43302.

VIENNA VA
OCT 24

The AMRAD COMPUTERFEST will be held on October 24, 1976 at he Vienna Community Center, 120 Cherry St., Vienna, Virginia, near Exit 11S of the Washington, DC Beltway.

NEW ORLEANS LA
OCT 30-31

The New Orleans Hamfest and Computer Fest, sponsored by the efferson Amateur Radio Club, will be held Oct. 30-31 at Archbishop Rummel High School, 1901 Severn Ave., Metairie LA (New Orleans uburb). Forums at the fourth annual vent will include several on computers by the Crescent City Computer Club and others by or about AMSAT, MARS, emergency communications, RTTY, QRP, Novices and beginners nd antennas. Reservations and latest etails may be obtained by writing to Dominick "Nick" Tusa WA5RMC, Chairman, New Orleans Hamfest, PO Box 10111, Jefferson LA 70181. Talk-in frequencies will be 146.34-.94 and 3.95 MHz.

PLYMOUTH IN
OCT 31

The Marshall County Amateur Radio Club Swap-n-Shop will be held on Sunday, October 31, 1976, at the Plymouth, Indiana National Guard Armory located at 1220 W. Madison Street from 7 am to 4 pm. Free tables, no charge for set-up. Tickets $2 at door. Food, drink and door prizes. Talk-in on 146.07-67 and 146-94 simplex. For further information contact WA9INM, Route 3, Box 526, Plymouth, Indiana 46563.

McAFEE NJ
NOV 13-14

The 1976 Hudson Division Convention will be held November 13-14, 1976 at the Great Gorge Resort Hotel in McAfee, New Jersey. There will be ARRL and FCC forums, large indoor exhibit area with 40 booths, giant outdoor flea market, super raffle, free gifts, special features, indoor swimming, game room, and much more. Registration: advance $3, at door $4. For hotel registration: Al Piddington WA2FAK, 4 Acorn Drive, East Northport NY 11731.

The Coffee Flipper

--and executive decision maker

Twice a day, American industry grinds to a halt. Work stops as everyone leaves his bench or desk for a coffee break. It's the time when everybody relaxes, has a cup of coffee or other beverage and forgets work for a few minutes. Often, a small group will collect and flip coins to decide whose turn it is to buy.

But, hey! That's almost work itself. The whole idea of the coffee break is to cease one's labors and unwind. With this thought in mind, I set my creative juices flowing. Drawing upon my vast experience and unlimited talent, I cast about for some means of minimizing effort and s-t-r-e-t-c-h-i-n-g my coffee breaks by automating the coin toss.

Several methods floated by my mind's eye: How about a gated oscillator controlled by a push-button switch and feeding a flip flop? The two outputs of the flip flop could feed two lamps, one labelled "heads" and the other "tails." Pushing the button would turn on the oscillator which would start the flip flop going back and forth. If the rate was fast enough (10 Hz or so), it would be impossible to perceive the lamp states, so that when the button was released, heads or tails should come up randomly. Maybe for a multiple player version, I could use a shift register or ring counter somehow, so that only one light would come on at the end of the cycle, that corresponding to the lucky player who buys for the day.

Shucks! Pressing a button is almost as strenuous as flipping a coin, though. And using the ring counter could get complicated, not to mention the cries of "Foul!" since only one person would decide the fate of everybody playing. Then too, the gadget couldn't get too complicated 'cause I wanted to build it completely from my junk box.

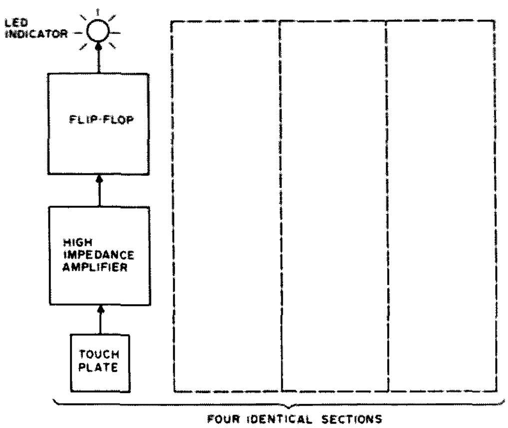

Fig. 1. Functional block diagram.

Description

A block diagram of the final product is shown in Fig. 1. Since usually three or four players participate, there are four sections, one for each. Operation is simple. A finger placed on a touchplate conducts 60 Hz hum (courtesy of radiation from the ac power line) to the high gain amplifier. The amplifier takes this low level sort of sine wave and squares it up, feeding steep-sided pulses to the flip flop. The flip flop controls the readout — one LED per

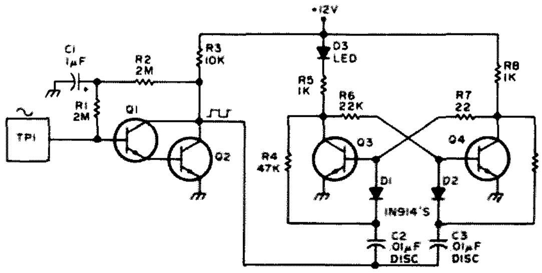

Fig. 2. Schematic diagram of "coin" block.

section. Simplicity and lack of effort are outstanding for this configuration. The touchplate control system exemplifies modern labor saving techniques similar to those used on the latest home appliances. Only one illuminated display element is required per stage, since one need not have heads or tails, just on and off. This saves the mental work of remembering heads and tails, plus it saves on parts – LEDs cost 20 cents apiece!

Refer to Fig. 2 for detailed operation. Touchplate TP1 is connected to the base of a Darlington pair composed of Q1 and Q2. R3 is the collector load, while R1 and R2 bias the pair in the active region. C1 bypasses ac feedback so that dc biasing is achieved with least effect on ac gain. The stage has a high input impedance and enough gain to "square up" sine waves impressed on the touchplate by a finger placed thereupon (remember checking a tube audio amplifier by putting a finger on the grid terminal?). The square waves are fed to a flip flop (a.k.a. bistable multivibrator), formed by Q3 and Q4. R5 and R8 are the load resistors, while R6 and R7 provide the cross-coupling required for flip flop operation. Gating diodes D1 and D2 are biased by resistors R4 and R9 so that incoming pulses are steered from C2 and C3 only to the stage which was conducting before the negative edge of the pulse occurs. This steering circuit assures reliable "toggling" of the flip flop so that it flips states only once for each incoming pulse. As mentioned earlier, there is only one readout per "coin" block. It can be connected in either load resistor leg to the positive supply voltage. In the circuit shown, the LED is connected to Q3 and R5 so that it lights when Q3 conducts.

It may appear that both the high impedance input amplifier and flip flop are slightly more complicated than necessary. Strictly speaking, this is so, if transistors of known types are used. However, this design can use darned near anything in the junk box.

Construction

The basic overall layout is shown in Fig. 3. The components were wired on a piece of vectorboard approximately 2.75" x 6.5". The four "coin" blocks were laid out so that the LED was placed closer to its corresponding touchplate than any other for ease of interpretation. Component to component wiring was done on the back side, with only the two power leads (+) and (-) brought out to Vector T-28 pins for external connection. To maximize cost effectiveness, no power supply was included. Any source of 9 to 15 volts at 40 mA will do. No cabinet was used both to save money and to impress everyone by having the "guts" showing. Since all signals are low frequency, wiring and layout are very non-critical.

As mentioned earlier, the circuit was designed so as to be intolerant to component variation. Values shown in the schematic were used because I "guesstimated" that they would work. If you use something else, it will probably work. To be on the safe side, use "symmetrical" parts substitution in the flip flop. For example, if you want to use a 27k at R6, be sure that you use the same resistance for R7. All transistors used were NPN silicons with squirrely "in-house" type numbers. If you want to buy new ones, MPS 5172 or 2N5172 types are fine. Actually any NPN silicon with an hfe of 50 or more and a breakdown voltage over 20 volts should work. The LED is a 5 for $1 type picked up at a hamfest. Since it runs at about 12 mA, almost anything will do. The touchplates used were about .5" x .5" pieces of thin copper attached to the vectorboard with bathtub caulk (Ge RTV). Naturally, they must be insulated from ground.

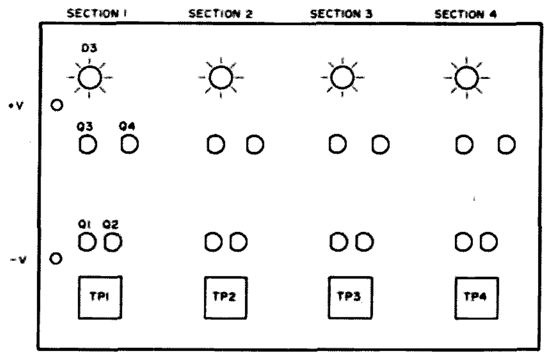

Fig. 3. Coffee flipper component layout.

Usage

The basic ground rules for using the flipper are like those for "matching pennies." For two people, both players place one finger on their individual touchplates. One says, "If they match – you buy" or "If they're alike, I buy." They count to three and at the count of three they remove their fingers from the plates and look at the two corresponding lights. For three or more players, you can play "odd-man-buys" or "odd-man-out." In the latter case, the odd man drops out and the remaining players continue. To be polite, we usually call the player who buys the "winner." After all, he wins the honor of buying!

Results

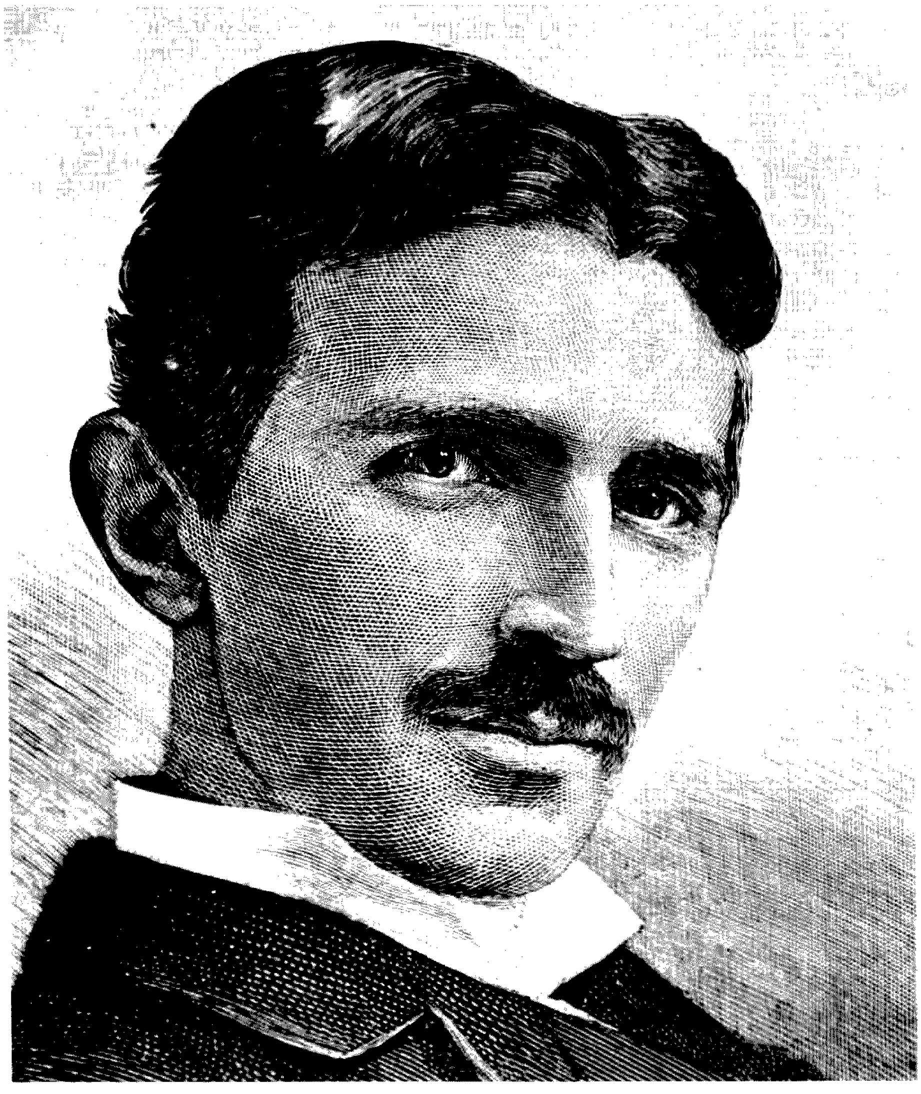
Some questions have been raised by frequent "winners" about the randomness of the results of my "coin." Even I wondered because I "won" the first six buys. Jim Shultz W3MYK said, "It's not gambling; with Joe playing it's a sure thing!" But several runs of 50 and 100 successive trials each have demonstrated an even distribution of results. You may buy six days in a row, but if you live long enough, the game is fair. The only signs of erratic operation have occurred in the presence of rf fields or near sources of electrical transients such as relays or electric motors.

Conclusion

Many hours of man-effort have been saved in using this device. The integrity of break time as a period of relaxation has been maintained. And, because even vending machine coffee tastes better when someone else buys, I must thank Jim Shultz, Vic Frey and Daryl Kane for countless gallons of that delicious brew! ■

The Man Who Invented AC

-- Tesla, the greatest pioneer of them all!



Nikola Tesla (1856–1943), the inventor whose discoveries completely changed the cadence of human progress, spent his entire life under the influence of an irresistible impulse for crossing frontiers and delving into the unknown.

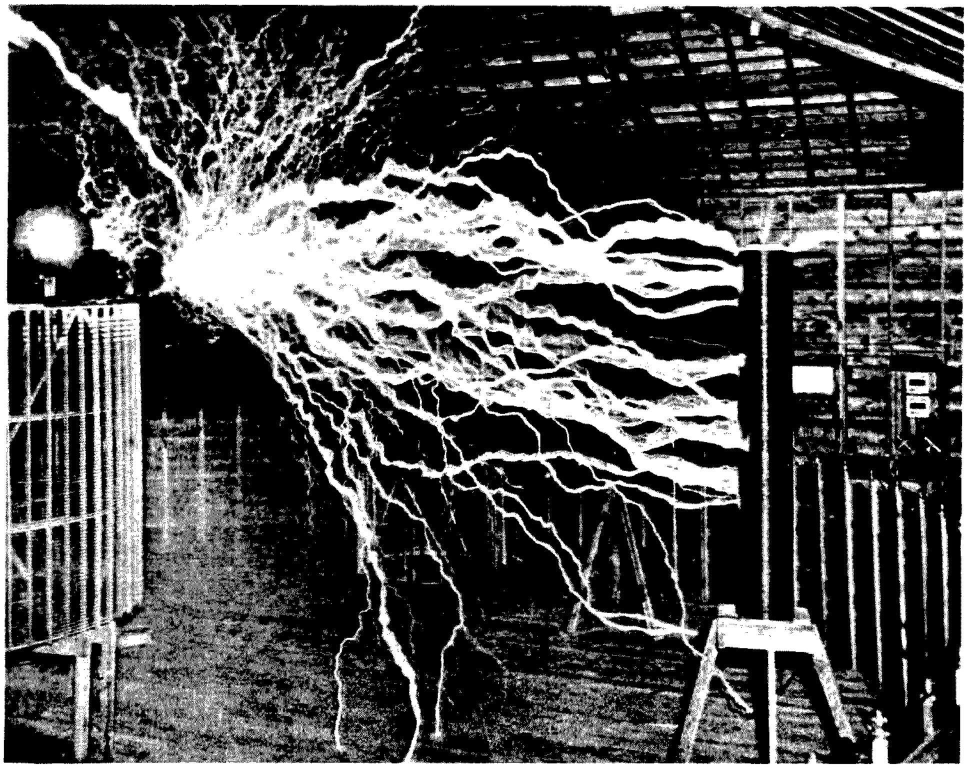
Harry Goldman
34 Amy Lane
Glens Falls NY 12801

A young immigrant from Yugoslavia stirred the world of electrical engineering when, in 1888, he presented a paper, "A New System of Alternate Current Motors and Transformers," before the American Institute of Electrical Engineers (N.Y.). His discovery of the rotating magnetic field and its application to the generation, transmission and utilization of polyphase alternating currents for power and light brought electrification to the world. Every high-tension tower and transmission line bisecting the world's countrysides are lasting monuments to Nikola Tesla's genius. Not widely remembered, however, are his contributions to the establishment of early radio communications and broadcasting.

In 1889, the inventor commenced a series of investigations into the properties of high-frequency alternating currents. Except for his earlier work in low frequency ac and an occasional venture into incidental fields, high-frequency researches were to remain the dominant objective of his inventive career. Originally, it was his

ambition to utilize these currents in developing a more efficient system of lighting. Shortly thereafter, Tesla inaugurated experiments which were to place him on a trail leading to communications, a goal which eventually evolved into an obsession.

Although it is not clear what force motivated Tesla in this direction, his intense interest in radio was probably initiated as a result of Heinrich Hertz's experimental work. Finding inspiration in James Clerk Maxwell's electromagnetic wave theory, Hertz was able to transmit, receive and measure radio waves. It is without question that Maxwell's mathematical treatise, "Electricity and Magnetism," initially announced in 1864, and Hertz's "Electromagnetic Waves in Air and Their Reflections," published in 1888, formed the genesis of radio engineering.



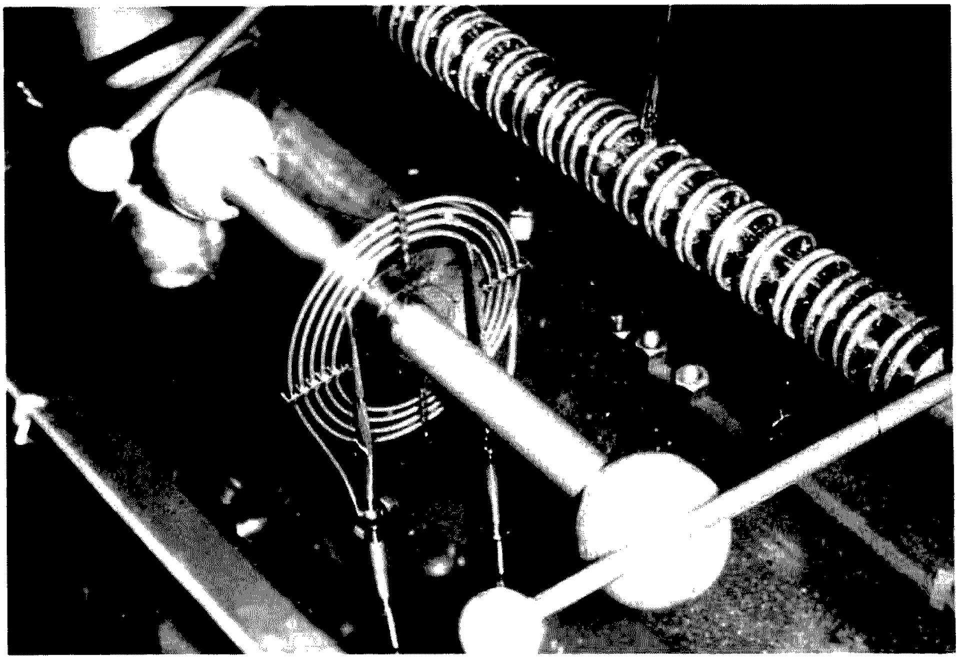
The Magnifying Transformer, the heart of Tesla's high voltage experiment for producing an immense resonant action. The cascading discharges shown here measure 22 feet and represent a potential of 12 million volts. (The Century Magazine, *June 1900)*

Although Tesla was among the earliest who foresaw the application of electromagnetic waves in point-to-point communications, he continuously contested the concept of radio transmission by Hertzian waves. He attributed communications between ground stations to earth conduction. Later, when challenged to explain transmissions between ground stations and airplanes, the inventor responded, "capacitor action." Tesla rarely wavered in this debate and it is probable that his persistent inflexibility retarded, if not prevented, proper recognition for his contributions.

By 1890, he had constructed alternators capable of producing undamped waves at 30 kHz. Some twenty years later, the radio industry, then beginning its embryonic stage, found undamped waves highly desirable. As a result, the high-frequency alternator became a sophisticated piece of equipment, holding a position of great significance in radio transmissions until the advent of the high-power triode in 1922. As a striking example of its import, it was possession of the Alexanderson alternator patents which gave RCA a nearly insuperable advantage in early global communications. Thus, Tesla's conception of employing continuous waves, and his design of apparatus for producing them, preceded the radio industry by at least two decades.

Tesla again aroused the attention of the scientific world in 1891 when he presented the first of a series of historic lectures revealing discoveries from experiments with radio frequencies.(1) Among these was the disclosure of a new kind of transformer. Better known as a "Tesla" coil, this device represented the first application of the oscillation transformer. The Tesla transformer provided a remarkable advancement in that it invoked the principle of inductively coupled tuned circuits. Consequently, in his initial approach to communications, Tesla stumbled upon another important facet, the principle of tuning. Time has not dimmed its importance.

One gains an insight into the inventor's experimental wisdom and prophetic vision through reference to a sensitive emission within his vacuum tubes. In the lecture of 1892, given before the Institution of Electrical Engineers in London, Tesla states, "I think that it may find practical applications in (wireless) telegraphy. With such a brush, it would be possible to send dispatches across the Atlantic with any speed . . ."(2) The advanced state of our present technology may blind us from sensing the impact of the inventor's declaration. At the time, several leading figures of the scientific world conceded the impossibility of traversing the Atlantic's prohibiting span with an electromagnetic wave. To Tesla, the Earth's magnitude was of little consequence. ". . . I would say a few words on a subject which constantly fills my thoughts and which concerns the welfare of all. I mean the transmission of intelligible signals or perhaps even power to any distance without the use of wires . . . we need not be frightened by the idea of distance. To the weary wanderer counting the mileposts, the Earth may appear very large; but to the happiest of all men, the astronomer, who gazes at the heavens, and by their standard judges the magnitude of our globe, it appears very small . . and so I think it must seem to the electrician . . . it certainly is possible . . . to produce some electrical disturbance



A 5 million volt Tesla coil developed for nuclear physics research in 1929 by G. Breit, M.A. Tuve, and O. Dahl. The multi-sectioned vacuum tube at the upper right was used to accelerate atomic particles. (Photo courtesy of T. Brown, Dept. of Terrestrial Magnetism, Carnegie Institution of Washington)

sufficiently powerful to be perceptible by suitable instruments at any point of the Earth's surface." (3)

In his final lecture of the "trio-series," Tesla suggested a system of radio communications employing synchronized aerial-ground elements at the transmitting and receiving stations.(4) In view of this disclosure, it would seem that he was the first to conceive the idea of using transmitting and receiving antennas tuned to the same frequency. Therefore, by 1893, some four years before contemporaries had made equally significant contributions to the art, it appeared that Tesla possessed both the technology and ambition as well as the visionary powers necessary for bringing radio communications to its fruition. What impediment barred him from achieving the honor?

On March 13, 1895, Tesla experienced a serious setback. The entire contents of an inventive career, as well as records, documents and a world's fair exhibit were lost when a fire destroyed his New York City experimental station. Undoubtedly, the tragedy barred Tesla from establishing priority in several fields. His position in the world of science was evaluated by an article in the *New York Sun*. "The destruction of Nikola Tesla's workshop with its wonderful contents is something more than a private calamity. It is a misfortune to the whole world. It is not in any degree an exaggeration to say that the men living at this time who are more important to the human race than this young gentleman can be counted on the fingers of one hand – perhaps on the thumb of one hand."(5)

Tesla opened a new laboratory. By 1897, he had carried out investigations in the field of x-ray, studies of the dynamics of mechanical vibrations, the invention of electromechanical isosynchronous alternating-current generators as well as experiments with radio-controlled devices. One of his important contributions of this period was a high-frequency patent containing the fundamental principles upon which the "four-tuned-circuit system" of radio transmission was to be founded.(6) Professor Adolph Slaby, Germany's leading authority in early communications, demonstrated an enthusiastic appreciation for Tesla's work. In declaring Tesla as the "Father of Wireless," he wrote, "I have been engaged for some time in investigations in telegraphy without wires, which you have first announced in such a clear and precise manner in your 'inventions.' It will interest you as the father of this telegraphy . . ."(7)

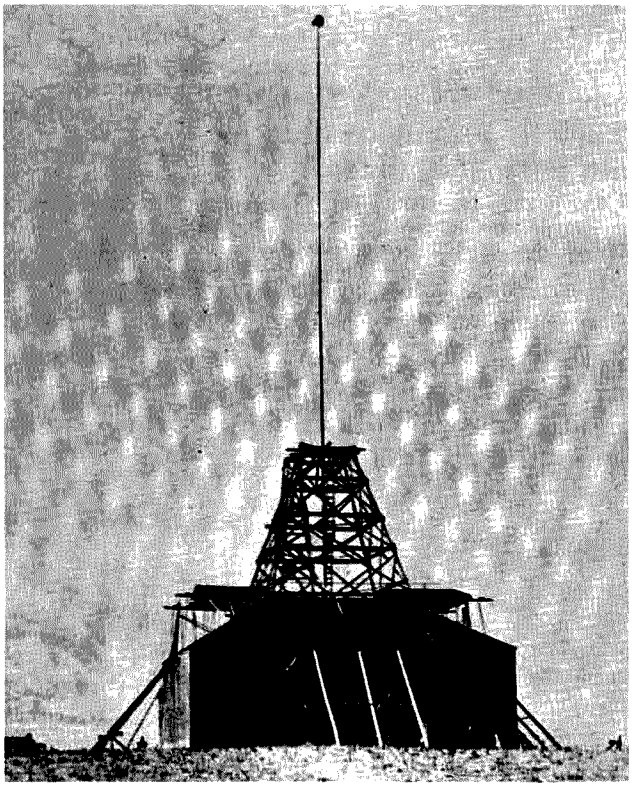
Restricted by the limits of his New York laboratory, Tesla left for Colorado Springs in 1899 to initiate experiments on a large scale. Communications was to be but one phase of his project. Another was the transmission of electricity without the use of power lines. He was of the conviction that resonant effects of huge magnitude would enable him to utilize the Earth as a conductor. "Not only was it practicable to send telegraphic messages to any distance without wires," stated Tesla, ". . . but also to impress upon the entire globe the faint modulations of the human voice; far more still, to transmit power in unlimited amounts to any terrestrial distance and almost without loss."(8)

There, in the shadows of Pike's Peak, he constructed a large barn-like laboratory. Extending through the roof was a 200-foot mast topped by a 3-foot copper ball. Within the mysterious construction was an array of apparatus reminiscent of a Jules Verne fantasy. It was Tesla's intention to employ the equipment in an attempt to alter the electrical charge of the Earth.

The concrete achievements of the Colorado adventure remain obscure. Except for a lecture, some scattered notes, and a few ambiguous articles, he never fully disclosed the outcome of the experiment. He announced the discovery of standing waves induced in the Earth's static charge by nature's lightning and was able to duplicate them by bringing about an immense resonant action. In an experiment which has not since been equaled, Tesla produced the longest point-to-point man-made lightning discharges (135 feet) with an absolute potential of 18 million volts and antenna currents of 1,100 Amperes. This, and his ability to operate Earth-connected motors and electric lamps at a distance of eighteen miles from the source of energy, must be recorded as remarkable feats of engineering.

Tesla demonstrated the vision of a true prophet when he suggested the employment of standing waves as a means for detecting the position and movement of distant objects. "... By their use ... we may determine the relative position or course of a moving object such as a vessel at sea ..."(9) It wasn't until just before World War II that radar, as foretold by Tesla, became a working reality.

Upon his return to New York in 1900, Tesla began construction of a transmitting plant on Long Island. Residents of early Shoreham can recall the gigantic tower situated on a tract of land known as Wardenclyffe. The station was to be but one of a series of components making up Tesla's "World System" of broadcasting. In addition to the distribution of news, music and humanity services provided by today's communications media, the inventor promised a number of startling benefits. It was to establish a universal system of telephone, telegraph and stock ticker services; a precision clock system whereby all the world's timepieces would be accurately synchronized from a master station; a safe system of navigation enabling control of direction without compasses and an ability to determine exact location, hour and speed at a moment's notice. Also, it was to provide a world system of private communications allowing personal telephone connections between parties, regardless of distance, with a device small enough to be carried in one's pocket.



An external view of Tesla's mysterious experimental laboratory at Colorado Springs. Erected in 1899, the inventor undertook experiments to alter the electrical charge of the Earth. He produced discharges that rivaled nature's lightning bolts and revealed the presence of standing waves in the Earth. (The Electrical World and Engineer, *March 5, 1904)*

The Long Island plant was never completed. The cost of the project exceeded the inventor's available funds. The greater part of Tesla's endeavors were financed by private sources. John Jacob Astor, J. P. Morgan and Thomas Fortune Ryan can be cited as the most influential of Tesla's creditors. In addition, a demonstration of the feasibility of the "World System" principle was hampered by the complexity of a recurring illness. The tower remained intact for many years. Shrouded in an atmosphere of mystery, it proved to be but a landmark in evidence of the bold dreamer who had passed that way. The late John J. O'Neill, *New York Herald-Tribune* Science Editor, provided a description of its demise in his biography *Prodigal Genius, The Life of Nikola Tesla.* "... Heavy charges of dynamite were necessary in order to topple it, and even then it remained intact on the ground like a fallen Martian out of Wells' *War of the Worlds.*"

In an objective which no other person had then dreamed possible, Tesla had visualized, and nearly created, broadcasting some twenty years preceding its eventuality. "Of course," stated Edwin H. Armstrong, radio pioneer and inventor of FM, "the instrumentalities for practicing broadcasting were not then in existence. Tesla was classed as a visionary and his prophecy was forgotten. What harsher terms might, with justice, be applied to many of us who helped produce the instrumentalities with which broadcasting was eventually accomplished! We applied them to point-to-point communications, failing completely to realize the significance of Tesla's words."(10)

In addition to the major goals mentioned herein, Tesla made an infinite variety of contributions to communications that remain generally unknown. The most striking example is a patent describing an invention for controlling moving objects by radio waves.(11) With this invention, Tesla singularly ushered in the age of radio-guidance systems. "We shall be able ... to send a projectile at a much greater distance; it will not be limited in any way, weight or amount of explosive charge; we shall be able to submerge it at command, to arrest it in its flight and call it back, and to send it out again and explode it at will; and more than this, it will never make a miss ..."(12) Spectacular demonstrations of his radio-controlled device were presented in a week-long display at Madison Square Garden (N.Y.) and again, later, in Chicago. But to Tesla, this was just the beginning. In a gesture true of his unlimited imaginative powers, he proposed radio-controlled robots capable of thinking for themselves. He coined them *automatons.* "... It will be able to follow a course laid out or to obey orders given far in advance; it will be capable of distinguishing between what it ought and what it ought not to do ..."(13) Tesla's utterances raised more than the eyebrow of the scientific world. Resulting protests surpassed the discontent of indignation. The significance of Tesla's words, however, becomes more apparent when we consider today's vast industry of self-thinking machines as well as the huge arsenal of radio-guidance missiles poised at their stations throughout the world. These devices are able to perform exactly as Tesla had predicted.

Among his incidental contributions to radio communications was the Tesla "ticker," a device for

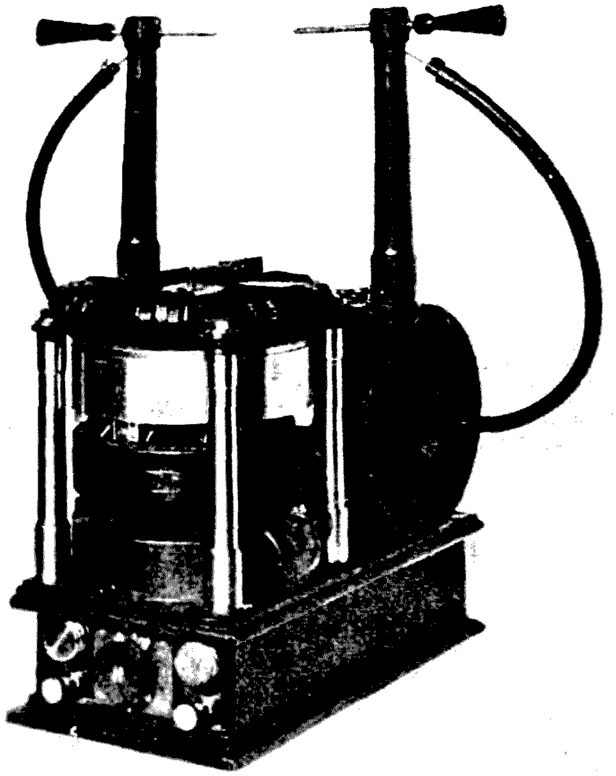
making continuous waves audible. This apparatus was a vital part of the Paulsen Arc stations until the heterodyne beat-note system was introduced to radio engineering. Several forms of Tesla's high-frequency spark apparatus were utilized by early transmitting stations for many years. His radio patents advanced the quarter-wave principle as well as antennas in the form of a loop. And it was Tesla who pointed out the importance of oil as an insulating medium in high-voltage equipment and who suggested the use of insulated stranded wire, later called Litzendraht, in high-frequency circuits.

Taking into consideration all that has been mentioned in the foregoing, why then is the name of Nikola Tesla not listed among the journals of radio engineering history? Several explanations are possible. For one, Tesla was a complex personality. "He was a strange figure in the rough-and-tumble field of pioneer wireless and electricity," wrote one who met Tesla. "Many considered him a plain snob. Some called him a nut while others referred to him as the 'genius' and were always making excuses for his actions ..."(14) Hampered by a grand-gesture personality and driven by an extraordinary ingenuity, his talents remained eternally subservient to a passionate and inexorable urge for stirring deep waters. Consequently, his mental capacities continually outraced his physical ability for bringing original ideas to a real existence. His pattern appears to have been to discover, and then move onwards leaving for others the benefits of its commercial application. And in his experimental processes, he was forever being diverted from the path of his major goals (as is evident by the variety of his inventive accomplishments) delaying, if not preventing, final achievement of his original destinations.

There should be little doubt concerning the inventor's faculties for establishing a communications system. Its reality, however, proved to be too great a task, both physically and economically, for the efforts of an individual. Had he been associated with talent similar to the likes of a David Sarnoff, that energetic personality who brought the "music box" (radio) into every home and who led the Radio Corporation of America to communications history, his objective might have been assured.

Fritz Lowenstein, an assistant in his high-voltage experiment, and who later produced some excellent work in radio communications, if given a chance, might have served Tesla to great advantage. Lee De Forest, an inventor whose contributions are well established in the glorious history of radio, pleaded to be taken in as a Tesla assistant. Without detracting from their brilliant work, it is known that the many successes of men such as Edison and Marconi resulted from their ability to attract the assistance of highly capable associates. Tesla, however, was unable by temperament to avail himself of this advantage. Essentially, he was a "loner" who stood aloof and out of reach of those with whom he mingled.

On December 12, 1901, while Tesla was constructing his 300,000 Watt Long Island broadcasting station, Guglielmo Marconi, with but a fraction of that power, scooped the scientific world by sending three dots from Poldhu, England, to Saint John's, Newfoundland. The scientific society hailed Marconi. Even Tesla sent a congratulatory note but it was quite evident that he had



An early Tesla coil, the only invention of his many contributions which still bears his name. Tesla used devices such as these to carry out researches with high frequency alternating current. His discoveries hastened the development of ac induction heating, diathermy, neon and fluorescent lighting, x-ray equipment and techniques, and radio guidance systems, as well as television and radio communications. (Electrical Experimenter, *July 1919, by permission of Hugo Gernsback*)

been struck a blow by Marconi's feat. A crushing defeat to Tesla's bid for radio immortality came about in 1915 when he battled Marconi over the fundamental issues upon which early radio had become established. The courts ruled against Tesla, a judgment which was to influence succeeding litigation as well as to provide Marconi the means with which to institute unmitigated assertions for the invention of radio.

In his book, *Marconi*, Orrin E. Dunlap, Jr., provides an interesting comment. "At the turn of the century it was remarked that it was difficult to invent anything basically new in radio, and still more difficult to invent anything which did not have some bearing on or had not been preceded by an invention of Nikola Tesla. In 1891, at Columbia University, Tesla demonstrated the principle of tuning. He obtained patents on tuned circuits and claimed more than 100 tuning inventions. Nevertheless, it is called Marconi wireless; not Tesla wireless."

Be all that as it may, Tesla's part in the evolution of communications was not to be denied completely. In the October sessions of 1942 and 1943, the Supreme Court declared the Marconi "four-tuned-circuit" patent, his most vital contribution, invalid because of prior disclosure by Tesla, Stone and Lodge.(15)

In summation, we find in

Nikola Tesla a personality possessing an experimental acuity and prophetic vision equaled by no more than a handful of colleagues and surpassed by none. That he contributed to the groundwork of radio communications is evident through an examination of his lectures, articles and inventions pertaining to the subject. Although once hailed as "Our Foremost Electrician . . . Greater Even Than Edison," Tesla's accomplishments have since faded from the indexes of printed matter.(16) Consequently, it is possible – though not probable – for an engineering student to complete a formal education without having heard of Tesla.

In an evaluation of the inventor's contributions to radio engineering, L. P. Wheeler credits Tesla with the independent discovery of the principle of inductive coupling between the driving and working circuits, the importance of tuning both circuits, that is, the idea of an oscillation transformer, and the employment of the capacitance loaded open secondary circuit. He describes Tesla as "... an immensely energetic personality possessing great skill in ac techniques and great ingenuity in their utilization ... his earlier accomplishments . . . together with the inspiration given to many through his public lectures, would seem to justify a place in the history of radio engineering not so very far below that due to his accomplishments in the field of low-frequency alternating currents." Baudot to ASCII

-- you want to learn programming?

Mark J. Borgerson
325 N.W. 9th, #3
Corvallis OR 97330

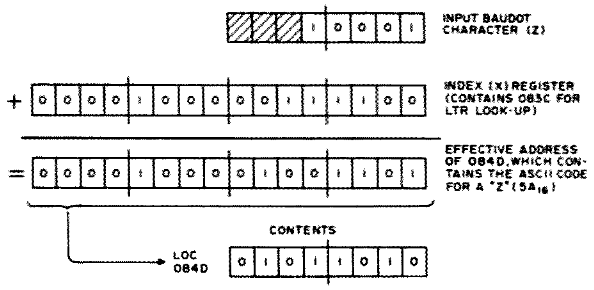

Fig. 1. Example of generating the effective (final) address to the correct ASCII code by adding the input Baudot code with the contents of the Index Register.

One of the most enlightening (but little used) methods for learning programming techniques is to read someone else's programs. Therefore, let us suggest you look over this article even if you aren't interested in Baudot to ASCII conversion. And if the symbolic coding in the listing seems to be a problem, don't let it be — simply analyze the machine language code. — Ed.

This program is used to convert 5-bit Baudot code from a parallel input into ASCII characters and display those characters. The program is written to run in a Southwest Technical Products 6800 microcomputer with a parallel interface located at memory location 8016 (hexadecimal notation). The program uses the output subroutine OUTEE, which is resident in the system's MIKBUG® operating system. Total program length, including the lookup table, is 123_{10} bytes. Because of the indexed lookup routine used, the routine is not suitable for permanent storage in ROM. The program may be located anywhere in memory space if the references to location LTRLOC and FIGLOC are changed to agree with the new locations.

The program operates by reading the parallel input port (after appropriate initialization) and looping until bit 7 goes high, indicating a character is present in bits 0-4. Bits 5-7 are masked out and the resultant 5-bit pattern is stored in location LOOKUP+1 where it becomes the displacement added to the index register. The index register contains either a pointer to the FIGURES or the LETTERS lookup table, depending upon which of

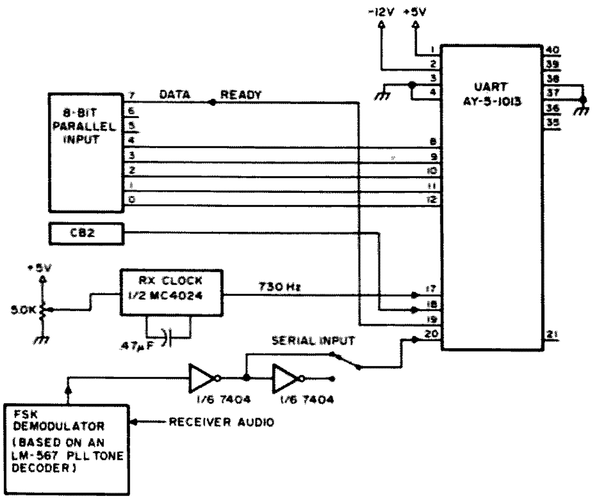

Fig. 2. Baudot to ASCII Conversion hardware configuration. Notes: CB2 is a handshake control output from the PIA. This output is under program control and is used to reset the UART after the word is read. Resetting the UART drives the DATA READY line low until the next complete data word is available.

Table 1. Baudot to ASCII Lookup Table. Note: The locations corresponding to LTRS and FIGS contain NULLS (00) since these functions are taken care of outside the lookup table. The location for BELL is also a NULL since my terminal does not have this function.

these control characters was last received. The program automatically loads the location of the FIGURES table upon startup.

After the Baudot character has been read and stored, the reset subroutine outputs a short positive pulse to the UART used to convert the serial Baudot characters to parallel form. This pulse clears the UART parallel output register and readies it for the next word. The reset pulse is output via the CB2 control output of the parallel interface.

When the Baudot character has been stored as the index displacement, the appropriate ASCII character is fetched from the lookup table (using this index) and read into accumulator A (see Fig. 1). The program then outputs the character via the OUTEE subroutine to the computer control terminal (a CT-1024 TVT in my case). The program then branches back to the input step to wait for the next character.

The program does not incorporate an automatic "unshift on space or CR," so a missed LTRS command will result in a continued string of figures. This can be overcome by storing the program starting location at memory locations A006 and A007$_{16}$. These are the non-maskable interrupt vector locations. A push-button to ground on the computer's NMI line will cause the program to restart, automatically shifting to the LTRS lookup table. ■

Baudot and BASIC

-- an interpreter for a Baudot computer

In previous articles of this series, we have attempted to demonstrate that Baudot teletype equipment can perform the input/output function in a hobby computer system. In the first article, a simple and inexpensive interface to bring a Baudot Model 19 on-line with an Intel 8080-based computer was described. The second article concerned the use of Baudot paper tape equipment for storage of data. In the third article, a system program called the Baudot Monitor/Editor (BM/E, for short) was presented. BM/E made it possible to enter, modify, and execute machine language programs via the Baudot printer/keyboard. Throughout, we have tried to keep hardware requirements to a minimum and thus encourage readers to get their old Baudot equipment up and running. As a further inducement along this line, we now present a high level language software system for use with Baudot equipment, but before we get the cart before the horse, perhaps we should back up and discuss computers and high level languages in general terms.

What is a High Level Language?

Computers are sometimes referred to as "thinking machines." In actual fact, the "thinking" is done by a human long before the computer is put to work. The computer merely performs a logical sequence of well-defined operations that are predetermined to achieve the desired results. On the lowest level, these operations consist simply of the computer's machine language instruction set. Working at this level requires an understanding of binary arithmetic, data encoding, I/O handling, memory allocation, and a number of other machine-related concepts. For those who do not have this specialized knowledge, or who simply want to avoid the intricacies of working at the machine level, a different approach is needed. Over the years, many efforts have been made to develop machine language programs to help humans achieve better working compatibility with computers. We might think of these programs as providing a computer/human interface. In most such software systems, decimal arithmetic is implemented to avoid the difficulties associated with machine level binary. In addition, ordinary words and alphabetic symbolism are adopted for use in directing

the computer's operation. This relieves the need for using the machine's purely numerical instruction code. The authors of these software systems (through their choice of the words and symbolisms) created what is referred to as a high level language.

Many different languages of this type have been developed to meet the needs of different potential users. FORTRAN, with its mathematical orientation, has become the principal language for scientists and engineers. Another high level language, COBOL, has achieved stature in the business world because of its good file management capabilities. Still another language which has gained wide use is BASIC. As the name implies, BASIC was intended for people just getting started in computers. Its simple and convenient operational features make it a natural "learner's language." It would take pages to recount all of the high level languages that are in use — or have faded from the scene. But it's important to note that the existence of these software systems has done much to further the wide acceptance and use of computers.

Why Learn a High Level Language?

Although there are perhaps dozens of good reasons for learning a high level language, most derive from this one fact: High level languages are people-oriented, while low level languages are machine-oriented. People are far better able to utilize the capabilities of the computer if they are not burdened by the details of machine level operation. In addition, high level languages are not machine-dependent, as are low level languages. For instance, suppose you learn BASIC on a Data General Nova and then wish to use another machine like the Altair 8800. No problem. BASIC is fairly well standardized from machine to machine. Of course, on the machine level, the Nova and Altair are vastly different. But on your side of the software interface, both systems appear the same. Learning a high level language like BASIC will greatly extend the usefulness of your computer, and at the same time broaden your future capabilities!

What is a BASIC Program?

Humans perform tasks very often without clearly recognizing the steps involved. Computers, on the other hand, cannot perform even the simplest task without having the steps precisely set out beforehand. It is this fundamental weakness of present-day computers that make them need us! We call this step description process "programming." Contrary to what you might think, programming in a high level language does not require a massive learning effort on your part. A reasonably competent sixth grader will have already acquired the knowledge required to understand what a computer does. The problem simply reduces to learning how to make the computer do it! This is where BASIC comes in. BASIC consists simply of a group of commands or instructions that you arrange in a particular order to perform the required task. To become a

good programmer, you must think through a task a step at a time, recognizing at each which BASIC command should be used to accomplish it. If you are unaccustomed to this type of problem-solving, you may find it difficult at first. However, as time goes on, you will no doubt find this careful point-by-point analysis of a given task a very satisfactory approach to problem-solving, both on and off the computer.

Where To Get the Basics of BASIC

People have written entire books describing the BASIC language. It would hardly be possible to adequately reduce such volumes to one or two paragraphs. The best we can do here is to list the names of some books that will provide detailed discussion. Table 1 includes a list of recommended books and their possible sources. For the real greenhorn, we highly recommend the small book entitled, *My Computer Likes Me When I Speak BASIC.* From this you can gradually work up to some of the more comprehensive books.

In addition to a book, you will need a BASIC operating system for your computer. That's where TINY BASIC EXTENDED comes in!

The TINY BASIC Project

In mid-1975, a project was started in the pages of *People's Computer Company* (PCC) *Magazine* to foster the creation of a small BASIC software system for hobby computers. The term "TINY BASIC" was coined for the system. The project culminated in the creation of a new software journal profusely entitled, *Dr. Dobb's Journal of Computer Calisthenics & Orthodontia.* Credit is due here to Bob Albrecht and others on his staff for encouraging the development of TINY BASIC and providing for its availability to hobbyists. We wrote the first version of TINY BASIC, and a complete description of the ASCII version appears in Volume 1, Numbers 1 and 2, of *Dr. Dobb's Journal.* Because our version had some features not included in the original design, we termed it TINY BASIC EXTENDED, or TBX for short. A Baudot version of TBX was also developed, and its description

Table 2. TBX instruction set.

follows in the remaining sections of this article.

A General Description

TBX is a small BASIC interpreter for use on an Intel 8080-based hobbyist system. It occupies the lower 3.2K of memory, so that one 4K memory board provides enough room for TBX and a BASIC program. The BASIC program is stored by line number in source form, i.e., the BASIC text is stored directly in Baudot. When the program executes, TBX scans the lines in numeric order and interprets the Baudot code. By "interpret," we simply mean that the computer determines which instruction is represented by the stored Baudot character string and then proceeds to carry it out. Fig. 1 shows how a line of TBX is stored. Further discussion of how TBX works can be found in Volume 1, Numbers 1 and 2, of *Dr. Dobb's Journal.*

Table 2 summarizes the instruction set available with TBX. An example is given with each, to help you see how the instruction is used. If a TBX instruction follows a line number, it will be entered into memory for later execution as part of the overall program. An instruction entered without a line number is executed directly. You may want to use this direct mode to become familiar with the TBX instruction set. Note that all arithmetic is integer and modulo 2^{15}, which means numbers cannot exceed ±32,767. This may seem like a limitation, but you will be surprised at the tremendous variety of programs that can be written within the framework of integer arithmetic.

TBX – The Baudot Version

The use of Baudot poses a few problems which must be overcome before a system like TBX can be implemented. As we mentioned in an earlier article, the Baudot machine uses a mechanical flip flop to change case. This means that the Baudot code for upper and lower case characters is the same; the physical position of the typing basket determines which will be printed. This mode of operation is unsatisfactory for high level language application, because it would lead to a code ambiguity within the computer. To overcome this difficulty, it is necessary to use an additional bit to indicate the case of the teletype. This produces the so-called 6 level Baudot code. Our May, 1976, article included a table of this code. The computer is given the task of keeping up with the case and seeing that the proper code is set internally. The TBX user merely enters the characters on the keyboard using the FGS and LTR keys as required. The computer does the rest!

Another problem arises because of the limited character set available in Baudot. A standard Baudot keyboard does not include the important symbols like "-", "+", and "*", among others. Some allowance has to be made for this if TBX is to be useful for calculation purposes. Table 3 shows the equivalences accepted by TBX for the missing symbols. Where there is a possibility of ambiguity, the computer understands which symbol is meant by content.

Conventional Symbol		TBX
=	(Equal)	: (Colon)
<	(Less Than)	((Open Parenthesis)
>	(Greater Than)	) (Closed Parenthesis)
+	(Plus)	& (Ampersand)
*	(Asterisk: Multiplication)	# (Pound)
-	(Minus Sign – Subtraction and Negation)	Same
/	(Slash Sign – Division)	Same
$	(Dollar Sign – Strings)	$ (Same – Line Statement Separator)

Table 3. Baudot symbol equivalences.

TBX – An Operational Description

In line oriented language like BASIC, programs are stored as a collection of num-

bered lines and then executed in numerical order. One of the great features of BASIC (and TBX, too) is the convenient method of line entry and editing. A line is entered by simply typing the line number followed by the line text and a Carriage Return (CR). The line is placed numerically in the proper position with lines already in memory. You can enter lines in any order, but they will always be stored, and later executed, consecutively by line number. If a line is entered with the same line number as one already in memory, the previous line is deleted before the new line is stored. To delete a line entirely, you enter the line number, followed immediately by a CR. In writing programs, line numbers are generally chosen in increments of 5 or 10 so that later additional lines can be inserted as necessary.

In TBX, a colon is used as a system prompt. This helps keep you posted on the status of the system. To use the direct mode, simply enter the instruction immediately following the prompt. NEW, LST, SZE, and RUN instructions are generally used in the direct mode, rather than as part of a program. If a number is entered after the prompt, TBX assumes you want to enter or delete a line from storage — no execution takes place, as in direct mode.

One of the features of a high level language like TBX is that it is able to detect programming errors and take action to prevent the system from destroying itself. To assist in debugging, TBX will print an error message. The message takes the following form:

ERR A B

A is the error code (see Table 4) and B is the line number at which the error occurred. If B is 0000, the error occurred during a direct mode instruction.

How To Obtain TBX

Because of the length of TBX code, an octal listing in this article is not feasible. A complete octal listing with instructions can be obtained for $5.00. Both a cassette and Baudot paper tape are available for $15.00 postpaid. Please specify Suding cassette, Kansas City Standard cassette, or Baudot paper tape (binary encoded). Address all inquiries or orders to: TBX Tape — Baudot Version, 305 Clemson Dr., Tyler TX 75701.

Sample Program

To help you get started, we have included the listing of a program written in TBX. A few lines of execution follow the listing. Studying this program will help you get started in BASIC programming.

Just think about it! Who would ever suppose that an old Model 19 could speak BASIC? Well, it can, and so can yours! ■

1	Input line too long — exceeds 72 characters
2	Numeric overflow on input
3	Illegal character detected during execution
4	No ending quotation mark in PR literal
5	Arithmetic expression too complex
6	Illegal arithmetic expression
7	Label does not exist
8	Division by zero not permitted
9	Subroutine nestling too deep
10	RET executed with no prior GOSUB
11	Illegal variable
12	Unrecognizable statement or command
13	Error in use of parenthesis
14	Memory depletion

Table 4. Error codes.

I/O REPORT

from page 132

address line. For example, locations ØE5A, B, and C contain a JUMP (4C) to location ØF4Ø. . . and with only the nine address lines used this will actually work out to be location 14Ø. The ØF4Ø is necessary, though, because address bit 11 is the enable for the PROM.

Toward a More Perfect Touchtone Decoder

-- Ma's system can be made to work well

Bell labs really started something with their DTMF (Dual Tone Multi-Frequency) dialing system.[1,2,3] Developed for easy rapid dialing and bearing the fancy name "Touchtone"* it rapidly outgrew its original purpose as developed for the Bell System. Touchtone signaling is widely used now anywhere a voice-frequency communications link is available. It offers a rapid, inexpensive means of sending non-vocal information using small inexpensive encoding devices (Touchtone pads) and requiring relatively simple, cheap decoders. Commercial uses include bank account status reporting, computer input/output, remote control and selective calling on radio systems. And, as any FMer knows, Touchtone signaling is widely used by radio amateurs for repeater control functions, selective calling and autopatches.

Touchtone usage by hams saw only limited usage so long as the only decoders available were surplus (?) Ma Bell or expensive commercial types. Signetics then simplified the whole matter when they introduced their 567 phase locked loop (PLL) tone decoder IC. Using the 567 makes building a tone signaling system very easy. Of course, the semiconductor industry recognizes a winner very quickly, so now the 567 type chip is available from National Semiconductor, Exar, and others, as well as from Signetics. This competition has decreased prices drastically, so that now you can find these chips available through *73 Magazine* advertisers for as little as $1.50 apiece.

Now that all that introductory stuff is over, let me tell you what this article is about. In the course of working with PLL ICs to make practical Touchtone decoders, I've found some useful methods and suggestions. I don't mean to deride the semiconductor industry's applications staffs, but their general overall treatment of applications data is too general to be fully workable. It's very frustrating to find that applications info stops just short of giving me enough detail to make a fully working circuit. The first trial usually works after a fashion, but the "bugs" have to be worked out. My intent in writing is to fill the information gap and my work may help others in using PLL decoders, primarily over radio transmission links as used by radio amateurs.

Tone Decoder Block

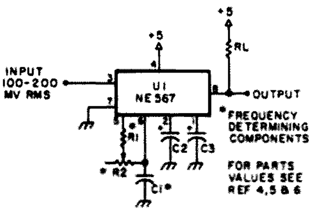
The basic PLL tone decoder building block is shown in Fig. 1(a). I won't give any detail about its inner workings or component values, since this information is well covered in several places.[4,5,6] The references also provide slightly differing circuitry, but the basic function remains the same. From now on, this decoder block will be shown as in Fig. 1(b). Basically, all the block does is provide a specific response to a predetermined range of frequencies. The 567 has an open-collector output which switches from a high resistance to ground to a low resistance state when the proper tone is applied to its input. Thus when the tone appears, current will flow through the load resistor R_L shown in Fig. 1(a).

In order to successfully decode a Touchtone signal, more than one such decoder block is needed. Each individual Touchtone symbol is transmitted as a pair of tones as shown in Fig. 2; for example, the digit "1" consists of a 697 Hz tone and one at 1209 Hz sent simultaneously. As you can see, these tones are arranged in two sets. The sets are called the high group (1209, 1336, 1477 and 1633 Hz)** and the low group (697, 770, 852 and 941 Hz). Each symbol or digit is sent with one high group and one low group tone. Thus a complete Touchtone decoder must have at least seven decoder blocks to

*AT&T Trademark.

**The fourth high group tone (1633 Hz) is shown for completeness, but not widely used by hams since 12 button pads don't generate it.

Fig. 1(a). Schematic diagram.



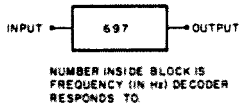


Fig. 1(b). Tone decoder block.

Fig. 2. Frequency pairs for Touchtone symbols. Two tones are transmitted simultaneously. For example, digit 1 is 697 and 1209 Hz, etc.

LO GROUP \ HI GROUP	1209Hz	1336Hz	1477Hz	1633Hz
697Hz	1	2	3	A
770Hz	4	5	6	B
852Hz	7	8	9	C
941 Hz	#	0	*	D

A,B,C,D NOT NORMALLY USED

detect the presence of any of the legitimate tones (see Fig. 3). The block indicated as LOGIC contains digital gates to convert the 2-out-of-seven decoder outputs to 0-9, # and * outputs (references 5 and 6).

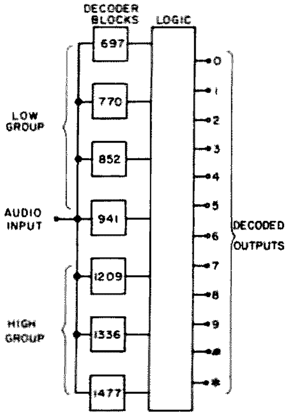
Band-Splitting

The simple Touchtone decoders commonly used feed audio directly from the communications link (radio receiver, telephone line, etc.) to the inputs of the decoder blocks as shown in Fig. 3. If system audio level can be controlled, and if too many extraneous signals aren't present, this scheme works well. However, on a typical radio link (and especially on an amateur repeater) these conditions don't exist. First, there is usually an imbalance in tone levels between the high and low groups called "twist." Bell System compatible Touchtone pads emphasize high group tones to allow for attenuation of the higher frequency tones in telephone lines. Additional imbalance (twist) often occurs due to the imbalance of audio tailoring between transmitters and receivers, particularly in FM systems. Also, recovered audio varies depending on the amount of audio transmitted via the link. Secondly, on any link, and particularly amateur repeaters, a wide variety of squeals, whistles, grunts, clicks and other barnyard noises occurs frequently.

With these uncontrolled inputs, the Touchtone decoder can misbehave, causing "falsing," which can be either an output without any valid input signal, or non-recognition of a valid signal in the presence of unwanted noise. As described in the Signetics application literature, the PLL detection bandwidth varies as a function of signal amplitude applied to the chip. Thus, at low levels, a signal only slightly off frequency in one tone channel might be recognized, whereas at high levels, a tone well off the mark might cause a false response.

Obviously, some means of level control is needed to get around this problem. One commonly used method is a limiter (just like in an FM receiver). This is a fine idea, except that a limiter alone won't do the job for two reasons. First, a limiter exhibits "capture effect." This just means that if two signals of unequal amplitude are fed to a limiter, the stronger one predominates, further suppressing the weaker signal. This would make any "twist" even worse than it was without the limiter. Secondly, limiters, because they are nonlinear, generate spurious mixes and harmonics that could generate extra frequencies which can foul up decoder operation. The solution is easy – use two limiters, one for the high group and another for the low group. And to keep out spurious crud, feed each limiter with only those frequencies present within its respective group, as in Fig. 4. The bandpass filters make up what is called a band-splitting filter. Each passes only those frequencies required by the individual decoder group, so the problems of emphasizing "twist" and generating unwanted slop are circumvented.

Fig. 3. Simplest 12 button pad Touchtone decoder.



Practical Band-Splitter

Fig. 5 shows the schematic diagram of an easy-to-duplicate band-splitting filter. Each half of the filter consists of two cascaded bandpass active filters (they act like LC tuned circuits) which are staggertuned, so that they pass one frequency group, while rejecting the other group. The bandpass sections are so-called multiple feedback active filters whose Q and center frequencies were empirically derived (fudged to fit). Anyone so inclined can design another filter, probably better, using the techniques outlined in Chapter 8 of reference 7 and Chapter 5 of reference 8. The filter circuit is simple and cheap to build, since all four operational amplifiers used are contained on one chip in the Motorola MC3401 or National LM3900 integrated circuits. The limiters which follow the band-splitters are very simple, consisting of a pair of back-to-back germanium diodes for each section. All in all, this may be pretty crude, but it works well. Construction of the filter is non-critical since it operates at audio frequencies. Several of them have been constructed using both vectorboard and PC board construction with no layout or parts placement difficulties encountered. For room temperature operation, all frequency determining components are non-critical, but refer to a later section for suggested extended temp range component types.

Tune-up is relatively simple. It is best done by first separating the four individual bandpass sections by opening the A-B and D-E connections. Connect an ac voltmeter to A, and apply dc power. The meter should read 0 volts ac. Now connect a source of 697 Hz sine wave audio to the input line and set the input level to about .1 volts rms. Adjust R3 for resonance as indicated by maximum deflection of the ac voltmeter. (Although the schematic shows a potentiometer here, I selected a fixed resistor of proper value and soldered it in place – pots cost too much.) Now connect the meter to point C and a 941 Hz signal to B. Adjust R8 for maximum meter reading. The low group filter is now tuned, so reconnect A to B. Repeat the same procedure for the high group filter, observing the high group connection points. High group tune-up frequencies are 1209 and 1633 Hz.

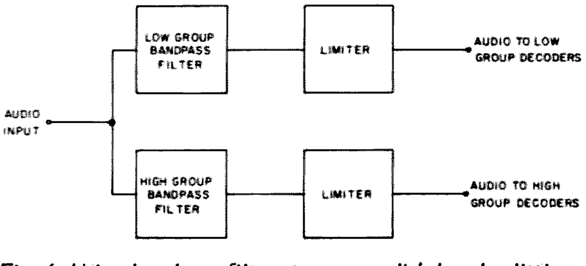


Fig. 4. Using bandpass filters to accomplish band-splitting.

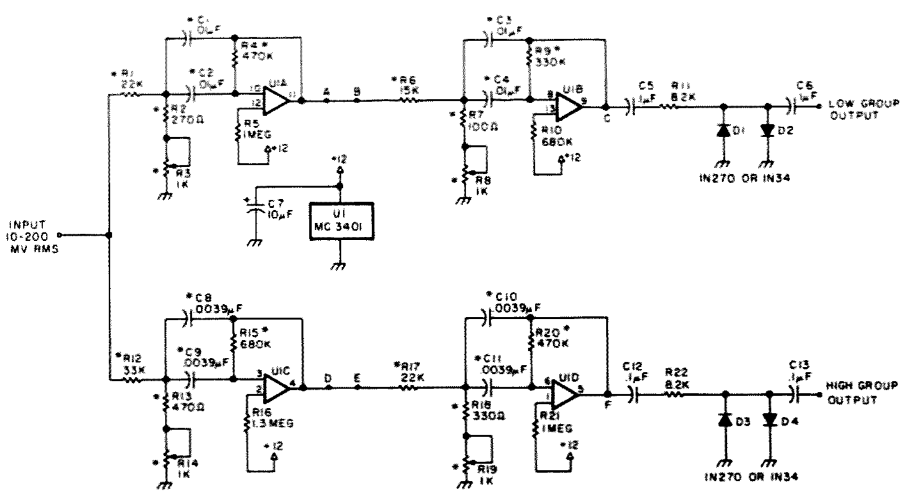

*Fig. 5. Band-splitting filters and limiters. Notes: 1. * indicates tuning components should be 5% tolerance. 2. Other components 10%. 3. +12 V can be 8 to 15 V dc but must be filtered.*

Idealized amplitude response curves are shown in Fig. 6. Almost 20 dB rejection of the opposite group and out-of-band frequencies is provided by each section. In-band ripple depends on accuracy of tuning. It has varied between 3 and 6 dB for the filters I built. You may notice that the high group filter extends beyond 1477 Hz.

Actually, there is another frequency used in some systems to expand the symbol set. Few available pads have the fourth group of buttons, although they can be added. Anyway, this lengthening of the high group filter will cause no harm in a 12 button pad system.

Further Improvements

Using the band-splitting filter and limiter combination vastly improves decoder operation as described above, but there is still room for improvement. The 567 decoder IC, it appears, was designed primarily to drive relays. One would think that it should drive logic circuits as in Fig. 3 just as well. Unfortunately, this is not necessarily so. Relays have an appreciable time lag in their operation due to their electromechanical structure. This delay can range from perhaps a millisecond to 100 milliseconds or so, depending on their size. The 567 needs this lag. Certain combinations of input signals or noise pulses can cause short duration chattering of the 567 output. Relays ignore these spurious outputs because they are usually only 100 microseconds to a millisecond long. However, TTL circuits take less than 100 *nanoseconds* to switch, so they pass on these phony outputs and can foul up system operation. Signetics has some hints for chatter prevention on their data sheet, but I never got them to work well enough to get rid of all of the hiccoughs and burps. My cure was to add a delay circuit between the 567 and logic gates.

Delay Circuit Operation

The delay circuit is shown schematically in Fig. 7. Q1, with its associated resistors, R1 and R2, form a logical inverter. Q2 forms a second inverter with delayed response. Initially, the output of the 567 is high, Q1 is turned on, C1 is at ground and Q2 is off. Thus the collector of Q2 is high, giving the same logical sense as the output of the 567. When a tone appears, the 567 output goes low, and Q1 turns off charging C1 through R2 and R3. When C1 charges to about 1.5 volts, Q2 turns on and its collector goes low. The time required to turn on Q2 is determined by the values of R2, R3 and C1. In this case, the time is about 7 milliseconds. When the tone stops, the 567 output goes high and Q1 collector goes low, discharging C1 through D1 and R4. Q2 turns off when C1 falls below 1.5 volts. Note that the discharge time constant of C1 with R4 is much shorter than the charging time constant of R2 and R3 with C1. This makes the delay time to turn Q2 off much shorter than its turn on time. This characteristic ensures that short pulses and chatter on the 567 output will not pass through the delay circuit, but valid signals longer than 7 milliseconds will. There are other means of getting the same effect, depending on the logic involved, as in references 9 and 10. I used what I believe to be a simple discrete component circuit because I have plenty of them. At any rate, the delay block helps clean up the decoder's output, however it is implemented. If using a 74121 one shot or a 555 timer turns you on – do it! Construction of the delay is super non-critical; even component tolerances matter little. Electrolytic capacitors and carbon composition resistors are fine; just be sure that the transistors used have a gain (HFE) of 150 or more.

By the way, using this delay circuit is not an original idea. Bell Labs designed a more complicated version into the station equipment described in reference 2. Besides getting rid of chatter, timing to determine signal validity is commonly used in tone signaling systems. It eliminates many falsing problems at the expense of slightly lengthened response times. For manual Touchtone use, this extra delay poses no handicap because users are hard-pressed (no pun intended) to punch buttons much faster than two a second. Some automatic calling systems run as fast as 10 digits a second, so care must be taken to tailor decoder response times to use them.

System Assembly

The complete decoder is shown in block form in Fig. 8. Each of the indicated blocks has been described earlier, although not all schematics have been fully described. For more detailed information, see the reference section where I have briefly

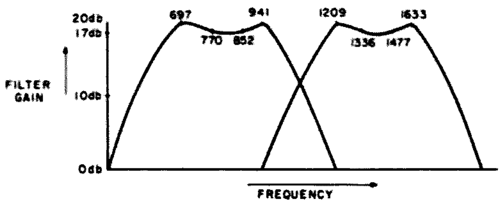

Fig. 6. Idealized band-splitting filter response curves.

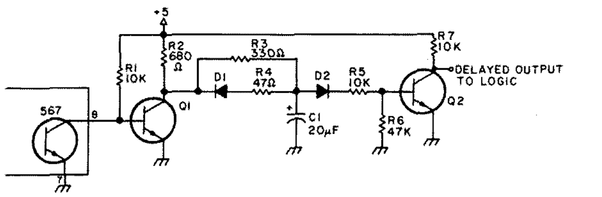

Fig. 7. Decoder delay circuit. D1, D2 – 1N914 or 1N4148. Q1, Q2 – MPS 5172 or other NPN silicon with β over 150.

summarized the content of each article. You can pick and choose the information desired to tailor your own system to individual needs. A more complete schematic diagram is not given here because I doubt that anyone would duplicate my system exactly.

Miscellaneous

Now for a few more tips. First of all, let's look at temperature stability. The Signetics data sheet shows very well how stable the 567 is with temperature, but outside the lab, the resistors and capacitors used to tune the chip can seriously degrade the stability of the IC. Sensitive parts are indicated as frequency-determining components in Figs. 1(a) and 5. Those used in the delay block of Fig. 7 are not at all critical. If the decoder is intended solely for room temperature use, ordinary carbon composition resistors and mylar capacitors are fine for critical components. For extended temp range operation, more stable parts will be needed to prevent degradation of the decoder's performance. Resistors should be of the precision film type. A good compromise between price and performance is the use of semi-precision Corning RL-07 or IRC Metal Glaze™ resistors. For tuning capacitors outside the range of 32 to 122° F, mylar capacitors are a poor choice. Better choices are capacitors with polystyrene or polycarbonate dielectrics. An excellent choice of polycarbonate capacitors is the Siemens B32540 series available from Newark Electronics in Chicago. They are ideal for printed circuit boards – they are small, relatively inexpensive and *very* temperature stable. I've used them from minus 65° F to plus 200° F with a total capacitance drift of less than two percent!

Finally, a word or two about tuning the individual 567 decoder blocks. Neither the application notes nor the data sheet give any clues as to the proper method. I once saw directions for adjustment in a decoder instruction book that said to apply signal and adjust the pot first in the clockwise direction until the output goes low, then adjust in the counterclockwise direction until it goes low. The builder was to note both potentiometer settings and set the pot midway between them. Great! The only thing they neglected to say was that the two settings were about 5° apart. You would need a microscope and a surgeon's steady hand to set the blasted thing that way.

I've had the most success with tuning the vco by adjustment of its internal free-running frequency. One way to do this is shown in Fig. 9(a). The frequency counter reads the frequency of the vco inside the 567. Simply adjust R2 for the frequency you want the decoder to respond to. If you don't happen to have a frequency counter, but you do have an oscilloscope and a signal source (such as a Touchtone pad), use the setup of Fig. 9(b). The oscilloscope is used to display a Lissajous figure. First set the signal source to the desired frequency, then adjust R2 on the decoder for a stable 1:1 Lissajous pattern (examples of Lissajous figures can be found in the ARRL *Radio Amateur Handbook*). In this setup the figure will not be a circle because the signal at pin 5 of the 567 is not a sine wave. A 1:1 pattern is easily achievable though, strange as it may appear. For either measurement method two precautions will ensure correct adjustment. Just be sure that (a) the input (pin 3) is grounded through a .1 uF or higher capacitor – stray signals on an ungrounded input will cause measurement error; and (b) the counter or oscilloscope must have a 1 megohm or higher input impedance, or circuit loading will affect the 567's frequency setting.

Conclusion

The PLL tone decoder ICs can be used to make a very good Touchtone decoder. The band-splitters and limiters described herein help clean up signals fed to them and the delay sections clean up their outputs. Simple adjustment techniques can be used to accurately set the decoders precisely on frequency. The circuits and methods given provide guidelines for setting up a practical working system. They have all been tested and duplicated to ensure their accuracy and repeatability. Use them and you'll avoid having to repeat my trials and errors. Good luck! ■

Using a Wireless Broadcaster

--two good ham uses

Wireless broadcasters have been around a long time, but their uses in hamming seem to have been overlooked. This article will suggest two ham uses for a commercially built version of this device, and will describe a simple mod to increase its range and versatility.

The purchased AM unit described and illustrated here is marketed under the names "Vox Box" and "Soundcaster" and is distributed by Olson Electronics. It is intended to plug into the earphone jack of an inexpensive cassette tape player to broadcast the taped music into an AM radio to provide greater volume and better fidelity. The broadcaster is packaged in a plastic pyramid about 2-1/2 inches square and 1-3/4 inches high, and has a 2 foot connecting cord, a miniature phone plug for connection to the cassette player, and a 6 inch insulated wire projecting from the bottom (the device's antenna). It is powered by a 9 volt transistor battery, and draws about 10 mA in use (and only a few microamps when the driving device is shut off, so a battery should last for months).

The gadget's transmitting frequency can be set anywhere between about 1400-1620 kHz, by turning the adjustment screw shown in Fig. 1.

The first ham use for this device is for increasing the volume and improving the audio quality of a 2 meter FM mobile rig. This works especially well if your car has both front and rear seat speakers, but there is a significant improvement with only a front seat speaker. Fig. 2 shows the installation of a broadcaster with a Regency HR2-A. This rig has plenty of volume, but its speaker is mounted in the top of the case and, with the installation as shown, the sound is thrown up under the dashboard where it is largely absorbed by the dashboard's foam padding. The broadcaster-car radio arrangement gives much clearer audio, which can turn a "poor copy" weak signal into a "solid contact." Connecting your 2 meter radio to the broadcaster is accomplished via the rig's speaker leads and a subminiature phone jack. One of the rig's speaker leads can be disconnected from the set's speaker if you intend to use the broadcaster arrangement exclusively, or you can install either a 3-circuit jac or SPDT switch to give you the option of using either th 2 meter radio speaker or th car radio speaker.

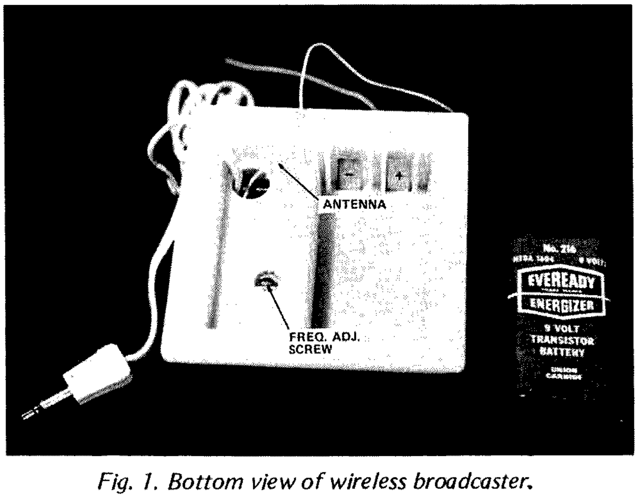

Fig. 1. Bottom view of wireless broadcaster.

The broadcaster is place on the dashboard near th car's AM radio antenna in th center of the windshield; it little wire antenna couples very strong signal into the ca

Fig. 2. Broadcaster used with 2 meter rig in car.

Fig. 3. His/hers arrangement.

.ntenna, even from several nches away. If your car has a vhip antenna, of course, the ›roadcaster should probably ›e placed on the dashboard ide nearest the whip. \dvance the volume control ›f the amateur rig just far :nough to produce a clear ignal, and adjust the volume vith the car radio's volume :ontrol; too much audio from he amateur rig will overdrive he broadcaster, causing listortion. The only minor lisadvantage of this setup is ome background noise from he car radio during trans-nitting. If this is objection-ble, the only simple cure is o turn down the car radio olume control before reach-g for the mike.

Fig. 3 shows a multiband ›ortable radio with broad-:aster in my wife's car. This is . his/hers arrangement: mon-toring FM repeaters and air-craft calls for me, FM broad-cast band music for her.

The broadcaster described normally has a range limited to 3-6 feet or so, depending upon obstructions in the signal's path, sensitivity of the AM radio, etc. By increasing the broadcaster's range, it can be used with an AM portable radio (prefer-ably of the shirt pocket size variety) to remotely monitor any VHF or HF rig in your shack. It's nice to be able to listen in on an interesting roundtable QSO or net, or to monitor the mobile activity on a channel while going to the kitchen for a cool one, upstairs to answer the door-bell, and so forth. With the setup to be described you can just plug in the broadcaster, grab the AM portable, and monitor what's happening on frequency while going about other errands.

However, *carefully observe* the FCC's regulations re-garding unlicensed trans-missions in the broadcast bands: (1) transmitting power not to exceed 100 milliwatts; (2) antenna length not to exceed 10 feet; (3) no inter-ference to be caused to broadcast band listeners. The first two of these conditions are no problem, but the third may be impossible to satisfy if you live in a crowded apart-ment building, or if you have any neighbors less than 25 feet from where you'll be using the broadcaster. So be a

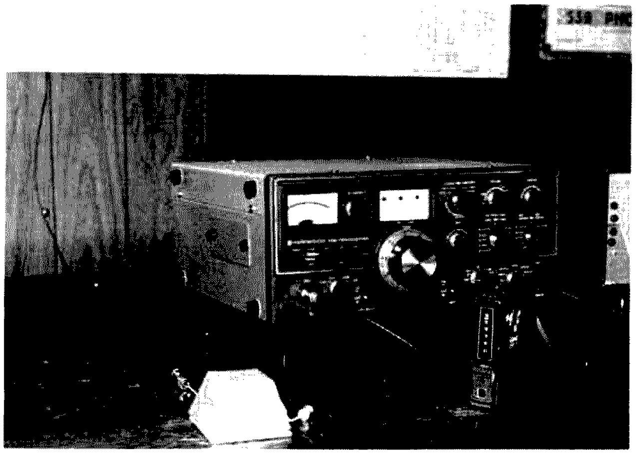

Fig. 4. 8 foot antenna added to the broadcaster.

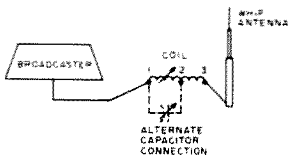

Fig. 5. Wiring diagram of broadcaster with whip antenna.

good neighbor, and *stay legal.*

The simplest method of increasing the broadcaster's range is to add a length of wire to its short antenna. Fig. 4 shows a portion of an 8 foot length of #22 hookup wire connected to a broadcaster with an RCA-type phono plug and jack. The wire is thumbtacked to the wall and across the ceiling. With this installation in my basement shack, the amateur rig can be heard clearly (on the little AM portable shown in the picture) throughout the upstairs of my ranch house. There are, of course, a few "dead spots" in the house where furnace ducts, house wiring, etc., interfere with reception. Adding any length of wire to the broadcaster's antenna will load the oscillator and change its operating frequency slightly, and you will have to move the frequency back to wherever you want to receive it on your AM radio. Also, as would be expected, the AM radio tuning is fairly broad when it is close to the broadcaster, but becomes quite sharp as the radio is moved further away.

A better method for increasing the broadcaster's range, that gives more precise control of the range and a neater installation, is to add a telescoping whip antenna to the broadcaster antenna, matching it with a slug-tuned ferrite loop antenna coil. These coils are sold as a replacement part for fixing portable radios; the one listed in the parts list should be widely available. Fig. 5 is the wiring diagram, and Fig. 6 shows the components wired together and mounted on a scrap of plywood for the initial try at this circuit.

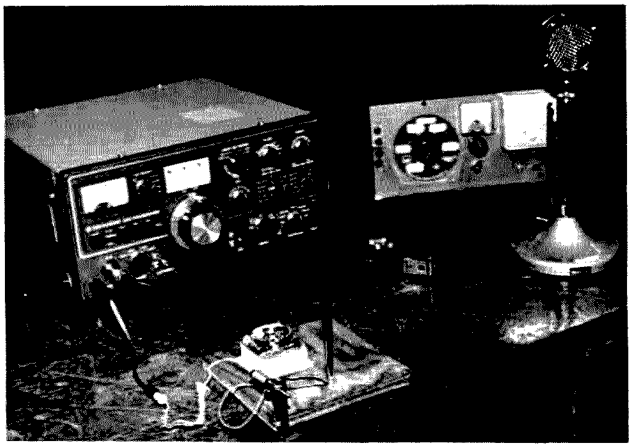

Fig. 6. Broadcaster (with cover removed) connected to antenna coil and whip antenna.

Note that Fig. 5 shows a phantom capacitor connected between terminals 1 and 2 of the coil to resonate it to frequency. The notes on the coil package call for a 100-250 pF variable. However, I found that the broadcaster has better range and is easier to tune without a capacitor.

Tuning is accomplished by alternately varying the whip height and adjusting the coil slug for maximum signal strength at the desired range. This is best done in a series of steps, starting near the broadcaster, and progressively working out to maximum range. Again, these adjustments will slightly detune the transmitting frequency, and you'll have to either retune the portable radio, or tweak the broadcaster's oscillator to the desired frequency.

The whole assembly can be packaged in a small minibox for a neater appearance, as shown in Figs. 7 and 8. The box shown is plastic, and measures 6¼" by 3¾" by 2". It is larger than needed but was conveniently available. As shown in the close-up, the broadcaster was mounted with 2" screws and standoffs through the top of the box. The bottom of the broadcaster faces outward, for easy battery replacement. A bracket for mounting is provided with the coil, which should be mounted near one end of the box so that the slug adjustment screw can protrude through a hole drilled in that end.

This version of the broadcaster also provides "arm chair copy" of amateur band signals in my living room and throughout the house.

Other non-ham uses of the broadcaster suggest themselves: monitoring TV sound from another room (you'll always know when the commercial is ending and it's time to get back to the set), broadcasting music from your hi-fi to the garage while working on your car, and so forth. ■

Parts List

Wireless broadcaster – see text.
Telescoping whip antenna – any broadcast radio or TV replacement type.
Ferrite loop antenna coil – Calectro part no. D1-842.
Mini utility box – Radio Shack part no. 270-627.

Fig. 8. Completed broadcaster with whip antenna in use.

I/O EDITORIAL

from page 130

which is well designed mechanically. They are working on final details and staying up nights to debug their software ... like everyone else in the field. I was impressed by what I saw and you'll be reading more about it.

Dennis Brown of Wave Mate had some excellent reasoning behind his use of wire-wrap for his system. His is the only system which uses one set of identical boards for every module ... and the only one which an experimenter can get into and make changes on with relative ease. We've been promised articles by Dennis on wire-wrap and the Wave Mate system concept.

Godbout was wringing out the software for the first 16-bit hobby system ... the PACE. This may turn out to be a winner when hobbyists get more into developing and selling small business systems. An article has been promised on the system, which should put it into perspective.

Just about everywhere I went I was first met with skepticism about the need for *Kilobyte Magazine* ... after all, with *Byte, Interface, Creative Computing*, maybe a *Microtreck*, and a bunch of club newsletters, who needs another big magazine? After explaining the philosophy behind *Kilobyte*, I found everyone enthusiastic. *Kilobyte* not only will be doing different things from the other publications, it will be providing a very valuable service. The reviews of hardware alone should pay every subscriber several times over in saved money and time. The software programs and routines should do the same.

Sphere, which has had a lot of management problems which have resulted in delays in filling orders, a BASIC emulator which crept along at a snail's pace, and other miseries in the past, has been reorganized and promises a better day to come.

MITS is still the biggest and the champ. We've been promised an article on their Zilog CPU system which is due out in a couple months ... and they have a lot of other fascinating things brewing which will intrigue the hobbyist and delight their growing network of sales outlets.

SWTPC in San Antonio has been doing very well with their 6800 kit and now is shipping 4K BASIC ...with 8K coming up. Their cassette interface and line printer are doing well and articles are scheduled from them on these.

I've some taped interviews with a few firms which might be of interest to computer clubs ... these will be duplicated and announced soon. I'll also have a more detailed report on the trip, complete with pictures in both *73* and *Kilobyte*. There is absolutely nothing like a personal visit to find out who is doing what ... which firms are for real and which are made up mostly of smoke.

BEGINNER'S COMPUTER MAGAZINE

There is just too much happening too fast in the small computer field for *73 Magazine* to cover it all without shoving amateur radio out almost entirely. Obviously a second magazine is needed to help readers keep up with this fantastic and growing field ... hobby.

It is a difficult decision because so much of hobby computing and amateur radio are tied together ... virtually *all* of the serious applications for hobby computers have so far been in amateur radio ... for exotic Teletype stations, control of amateur repeaters, control of amateur antennas for DXing and for Oscar amateur satellite predicting and antenna pointing ... etc.

Kilobyte Magazine will attempt to give you the most thorough coverage of new equipment and kits possible ... with no punches pulled. If you are into building your own computer, keep careful notes of what you have to go through ... problems with ordering, getting delivery, with getting missing parts and replacing defective parts, with instructions, with getting the equipment put together, with getting it working, with interfacing it, and so forth. Write up your report so your experiences can help others through the problems you met ... and hopefully conquered. Feedback like this will help manufacturers get their act together too ... and we sure could use a lot of that.

Kilobyte Magazine will be providing you with as much program info as possible. In addition to articles on programming, you'll have as many useful programs as we can get. If you've worked out some routines for any of the hobby computers, here is a way to cash in on them ... send the program to *Kilobyte*. It may be a program for checking memory, for generating random numbers, for playing a game, for aiming a beam antenna, for moving things around in memory, for checking your CPU, whatever. Your work can get you known ... and cash ... and will, most important of all, help a lot of newcomers.

Kilobyte Magazine will be checking out the newest equipment in the *73/Kb* lab ... which is growing every day. It presently has an Altair with disk, Imsai, Wave Mate, Ebka, Lear terminal, Southwest Tech TVT-II, Burroughs terminals, Viatrons, HAL terminal, all sorts of memory boards, and much more promised ... such as a 7 Meg disk for the Altair ... etc. *Kilobyte Magazine* is the *only* hobby computing magazine with its own test lab.

KEEP IT SIMPLE

Every effort will be made to keep as much as possible of the info in *Kilobyte* simple, as a way for the newcomer to hobby computing to bootstrap himself into the field. I am not unaware that just about all of the other computer hobby publications are alive with buzzwords and are more aimed at the PhD than the beginner. *Kilobyte* will even have a glossary of computer terms to help you get through the articles!

The first issue of *Kilobyte* will be the January issue, out in late November. If the demand for it is anything like that for the first issue of *Byte*, it may shortly be worth more than the charter subscription price of $12. All you have to do to miss out on the first issue is wait around to see how *Kilobyte* looks before you subscribe ... the way a few thousand very unhappy *Byte* readers did.

Single copies will be $2 and the regular subscription rate is $15, with a special Charter Subscription rate of $12 until the end of November.

WHAT'S A COMPUTER STORE?

While passing through Windsor Locks (CT) the other day, I stopped at the new computer store just off Route 91 to see what they were up to.

The Connecticut store is an offshoot of the Burlington, Mass. (Boston) computer store and features mostly MITS equipment. It is a place to get boards, see systems up and running, get some help in understanding what you may need for what you want to do, and get help in getting your own gear running. George Gilpatrick, shown in the photo, welcomes visitors at the Computer Store, 63 South Main.

Madeira Beach FL 33708

Charles Apgar didn't look much like a James Bond type of spy as he worked in the den of his Westfield, New Jersey home that June morning of 1915. A slight man, precise in speech and dress, he lived with his wife and two small children in this quiet suburban town. Intrigue had never played a part in his life. But the mail that day was to bring him a letter that would soon cast him in the role of a "super sleuth" for his government.

If you had glanced around his den-workshop, you would

WASHINGTON IS SHOCKED BY ATTACK ON THE ORDUNA

Officials See Disavowal of Implied Promise of Germany to

have seen the results of a remarkably inventive mind. Ever since that windswept day in January, 1903, when Guglielmo Marconi sent the first wireless message from Cape Cod across the Atlantic to King Edward in England, Apgar had been interested in the new art of wireless. By 1910 he was patterning his experiments along the lines of work being done by Marconi and DeForest.

On one side of the room was a complete receiving and sending station with wires radiating out into the yard and up to the treetops. Against another wall sat his latest invention, just perfected after two years of work. It was a device for transferring messages sent through the air onto wax cylinders, which could be played back on a Edison phonograph. No one had ever done this before, and the experts had said no one ever could, but that statement was only a challenge to Apgar and it had spurred him along to the completion of his project.

The momentous letter that arrived that day was from Lawrence J. Krumm, Chief Radio Inspector, Department of Commerce of the Port of New York, and read:

"My dear Mr. Apgar: Will you be kind enough to call me up Monday morning from your place of business? I am very desirous of getting in touch with you immediately, as I believe you can be of considerable service in a good cause."

You may imagine Apgar's thoughts as he read, and reread, the letter. In what way could he be of "considerable ervice in a good cause," he wondered. He decided it urely must have something o do with Krumm's visit to is home several evenings efore. Knowing the Chief Inspector's interest in radio, Apgar had invited him to ome and see his completed ecording device demontrated. It had been a pleasant evening, with Krumm more than enthusiastic about the invention.

Next morning Apgar called the Chief Inspector's office from the Franklin Automobile Company in New York where he was employed, and agreed to come right over. Once there, it was suggested that they leave immediately for an interview with William J. Flynn, Chief of the United States Secret Service. Now Apgar was indeed mystified, as this service was the FBI of those days, and he could not think of any way he would be involved with it.

On the way, Krumm explained why he had written to him. As both men were aware, two powerful transatlantic stations had been constructed by the Germans in this country, one at Sayville, Long Island, the other at Tuckerton, New Jersey. Although World War I flamed in Europe, the United States was still neutral, so these stations had been granted temporary licenses for sending commercial messages to be received by POZ Nauen, Germany.

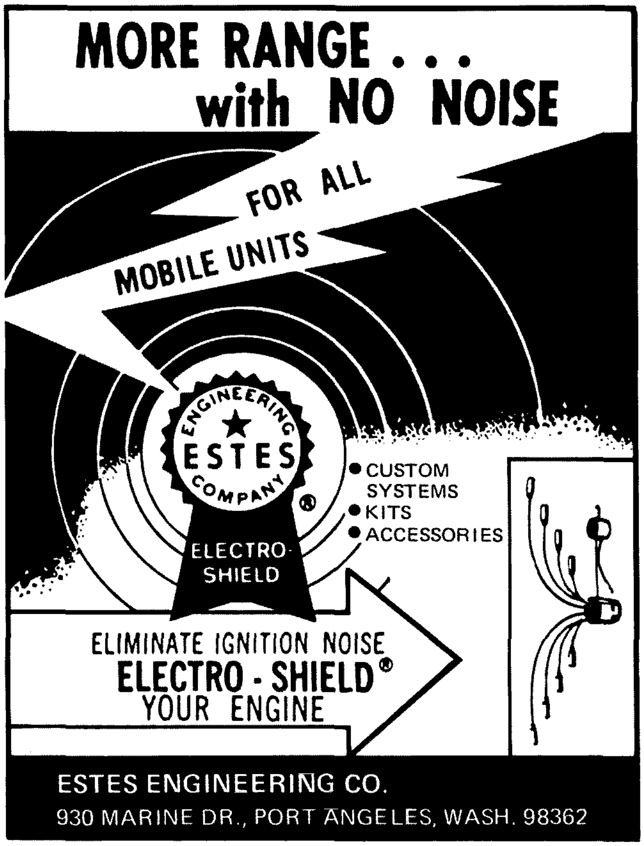
Krumm went on to tell him how the supposedly innocent messages were suspected of conveying word to German submarines and cruisers based in the Atlantic. Accusations were flying fast; Washington was deluged with complaints from the English and French ambassadors. Too often allied ships were sunk by submarines obviously well informed as to the ships' sailing dates and sea lanes. The problem was to prove this. But so far the Navy monitoring stations at Fire Island, New York Harbor and at Arlington, Virginia had been able to find no differences between what was filed with them and what was sent.

Now Flynn, as head of the Secret Service, was ordered to find out what was "going on." His knowledge of wireless being slight (as was that of most people in 1915), he had called on Chief Inspector Krumm to see if he had any suggestions to improve monitoring done by the Navy censors. By chance (and how often great happenings depend on such a twist of fate), his call on Krumm was the next day after the Inspector had been at the Apgar home. Of course the recording device was described and Flynn had asked for an interview with Apgar as soon as possible. So the letter was sent.

The meeting with Inspector Flynn was brief. He knew that Krumm had told Apgar of the problem, so he came at once to the point. Would he be willing to transcribe on his recording machine all messages sent out by the Sayville station over a period of two to three weeks? As they only transmitted at night, it would mean a long, tiresome process for Apgar, but there was no one else in the country who could perform this service.

Apgar didn't hesitate to accept the commission. This was a field in which he was at home and he looked forward to applying his invention to the "good cause" he finally understood. Besides, as he recorded later, he thought it would be a pleasure to "aid in taking the say out of Sayville."

He wasted no time in assuming his role as a spy for his government. The interview at the Secret Service office was at eleven in the morning and he began work the same evening. According to his private papers, he first scoured the city for blank cylinders. That meant some "tall hustling." Hurrying back to Westfield, he set up two Edison phonograph machines in his home. In that way he



could switch the receiver from one machine to the other without missing a dot or dash of the transmission. Promptly on the night of June 7, and into the morning of June 8, he recorded on cylinders the messages sent out by WSL Sayville. Early the next day he transcribed them and personally delivered them to the Secret Service office to be turned over to the Navy Department for comparison with the ones filed and received by the monitors.

This went on for fourteen consecutive nights, starting at eleven and often running as late as three or four in the morning. Chief Flynn had not exaggerated. It was a long vigil. By June 21, he had filled 175 cylinders and transcribed 25,000 words. He confessed in a radio interview with WJZ New York in December 1934 that he did become quite tired and lost considerable weight during that time, but he was buoyed by the excitement and the results.

The messages monitored and those taken on the cylinders showed definite discrepancies. It might be a word repeated or numbered messages not in sequence – variations that conveyed a special word to the receiving station in Germany. The cylinders, with their slower and faithful reproductions, picked up what the Navy monitors had not been able to do. Chief Flynn turned all recordings over to Secretary McAdoo of the Treasury Department, where their contents by specific statute became inviolate. However, Apgar, in this same interview with WJZ, gave some examples of the original messages and the information they really gave.

"Send always invoice before shipping knives." signified instructions to POZ Nauen to be relayed back to German submarines in the Atlantic.

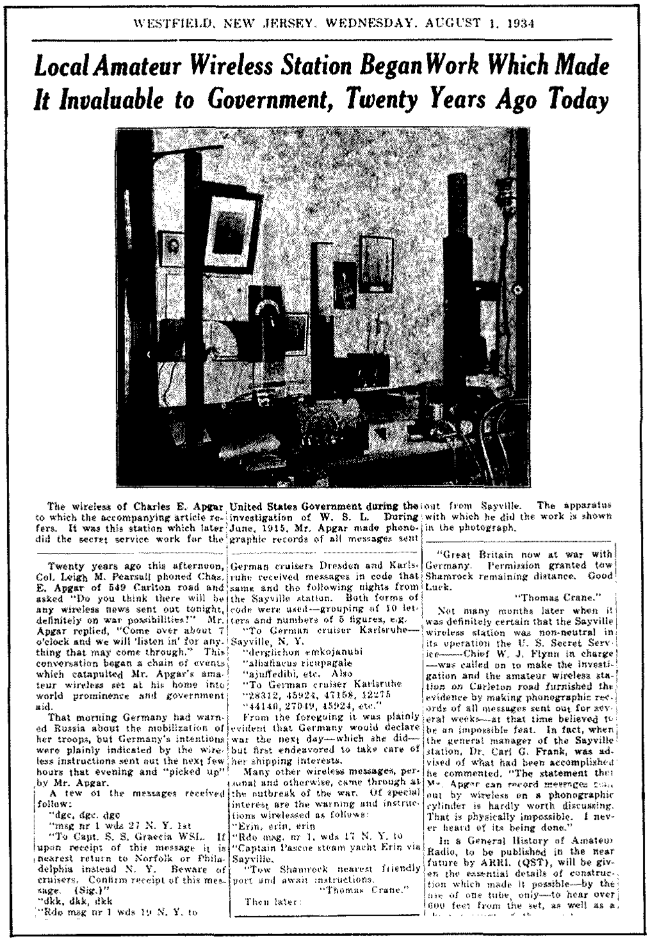
"Is our office running as usual with Sampler alive and attending? Please wire." was giving information on dates and routes of Allied ships leaving the ports of New York and Philadelphia.

These recorded messages proved that the station had indeed been violating the neutrality of the United States. As a result, both Sayville and Tuckerton were taken over by our Navy Department: Sayville on July 8, 1915 and Tuckerton shortly afterward.

At first the seizure of Sayville was spoken of in the press as a precautionary measure, according to an article in the *Wireless Age* of September 1915, but ten days later New Yorkers were surprised to read in the *World* that Sayville had been closed after investigation by the Secret Service, and that the phonograph recordings made by Charles E. Apgar of Westfield, New Jersey had established the true nature of the messages sent by the German station.

The press described his work for the Navy Department as "the most valuable ever rendered by a radio operator to his country." Apgar was pleased by this citation, and others, but he also spoke of a statement made in an interview by Dr. Karl Frank, the disgruntled manager of the WSL Sayville. After the closing of his station, the manager said, "That Mr. Apgar can record messages on a phonograph cylinder is hardly worth discussing. That is physically impossible. I have never heard of its being done."

We suspect that Apgar, the experimenter and inventor, was as well honored by this "citation" as by any he received. ■



WESTFIELD, NEW JERSEY, WEDNESDAY, AUGUST 1, 1934

Local Amateur Wireless Station Began Work Which Made It Invaluable to Government, Twenty Years Ago Today

The wireless of Charles E. Apgar to which the accompanying article refers. It was this station which later did the secret service work for the United States Government during the investigation of W. S. L. During June, 1915, Mr. Apgar made phonographic records of all messages sent out from Sayville. The apparatus with which he did the work is shown in the photograph.

Twenty years ago this afternoon, Col. Leigh M. Pearsall phoned Chas. E. Apgar of 549 Carlton road and asked "Do you think there will be any wireless news sent out tonight, definitely on war possibilities?" Mr. Apgar replied, "Come over about 7 o'clock and we will 'listen in' for anything that may come through." This conversation began a chain of events which catapulted Mr. Apgar's amateur wireless set at his home into world prominence and government aid.

That morning Germany had warned Russia about the mobilization of her troops, but Germany's intentions were plainly indicated by the wireless instructions sent out the next few hours that evening and "picked up" by Mr. Apgar.

A few of the messages received follow:

"dgc, dgc, dgc
"msg nr 1 wds 27 N. Y. 1st
"To Capt. S. S. Graecia WSL. If upon receipt of this message it is nearest return to Norfolk or Philadelphia instead N. Y. Beware of cruisers. Confirm receipt of this message. (Sig.)"
"dkk, dkk, dkk
"Rdo msg nr 1 wds 19 N. Y. to German cruisers Dresden and Karlsruhe received messages in code that same and the following nights from the Sayville station. Both forms of code were used—grouping of 10 letters and numbers of 5 figures, e.g.

"To German cruiser Karlsruhe—Sayville, N. Y.
"derglichon emkojanubi
"albafiacus ricupagale
"ajuffedibi, etc. Also
"To German cruiser Karlsruhe
"28312, 45924, 47168, 12275
"44140, 27049, 45924, etc."

From the foregoing it was plainly evident that Germany would declare war the next day—which she did—but first endeavored to take care of her shipping interests.

Many other wireless messages, personal and otherwise, came through at the outbreak of the war. Of special interest are the warning and instructions wirelessed as follows:

"Erin, erin, erin
"Rdo msg. nr 1, wds 17 N. Y. to
"Captain Pascoe steam yacht Erin via Sayville.
"Tow Shamrock nearest friendly port and await instructions.
"Thomas Crane."

Then later:

"Great Britain now at war with Germany. Permission granted tow Shamrock remaining distance. Good Luck.
"Thomas Crane."

Not many months later when it was definitely certain that the Sayville wireless station was non-neutral in its operation the U. S. Secret Service——Chief W. J. Flynn in charge—was called on to make the investigation and the amateur wireless station on Carleton road furnished the evidence by making phonographic records of all messages sent out for several weeks—at that time believed to be an impossible feat. In fact, when the general manager of the Sayville station, Dr. Carl G. Frank, was advised of what had been accomplished he commented. "The statement that Mr. Apgar can record messages sent out by wireless on a phonographic cylinder is hardly worth discussing. That is physically impossible. I never heard of its being done."

In a General History of Amateur Radio, to be published in the near future by ARRL (QST), will be given the essential details of construction which made it possible—by the use of one tube, only—to hear over 600 feet from the set, as well as a

The Benefits of Sidetone Monitoring

-- and how to do it

73 Magazine *Staff*

"Sidetone" is used in amateur circles to denote a tone from a CW keying monitor. But the term comes, of course, from the telephone industry, where a certain amount of the voice energy feed into the microphone unit of a telephone handset is deliberately coupled to the receiver unit in the headset so a person can barely hear himself talk. It was determined that transmission efficiency was improved by this scheme and a person using a telephone tended to maintain a steadier, more level talking level — especially in a slightly noisy environment. The method must have some value, since, besides in the telephone system, one will find audio sidetone employed in various commercial radio transceivers, military transceivers and aircraft communications transceivers. This is *in spite of* the fact that these transceivers also employ various advanced forms of speech processing designed to keep the average modulation level as high as possible.

Amateurs might also consider the value of using audio sidetone in both mobile and fixed station installation. The use of such sidetone is mainly possible where a handset is used or a microphone/headset combination is employed. Otherwise, there is the possibility of audio feedback taking place unless a good directional microphone is used while the audio sidetone is monitored via a loudspeaker.

Simple Methods

A few simple methods for making the necessary audio sidetone interconnection in a station setup are as follows:

1. If a separate transmitter and receiver are used, one can make an interconnection between the microphone amplifier stage in the transmitter and the audio preamplifier stage in the receiver. This should be done after the volume control in the receiver and utilizing a separate potentiometer to control the level from the microphone amplifier output in the transceiver. Fig. 1 shows the basic idea. The audio stages in the receiver must remain activated during transmit periods for this scheme to work or the receiver transmit/receive function suitably rewired to accomplish this. A relay is used to break the audio sidetone circuit when in the receive mode, since feedback can easily result if the high receiver loudspeaker output level in the receive mode gets back into the microphone circuit.

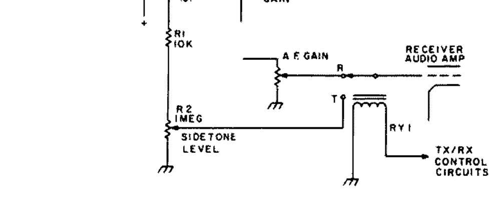


Fig. 1. Typical audio sidetone interconnection between separate transmitter and receiver or sections of a tube-type transceiver. The only added components are C1, R1, R2, and RY1.

2. If a transceiver is used, it may or may not be possible to utilize a scheme similar to the above between the receiver and transmitter portions of the transceiver. Some transceivers utilize complicated switching schemes for transmit/receive functions and the dual use of the low level audio stages both in the transmit function (as microphone amplifiers) and in the receive mode (as preamplifier after the product detector stage). In most transceivers, however, these functions are kept separate and one can switch the receiver section audio amplifier stages, via a relay, to pick up the output of one of the microphone preamplifier stages on transmit. A separate potentiometer should be used to control the level being fed into the receiver section audio amplifier stages and this potentiometer serves as the audio sidetone level adjustment.

3. The simplest scheme to

achieve audio sidetone monitoring is via a separate small amplifier which is used between the microphone and the station loudspeaker or headset and is energized only during transmit periods. Any one of the number of simple amplifiers can be used, such as the solid state PA amplifier modules available from Lafayette Radio or Radio Shack for about three dollars. Although called "PA" modules, these modules will not exactly create enough undistorted volume to disturb the household. However, they are very suitable for audio sidetone purposes since they have a high impedance input which can be bridged across any microphone output without greatly affecting it, and their low impedance output can be used to drive either a loudspeaker or a low impedance headset connected across a receiver's output. At the low levels needed for audio sidetone monitoring, their distortion is very low. They require 6 volts for operation, and this can be obtained in tube-type transceivers by a simple half wave rectifier and filter across the filament line. Fig. 2 shows a typical arrangement. For mobile transceivers they can be powered via a dropping resistor directly from the battery line.

The secret to obtaining maximum benefit from audio sidetone monitoring is in the adjustment of the sidetone level. You have to trick yourself, the same as the telephone company people do! Pick up your telephone and listen for the audio sidetone level as you speak to another party. It has been carefully chosen, as you will be inclined to "speak up" consistently rather than whisper into the handset. If the sidetone level were too loud, you would be inclined to speak more softly. If it is too comfortable to hear, you would be inclined to become intrigued with the reproduction of your voice, but not necessarily inclined to maintain a steady voice level. The sidetone level has been deliberately chosen so you *can just hear it*, and this is the adjustment to make for monitoring the audio sidetone level in a station. After a while, you will become unaware of the sidetone level, but you will try to speak at a consistent output level that allows you to detect the presence of the sidetone.

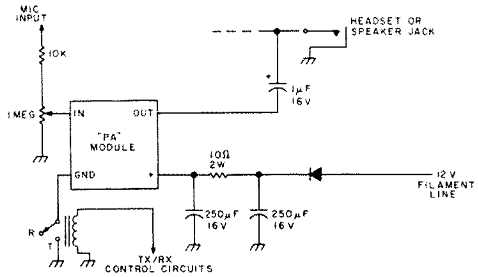

Fig. 2. Use of an inexpensive PA module amplifier provides audio sidetone with a minimum of circuit modifications.

Audio sidetone monitoring is a relatively simple accessory to add to any station. The simplicity of the idea has probably been obscured by the usage of so many other speech processing devices such as audio compressors and clippers. However, if one can add only 1 or 2 dB more effective transmission efficiency to a station by audio sidetone monitoring and completely without any added distortion of the modulated signal, the idea seems worthy of a try. ■

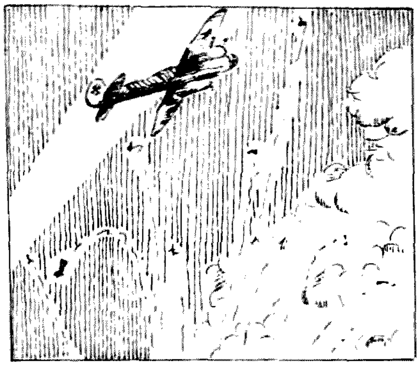
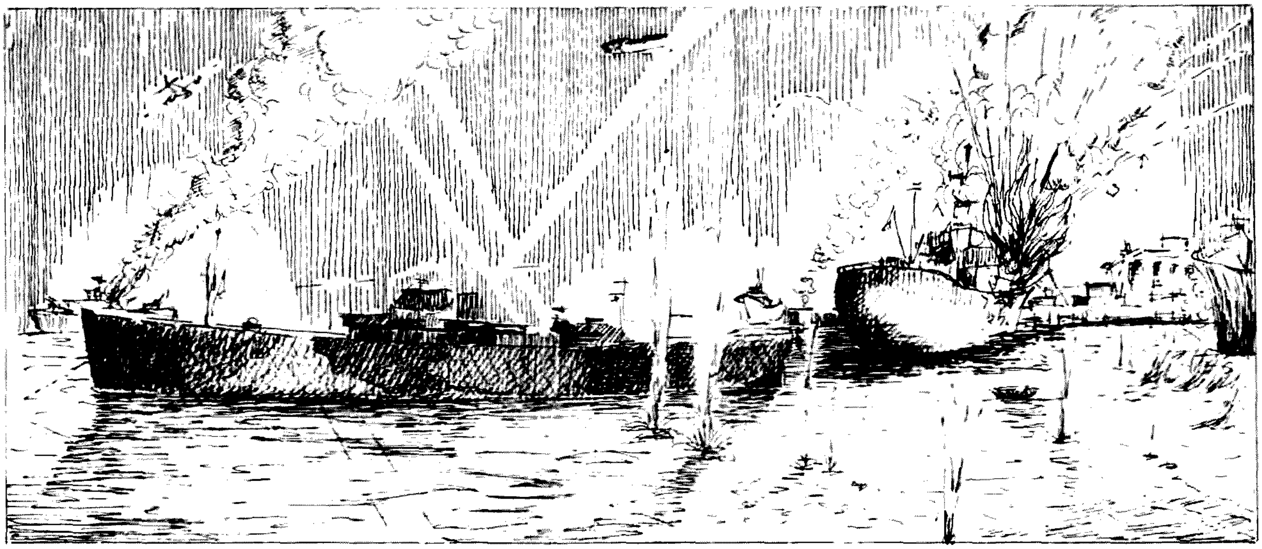
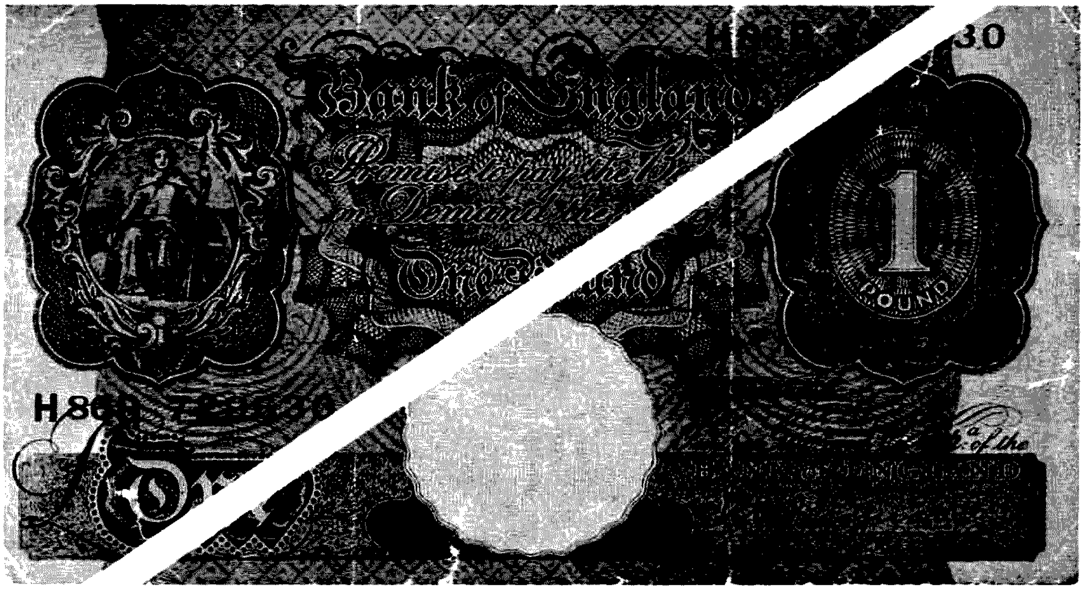
Paolo

Amateur radio is a rewarding hobby; one dividend is a wider window on the world, and another is technical expertise, but I think that most important is the friends we make. Some we keep, but the currents of life eddy and some drift away — until a page in a logbook or a card in a file brings them back and we are caught in a net of memories. Recently I came across a memento that sent the years spinning — a phony British pound note.



Illustrations by Carl Jackson





Paolo never told me his last name, and I forgot his call many years ago. It wouldn't do to mention it even if I could remember, not without knowing first how he arranged his life after the war. I'm satisfied that he isn't one of the few dozen licensed Libyan 5As; perhaps he finally went home to Italy, and one day he might see this magazine. I'd like to hear from him.

1943 opened on a note of optimism following the victories at Stalingrad and El Alamein, and the Eighth Army was pushing hard against the rear guard of the Afrika Korps. Steady pressure was essential to deny Rommel any opportunity to pause and exploit the defenses of Tunisia's Mareth Line. Montgomery required thousands of tons of supplies daily, and Tripoli was the new forward depot. Heroic work by underwater demolition and salvage crews had opened a gap through a blockade of seven ships the Germans had filled with concrete, booby-trapped and sunk in the narrow harbor entrance, and now the port was congested with laden freighters.

Along the Spanish Mole, on the seaward side, jetties were being worked around the clock, but the cargo handling facilities were limited and soon after sunset every evening the Luftwaffe arrived from Sicily. In the center of the harbor, in close company with wrecked Axis shipping and other Liberties newly arrived from Alexandria and Port Said, the *Edward Everett* was anchored awaiting space at the jetty. Our readiness to discharge the cargo of Crusader tanks packing the holds was unmatched, and every bomb that fell nearby added to our zealous impatience. So did the photo plane which checked the situation every afternoon and sped back to Sicily with tattletale negatives and our hearty wishes for a crash at sea.

Between us and the jetties along the mole where eventually we would unload our tanks, and about three hundred yards away, lay the *Empire Voyager*, down to the marks with thousands of tons of bombs and ammunition. Near her swung a tanker filled with aviation gas urgently needed in Malta, two hundred miles to the north. We paid

homage to their courage with compassionate respect, and wished they weren't there.

Toward the west, where the root of the mole curved and joined the low profile of the city, were anchored more freighters and a destroyer. A minesweeper that kept us company on the trip from Alex, *H.M.S.A.S. Treen,* lay to the south between us and the city seawall. Next to it, and closest of the Allied vessels, a small coaster swung on one hook. Closer still, in fancy camouflage and obviously badly battered, the Italian motorship *Agostino Bertani* held our speculative gaze with her Latin grace. Displaying her raked funnel, low superstructure and seductive sheer in the midst of our motley flotilla, she looked like a badly used Maserati surrounded by old family Fords. A pelagic queen. Through the glasses we could see blast damage, twisted steel and scorched paint, but she was riding evenly and to the casual glance looked ready to depart for Genoa, her port of registry. The embarkation gangway was stowed, but a rope ladder hung from the stern, probably because of the barrage balloon floating from a cable secured on the fantail. In legal jargon the *Bertani* constituted an "attractive nuisance," for seamen are traditionally fond of visiting anything floating nearby. Besides, we were positive Italian vessels were fitted with enormous wine lockers. We had to find a way to go aboard.

Following the nightly raids, the British army would send a launch around the harbor, stopping at each anchored ship to pick up any wounded, and a friendly corporal thought of a way a skiff could be managed. There was no sign he thought it curious that anyone would want to go punting among the debris and oil slicks floating around us, and his only comment was, "Mind you don't bump into something wicked." This referred to a report that the bombers were dropping a new harbor torpedo which knew better than to miss a target and then continue to pointless self-destruction on the beach. Failing to bag a ship promptly, it would run mad circles just under the surface until the fuel was exhausted, then a ballast tank filled and it would float tail down, barely submerged, and wait for the unwary. So we would row very carefully.

W7IDF and Paolo (identity concealed).

The next afternoon the engine department cadet and I climbed the rope ladder to the fantail of the *Bertani* and made our way along the main deck and up to the bridge. The damage was worse than we had guessed, but the R.A.F. had pounded the harbor before the fall of Tripoli and now the Germans were taking their turn, so it was a miracle the ship was still afloat. Debris blown back and forth by dozens of raids obstructed passageways, and everywhere were bent shards of steel plate and twisted and severed stanchions. Fire had gutted the chart room, wheelhouse and radio room, and one deck below a bomb had exploded immediately after penetrating the midship deckhouse. The blast had torn everything apart just aft of the stack and down through the engine room, but a fast fuse had spared the hull. The foredeck and afterdeck were holed but strong; if the *Bertani* survived the current series of raids she would probably end up as an oil barge. She had been a handsome ship, and the visit was depressing.

Returning aft to leave, we remembered the putative wine stores and found several undamaged storerooms at the bottom of a companionway from the main deck. It was getting late, but we opened one more door, and there they were. Five or six large wine casks in a heavy timber rack along a thwartship bulkhead, and they were empty. The number is dim in my memory, but I recall clearly that they were a light-colored wood, which surprised me, and there was a small table in front of them. On the table lay a neatly folded pair of German army trousers, and beside them a half-empty tin of English cigarettes. We eyed these with speculation, and the drained casks with regret. "Time we got back," I said, and we left.

Later, as we were sitting in the saloon and conscientiously testing what was left of a case of Scotch retrieved earlier from longshoremen who had pinched it from army stores taken aboard at Port Said, the captain returned from a meeting ashore with the depressing news that we couldn't go alongside and discharge for another day or two. "Never mind the days," the messman said, "it's the nights that give me fits." Captain Miller just nodded and muttered his favorite expletive, "Got them!" A stocky Finn who looked like a nice Hermann Goering with muscles instead of fat, he spoke infrequently and with a thick accent that left us mystified about the ethnic roots of his name. "Got them!" sufficed for most occasions that called for comment, and began or ended the sentences demanded by special circumstances. We were amused by the phrase until events certified it as eminently apposite. The crew respected him, and to me Miller was the ideal skipper: professionally expert, totally unflappable, reserved but approachable. His silent kindliness and courage were importantly supportive, and I was to regret I lacked the wit to find a way to tell him so.

With the news that our idle status would continue, my thoughts turned to something I had noticed in a corner of the *Bertani*'s shattered radio room. It appeared to be the remains of an FuG 16, the 38 to 43 MHz wireless used in German fighter aircraft. Wary exploration of riddled Messerschmitts abandoned on Castel Benito airfield just outside the city had turned up nothing worth carrying away. Shards of canopy Perspex for shaping into bug paddles, and still in use today, but no FuG 16 for conversion to ten meters. Also, I wondered who was living on a bombed-out freighter anchored at target

center.

Promptly at seven-thirty that evening, while cargo was being worked under a few lights on the jetty, the alarm went. Within minutes the dark edge of the city reflected the cracking white flashes of antiaircraft batteries along the breakwater, the thunderous red blooms planted by sticks of bombs, and then, in the dark heart of the harbor, a ballooning ball of yellow flame from a tiny coaster hit squarely amidships. Suddenly the raid was over, the convulsive thud and crash of explosives sucked instantly into a stunning silence. Slowly hearing recovered, and a familiar hissing rose from the water as spent shrapnel fell back from the sky, now and then rattling on our steel. After another minute there was only the distant sound of burning, and from the dark anchored shapes faint hails as the medical launch called for wounded. As they came alongside, we were saddened to learn that the matey crew of an antiaircraft battery had been wiped out, a singularly cheery and nerveless mob of Londoners who had found entertainment in teaching us cockney slang. They had called themselves "The Tophatters" and were perversely amused to hear that their painted insignia was identical to that displayed by a Staffel of 109s the Luftwaffe sent to Spain in 1937. Now they were gone. In the city, apartment buildings had been hit as usual, and the coaster between us and the *Bertani* was still smoking and low in the water. Preparing for a visit to the *Bertani*'s radio shack in the morning, I put together a thief's kit of side-cutters, screwdrivers and small wrenches.

The next day began chilly and clear, with a cloudless blue sky and a steady breeze. In the harbor the chop was low, but to seaward the spray rose regularly and fell sparkling on the breakwater. Inshore small puffs of spume floated up from the old gray seawall fronting the low bone-white profile of Tripoli's villas. I was still astonished that the Mediterranean could be so cold, even in midwinter. North Africa had been a surprise from the first: windy and raw at Alex, and then barren brown hills curving from Tobruk down to Benghazi. Wondering what the Afrika Korps thought of their palm tree insignia, I put on a heavy wool mackinaw and a watch cap, and I suppose that's why I met Paolo.

Before noon, but later than I had planned because I had listened to the sexy lady news announcer from Radio Sofia and her report, rather premature as it turned out, of a conclusive *Bestrafung* of Tripoli harbor, I was again aboard the *Bertani*, alone this time, with a bag of tools and, just in case, a bottle from our store of liberated Scotch. Everything looked the same as before, but somehow there was a subtle difference. Three hundred feet in the air the balloon weathervaned into a cold north wind, and three or four miles above it the daily photo plane was a tiny speck, returning home with negatives showing a small coaster still afloat but down by the stern and perhaps a crater where our cockney friends had nightly stood watch to protect us.

The battered box lying on the deck in the radio room was indeed an FuG 16, but it was in bad shape. Neither of the two bandswitches would budge, and a look at the back showed why they wouldn't. Apparently the deadlight blown from the porthole opposite had struck the rear panel and crushed the insides. No hope. Some earlier scrounger had better luck, judging from the vacant mounting brackets and empty spares lockers. Stubs of severed copper tubing protruded from the antenna lead-in bowl insulators, but a half dozen Pyrex standoffs had been left on one bulkhead. I was unscrewing one of these when I got a message that I wasn't alone and turned around.

Captain Miller.

In the doorway a young man of medium height was smiling at me. Dark curly hair, khaki sweater and pants. At first I assumed his motives were mine: curiosity and larceny. "Hi," I said, "somebody didn't leave us much." For a moment he just looked at my coat. Still smiling he said, "Buon giorno." Oh dear, I thought, The Enemy. "Buon giorno," I replied. "You speak English?" He shook his head. Why hadn't I studied my Italian phrase book? Only one sentence came to mind, and after a thoughtful pause I said, "Un biglietto per Milano, per favore." A ticket to Milan, please. He laughed and put out his hand. Amenity established, I removed my coat and from the game pocket carefully drew out the bottle of Scotch, wondering how many of Mussolini's finest were tucked away in the *Bertani*.

In an effort to communicate, we discovered common ground in German and Spanish, with Paolo favoring one and I the other, and in a loony patois we told each other who we were, traded souvenir recollections of life at home, and confided some of our hopes for the halcyon days of peace we foresaw with naive certainty. While we talked, I unscrewed the standoffs, and Paolo, an active ham for years and more lately a radio technician in the Italian army, applied himself expertly to the FuG 16 and filled my coat pockets with parts. Sensing my curiosity, he talked about his life before the war, pausing now and then to find the right phrase, silent at times for a minute or two when memories crowded and blocked the flow.

Paolo's father, a politically active civil servant, ardently Fascist, insisted that his son postpone his university studies and volunteer for service in Spain. That was in 1937, when Paolo was nineteen. Training was brief, with emphasis on parading, and he soon embarked for the Spanish Civil War with General Roatta's Black Flame Division. Before the year was out he was thoroughly disillusioned and when, during the Italian attack from Algora toward Guadalajara, a bomb fragment sent him home for recuperation and discharge, he thought himself lucky. Working again on his own equipment instead of military signals gear raised his spirits;

The Agostino Bertani.

soon he was fit and bearing down hard on electrical engineering texts. He recalled this as "the happiest time of my life." It was a short reprieve. Putting Franco in power had been an easy first step, and soon German boots were marching through one country after another. The Italian army told Paolo his technical skills were very highly regarded and issued him a new uniform. He was grateful to miss out on Mussolini's glorious calamities in Albania and Greece, but those defeats guaranteed him a ticket to Tripoli. The Germans, appalled by the Italian fiasco in Greece, moved in swiftly, and their success drew a gallant but sacrificial counterattack by a British expeditionary force from Egypt, critically draining an army which had just chased the Italians back across the Western Desert. To exploit this weakness the Germans promptly invested armor in North Africa, and soon the Afrika Korps was leading a revitalized Italian army toward the Nile. Paolo would spend more than a year nursing its radios.

His first assignment was months of easy depot duty at Tripoli, thanks to the German he had learned in Spain, but in the summer of 1941 Rommel pressed hard against the British and Paolo was posted to the Ariete Armored Division and the delights of front line maintenance of poor radio equipment in obsolete M.13 tanks. There were about a hundred and fifty of these and many of them weren't fitted with radios, but this made it all the more important that in those that had them the radios worked. Keeping the mobile gear operational in spite of the dust, heat, concussion and constant vibration was a maddening task.

Paolo's stories of equipment failure, troubleshooting and repair soon brought up the subject of ham gear and our personal preferences and experiences. We argued the advantages of our favorite antennas and agreed that CW was far more satisfying than phone. Before long we were comparing DX notes, recalling more or less accurately the best of the miracles recorded in our logbooks at home, and in cordial competition modestly attributing our feats to luck rather than technical prowess. Paolo scored heavily when he mentioned that his first West Coast contact was W7CSF. The call has been reissued but my good friend Dick Rose held it then, and I remembered clearly his announcing one evening that he had just worked the first Italian he had ever heard. Probably I responded with rude noises indicating disbelief, and I could foresee his smile when I confirmed the contact with a report of this meeting. I didn't tell Paolo Dick had never received his QSL.

Suddenly I realized that the sunlight from the porthole had moved from the deck into the passageway, and it was time to leave. Paolo had volunteered nothing about his present circumstances, and as I collected my tools, I tried without success to think of tactful questions. We shook hands and he asked me if I would come back the next day. I said I would. Together we made our way through the battered passage, but Paolo wouldn't come out on the open afterdeck, and as I left him I asked if he needed anything. He shrugged and smiled. "I have food," he said.

There was hardly a ripple on the water. As I rowed I kept the transom centered on a tall palm behind the seawall, where peddlers hawked triangular paper packets of dates and almonds. The late sun on the low white buildings made sharp silhouettes of the trees – a travel poster view of friendly Tripoli. Halfway back I was pleased to retrieve two floating empty bottles as a present for my corporal friend who had asked if we had any on his first visit to the *Everett*. The Afrika Korps had charitably left behind an impressive stock of German hops and Hungarian barley at the Oea brewery (Oea was the old name of Tripoli), but bottles were in short supply and everyone was on the alert for empties. Minutes after I boarded the *Everett*, the gunnery officer knocked on my door and spotted the empty bottles. He hadn't believed my report of the empty wine casks on the *Bertani*, but something else was on his mind. "Churchill sent his apologies," he said, "and they'll take our tanks off tomorrow."

That night the Luftwaffe ignored us and the following morning the Crusader engines were roaring and backfiring in the holds, ready to go as soon as they were landed and the bridles freed. It was noisy and exiting but I left early, allowing for the longer trip from the breakwater against a low chop in the harbor. The wind had shifted and there was a suggestive haze in the southern sky. Torrents of rain and rotten visibility would be nice, I thought, rowing steadily, my feet pushing against a carton packed with old copies of *"QST,"* British ration "V" cigarettes, a flashlight and a box of spare batteries. In memory of the *Bertani's* vanished wine stores there were two bottles of vile Australian sherry.

Paolo was waiting for me in the radio shack, obviously pleased to have company again. It struck me that he was impressively neat and clean and his manner rather blithe and easy for a lonely fugitive, truant from a retreating army. In your shoes, I thought, I'd be wary and glum and look very scrubby. Stacking the magazines on the deck, I put the flashlight and batteries next to them and held up one of the bottles of wine. "For emergency use only," I said, thinking of his Italian palate. "Thank you very much," Paolo said, dismissing my deference with a smile. Opening one of the cigarette packs, he took two out, and after we lighted them he brought a small bundle from a corner of the room. Turning back a fold of canvas he handed me an Italian helmet. Inside was a Beretta automatic, and on top of it a British pound note. "For the emergencies," he laughed, and turned the note over to show me the back was covered with Arabic. "German counterfeit. Propaganda. It says here that the word of England is as good as this money, but I am very sure that they will both

be worth more, pretty soon, when this war is over." "Agreed," I replied, "Unless the English try exporting this tobacco."

I thanked Paolo for his gifts, and, after a brief explanation of Beretta design, disassembly and cleaning, he withdrew to silent concentration on the circuits and advertisements in the magazines. I fiddled with the gun for a while, but then my curiosity overcame qualms about prying and I asked him why he was waiting out the war in the center of a harbor where a night without a raid was an exception. He kept flipping the pages and smiled without looking up. The antiaircraft fire was so intense, he said, that hits on shipping were unlikely. The center of the target was the best place to be and the worst was the outside ring, from the jetties into the harbor side of the city. The latter was believable; during every raid we saw bombs bursting among the apartment and office buildings, and there were piles of rubble along the main streets, gaps and debris where there had been villas and shops, and every afternoon at four or five o'clock a flow of people into the countryside where those who couldn't find shelter slept in the fields. But the safety of the harbor center was relative and poor consolation, and Paolo's reply hadn't answered my question. He put down the magazine and gravely inspected the flashlight. Long minutes of silence. Sadness touched his face and I regretted my curiosity.

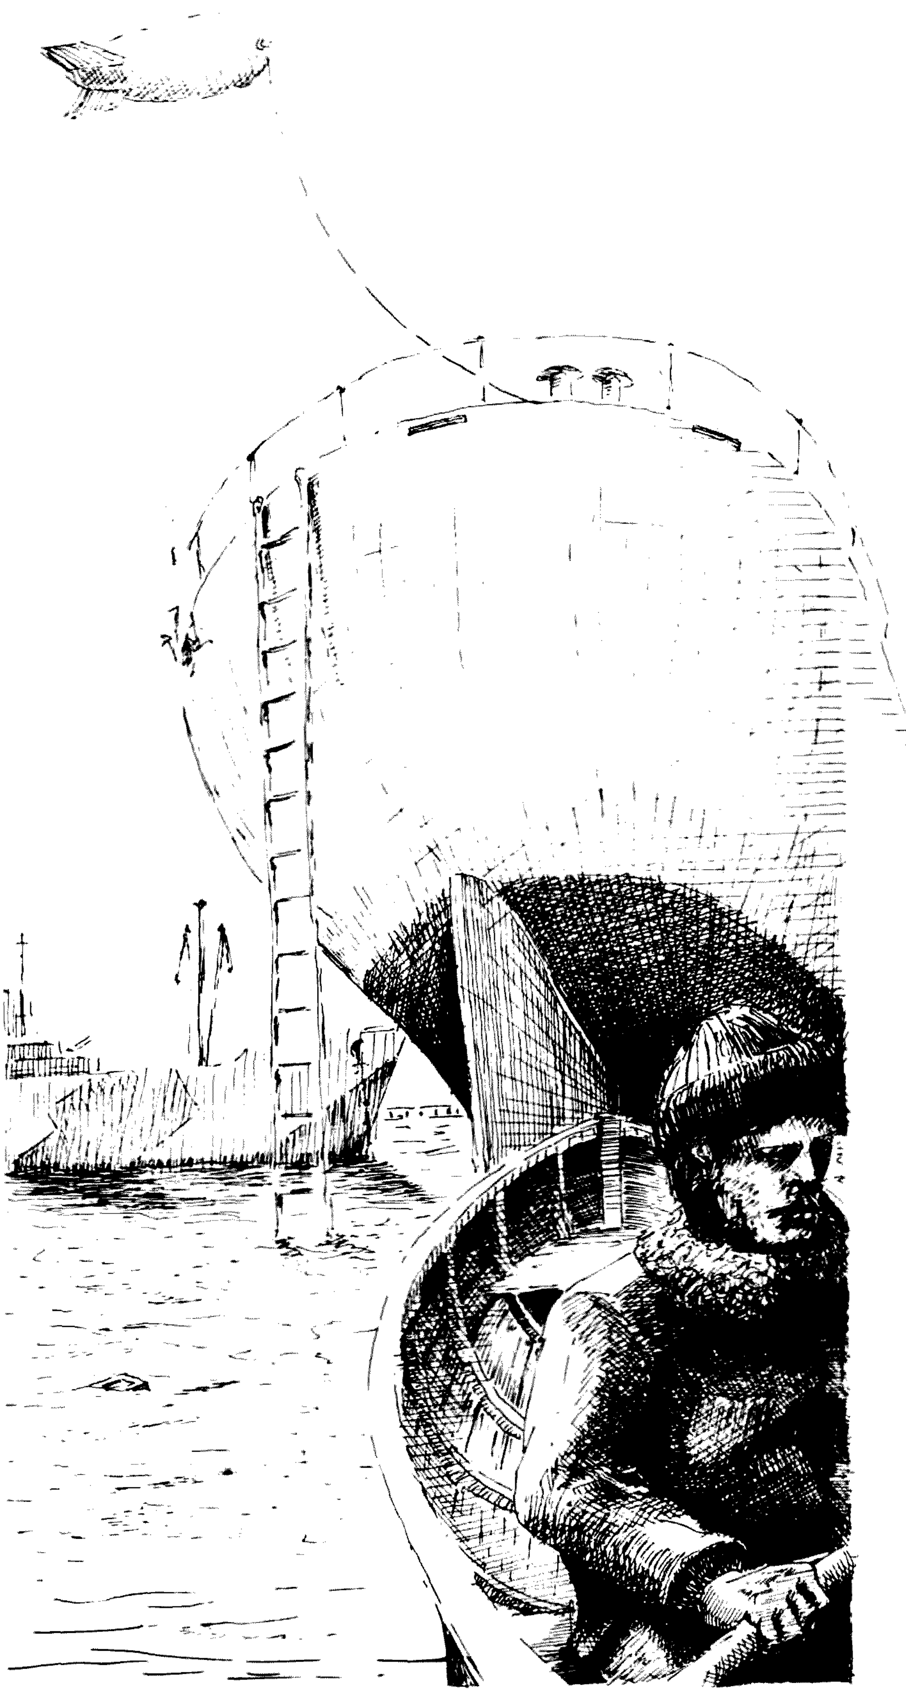
"Spain," he said, speaking very slowly, "was reality, and we had been prepared for it with lies. Germans fought Germans there, and Italians fought Italians. It was a bad time, and we understood nothing. Afterward, in the engineering school, I was just glad to study and not think about politics. Then, in 1940, suddenly Italy was in the war. Many people, like my father, said Mussolini acted to protect us from Hitler because France and England betrayed us during the Austrian Anschluss. They told each other that the fighting would soon be over, that Germany already had all of Europe except Italy, and that it would be our turn next if we didn't agree to a military alliance. Our first easy victories here in Africa left us foolishly optimistic, but before long the English pushed us back, things got very bad quickly, and defeat was close. We were ready to give up when the Germans arrived in February of '41, here in Tripoli. Now they are gone and I think it will soon be over."

Paolo stood up, stared out the porthole for a moment and lit another cigarette. "I am talking too much." I said nothing. "Rommel was too much for the English, but he should have been here in the beginning. Even before El Alamein I knew we would have to turn back. Supplies weren't getting through from Italy. The sinkings were increasing at the same time that Montgomery was getting more and more through Suez from America. Marshal Cavallero kept promising that fuel for the tanks would arrive immediately, but we knew he was lying. Less and less got through. It was hopeless."

During one of Rommel's efforts to stiffen Axis morale by mixing Panzer units with the Italian regiments, Paolo's combination of language and technical skills were noted and he found himself in a liaison assignment untying communication knots. Access to all Italian and German radio nets confirmed his feeling that disaster was inevitable.

"After Alamein," he continued, "I stayed with the 15th Panzer. There wasn't nearly enough transport for the retreat, so I rode with the Germans. Otherwise, I would have been in the bag and spent the rest of the war in a stockade in Egypt. I knew if I got back to Tripoli my friends here would help me."

Rommel hardly slowed for Tripoli. At Castel Benito, Paolo walked away from the war. He unbuttoned a shirt pocket, drew out a leather folder and opened it to show me a picture of a very pretty dark-haired girl standing with him in the Piazza Italia. She was wearing a white dress and smiling at the sun dial on the wall of Tripoli Castle. "I'm going to stay here," Paolo said. "We are going to be married some day. When I came here from Italy I was billeted with Antonia's parents, and now they are helping me as much as they can. An English civil administration officer is living in the room I had, and he brings



them extra food for me."

"She is very attractive," I said. "I hope everything goes well." I carefully printed my name and address on a scrap of cardboard and held it out. "When you can, write to me about the wedding."

"I promise," he said. "Soon now, the planes will be bombing Sfax instead of Tripoli, and it will be quiet here. Then the Germans will be defeated in Tunisia and the war in Africa will be over. It won't be long."

"And then?" I asked.

"Then the Mediterranean will belong to the English navy. Italy will surrender, and before long," Paolo smiled, "Antonia and I will be living on a small farm outside Tripoli."

"What do you know about farming? I thought you grew up in a city."

"I lived in a city, but I grew up in Spain and Africa." He shrugged his shoulders. "Anyway, Italians are all good farmers. Good builders and good farmers."

Years later I recalled Paolo's remark as I read of a letter Rommel wrote to his son, Manfred. Referring to the Italians, he said, "Certainly they are no good at war, but one must not judge everyone in the world only by his qualities as a soldier – otherwise we would have no civilization."

"Goodbye, Paolo," I said. "We may leave tomorrow. Good luck, and don't forget to write. When we're on the air again we'll arrange a schedule."

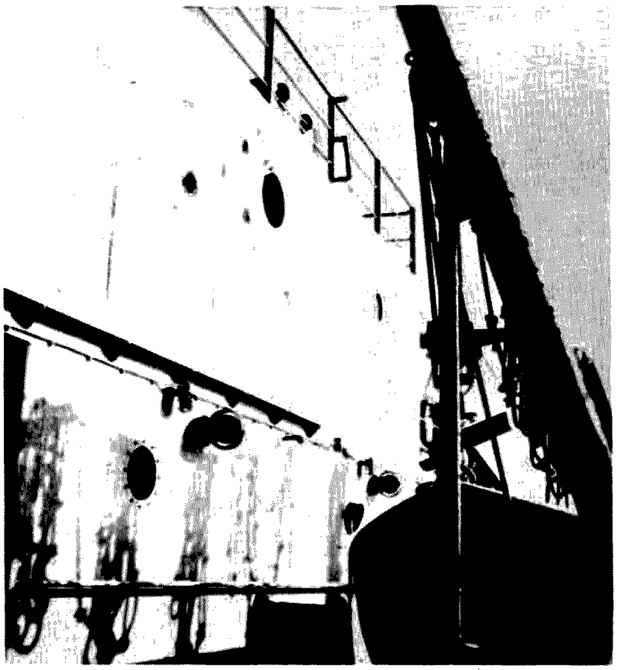
"Of course! With a farm there is plenty of room for antennas, you know." He was silent for a minute. "That is in the future. Today I am a deserter from the Italian army in time of war; I am engaged to a Jewish girl and being fed by an enemy officer while I wait for my country to surrender. I wonder what my father would think. Well, this will soon be over. Now, goodbye."

He waited in the shadow at the end of the passageway

until I waved from the stern and climbed down the ladder. As I rowed away, I wondered why Paolo hadn't found a safer place to await the surrender he expected in a few months (seven, it turned out), but I thought I knew. There were many Italians still in the area, but they were not men of military age or inclination. They were middle class, middle-aged or older, merchants and colonial farmers. They weren't on the streets much during the week, but leaving the Cattedrale di Sacro Cuore after Sunday morning mass they were surprisingly cheery, friendly, quite willing to converse with the strangers who had taken over their city. With unexpected candor, some would even defend Mussolini, insisting that he had been deceived by his ministers, and most agreed that the best chance for a happy solution lay with Prince Umberto and the diplomat Dino Grandi. And at some point in every conversation the lament would be repeated: "If only Marshal Italo Balbo were still alive!" In defeat, their fervent nationalism was as important as the fat on a hibernating bear. We listened to them with surprise, and then with dismay and a certain uneasiness. No, I didn't think that Paolo, a deserter, could have found much compassion in them. Probably they would promptly have turned him in and with relish sent the bad news to his family.

As I boarded the *Everett*, the last of our Crusaders was ashore, and the booms were being topped. The hatch covers dropping into place between the strongbacks made a very pleasant noise, rather like a gangway lowered smartly to the dock in some neutral port ablaze with nightclubs. The pretty balloon I was inflating promptly was pricked by a news bulletin from the deck cadet, and I went into the saloon for coffee and sympathy. The messman was humming "Sheik of Araby" and wiping the tables with special flourishes. "My prayers have been answered," he said. "One more night on the hook and tomorrow back to the fleshpots of Egypt!" "Well," I said, "you didn't pray hard enough. The latest word is a quick turnaround at Alex and back to Sfax with a full load of cased gas." He whimpered plaintively and lifted a corner of his apron to his eyes. "Boo hoo, and I'll never see my dear family again." Bathos was acceptable. "My hearfelt congratulations," I said. He poured our coffee and we sat in silence. I was thinking that I still wouldn't want to trade places with Paolo.

When we had pulled out and anchored again near the *Treen*, there was an hour of winter daylight left. We expected a visit from Sicily at the regular time, and perhaps a little something extra saved for us from last night's break in the routine. With this in mind, I went into the wheelhouse to experiment with an aircraft warning device H.M. Signals had installed during a shuttle to Beirut for the Ministry of Sea Transport when the area was being harassed by planes from Crete. We had heard about radar, of course, and observation of the bedspring antennas on battleships and cruisers gave us a clue to the frequencies, but we couldn't guess the secret of generating power pulses adequate to provide useful reflections from targets at fifty or a hundred miles. The magnetron was an enigma well-guarded. And the Royal Navy desperately needed more radar, so none was allotted to merchant ships; however, a British Marconi had come up with a jury rig warning system. In essence this consisted of a tuned amplifier driving an alarm bell noisy enough to alert any pilots who hadn't already spotted us, fed by two masthead microphones separated by an acoustical baffle. Theoretically, shipboard noise was



The near miss at Miller's porthole. Note hole in lifeboat bow.

picked up by both mikes and canceled, leaving only the bad news to excite the amplifier. The passband was narrow and tuned, according to the skeptical, to guttural German. The optimistic among us assumed the peaking frequency had something to do with audio quality common to BMW, Daimler-Benz, Jumo and Gnome-Rhone engines. In fact, the only time it went off was when the saloon messman climbed atop the wheelhouse and blew patiently into a beer bottle. He was promised that a second demonstration would ensure his disappearance at sea.

Now it was dark. The sun had set after a brief pink illumination of thin webs spun high overhead by a slow shifting of upper winds. I could sense prayers for cloud cover rising like smoke in the still surface air. Cargo was being worked on a ship already secured in the berth we had left, and bright lights along the mole silhouetted the *Empire Voyager*, still at anchor, low in the water and showing no lights. In the southern sky stars glittered, but none were visible to the north; there was a light drizzle and I wondered if the weather people on Sicily were forecasting a low ceiling at Tripoli.

There was no warning. A Ju88 appeared over the breakwater, framed by the Voyager's masts, cannon and machine guns winking orange and yellow. Then there were three more, wingtip to wingtip, and bombs were already bursting ashore and in the water as I ran for shelter, portside and down the ladder. At once there was a furious rattling as bullets raked the *Everett*, along with a sharp bang when a 20mm shell exploded against the concrete facing outside the captain's quarters, missing his porthole by inches. From the breakwater around the harbor and on into the city, bomb hits glowed red at neatly spaced intervals, and as the storm of noise died away, fire bloomed from a small vessel on our starboard bow. A quick check indicated we had only superficial damage from gunfire, and none of the bomb explosions in the harbor had been close enough to hurt the hull. Even in the dark it was obvious that we came close to qualifying as bullet-riddled. Perforations in

Tripoli: night raid.

the deck ventilators were back-lighted rubies, and from inside the holds the starboard side looked like a planetarium, but most of the hits were high. Ahead lay a painstaking survey of all the running gear; it wouldn't do for a nicked winch runner to drop a tank down a hatch. Luckily, no one had been on deck on the wrong side, but a visitor from another ship had a leg wound from a ricochet that entered a passageway, and I had steel splinters in one knee. The *Bertani* wasn't visible and I hoped Paolo had been below, shining his flashlight on a magazine.

After a short coffee session in the saloon, the messman was clearing away the cups and we were alone. "Got them!" he said, quoting the captain. "The old man thinks those brave lads must have flown right on the water for the last fifty miles. He said they probably had orders to light a beacon here and we'll get it again in a few minutes." I agreed. It was the first really low level attack since our arrival and, in view of the drizzle and broken ceiling, probably a pathfinder.

Returning to my room, I paused on the boat deck to listen. As the wavering beat of distant engines rapidly grew louder, narrow white searchlight beams flicked on, one after another, from among the fires ashore. This time the antiaircraft gunners were ready, and suddenly all batteries were firing, white flashes lighting up the harbor crescent from the mole to the city. Immediately bombs hit a destroyer and a tanker west of us, and a plane ablaze went into the water just beyond the *Bertani*. Overhead, white in the probing searchlights, bombers seemed to hang in the sky, unconcerned and irrelevant to the turmoil below. Our 20mm Oerlikons, which with a minute's warning might have scored against the first low attack, were useless now, but a sharp crack from the three inch gun on the bow told us that events had exhausted its crew's patience with the harbor rule that merchant ships were not to fire without orders. The battle phone circuit forward was dead, later found to be shorted by a pin through the cable, and the Navy gun crew was firing as fast as it could reload.

Aboard the Bertani.

Burning gasoline and oil had spread over perhaps a third of the harbor, when another flight of bombers came over. The crashing, thudding and jarring increased in intensity. A ship near the breakwater was hit bow and stern, and a burning plane broke up against a salvage vessel near the harbor gate. Our clothes were whipped by concussion as we stared at the *Empire Voyager* – eight thousand tons of explosives aboard and she was on fire. On our other side a Liberty, the *Sam Parker*, slowly moved through the smoke between us and the *Bertaini*, headed for the harbor gate and open sea. Soon other ships, backlighted by fires and then hidden by smoke, were making their way carefully out of the harbor. The antiaircraft guns stopped firing, gun by gun, but explosions continued around us and orange tracers arced away from the *Voyager* as heat set off ammunition on deck. She was aflame from stem to stern.

I had just left the port wing of the bridge for my room to get a flashlight, with some idea of blinking it at Paolo, when the *Voyager* exploded. A brilliant orange flash lighted the passageway and our ship lifted, trembled and fell back, rolling to port and then righting. The sound was something more than noise, a tremendous sharp thud that made my head hurt and left me deaf for a moment. Then a mixture of sounds – everything that could move was clattering, knocking against something else. After a bit, I ventured out on the boatdeck. Debris was hissing into the water and rattling onto the decks, and now and then a heavy piece from the *Voyager* rang on our steel. The air was filled with muck blown up from the bottom of the harbor, but soon it cleared and in the glow from burning oil I could see the *Bertani* was still afloat. Poor Paolo, I thought; you could be in a nice safe POW camp at Ismailia with a view of the canal.

The rest of the night was spent collecting our wits, drinking coffee and checking for serious damage. Below the waterline the hull was whole, but the oil burning where the *Voyager* had been showed our starboard side to be well scarred. The decks were littered with iron from the sky, and coated with slime from the bottom of the harbor. Dents showed where heavy pieces had struck and bounced over the side; the gun tubs were badly chewed and one lifeboat was holed,

but all the wounds we found were superficial. "Got them!" the captain muttered, meaning he was mystified by our good fortune, and so were we all.

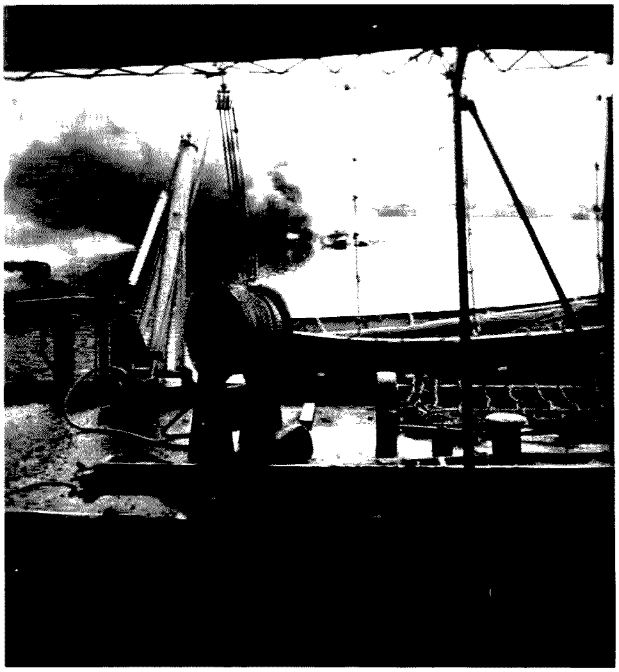
It was nearly dawn when orders were brought aboard for departure for Port Said, and I tried again to raise Paolo with the light. I had decided that if I saw no blinking reply the possibility that Paolo was hurt and needed aid would justify confiding in the corporal. Minutes passed and no luck. The launch would be leaving soon. I had just about given up when the answer came: "OK OK OK god luck god luck." The misspelling struck me as inspired.

Hurrying with our last bottle of Scotch, I caught the corporal at the ladder as he was telling the captain that one of the *Voyager*'s boilers had flown over the city and come to earth in the suburbs, and one of her guns had dropped onto the salvage ship at the harbor gate. "Got them!" Miller said, rubbing his nose thoughtfully. "Ta," the corporal smiled as he took the bottle, "come again soon."

The wind was picking up from the north, sweeping away the clouds and fanning fires around the harbor, and the first gray light revealed that the *Bertani*'s barrage balloon had pulled free during the night. I thought of its passage, a spectral mystery in the sky blocking out the stars as it sailed noiselessly over the Sahara, and then in the sunshine a delight to the Tuaregs who would turn it into tents and a fable.

In a couple of hours we were under way, leaving behind us a dispiriting scene. The destroyer had been beached and lay at a sad angle near the seawall; near it spray rose now and then, as demolition crews exploded torpedoes or mines; oil slicks were still burning on the water and streamers of black smoke drifted into the city. As we moved slowly past the *Bertani*, her lines again drew our admiration. She was still riding evenly, but the foremast was canted aft at a new angle, a bit rakish but not really inappropriate. From a wing of the bridge I waved goodbye.

Soon Tripoli was just a line on the horizon. It could have been Boston or Sydney.■



Unidentified remains.

WHAT HAVE YOU MISSED?

The back issues of 73 are a gold mine of interesting articles . . . just take a look at what's been covered . . . every possible interest. This is the most important library you can have for hamming.

The supply of these back issues is very limited . . . and when these are gone, that will be it. Don't miss out by procrastinating.

Single issues . . . . $1 each (before 1976)
Ten back issues (your choice) . . . . . $12 postpaid in US.
Twenty-five back issues (your choice) $20 postpaid in US.
Twenty-five back issues (our choice) $10 postpaid in US.

JUNE 63. Surplus Issue: DMQ-2 Beacon Tx on 220, increasing ARC-2 transceiver selectivity, PE-97A pwr supply conversion, BC-348 bandspread, inductance tester, converting BC-230 tx, beginner's rx using BC-453, recvr motor-tuning, transistor cw monitor, BC-442 ant relay conversion, mobile loading coils, increasing Two-er selectivity, TV with the ART-26 tx, TRC-8 rx on 220, ARC-5 hf rx & tx, ARC-3 tx on 2M.

AUG 63. Battery-op 6M stn, diode noise gen, video modulation, magic T-R switch, ant gain, halo mods, cw breakin, VEE beam design, coax losses, RF wattmeter, TX Tube Guide, diode pwr supply, "Lunchbox" squelch, SWR explanation, vertical ant info, info on Windom ant.

OCT 63. WBFM transceiver ideas, HF propagation, cheap fone patch, remote-tuned Yagi, construction hints, ant coupler, $5 Vertical, filament xformer construction, 2M nuvistor converter, Lafayette HE-35 mods, Buyer's Guide to Rx & Tx, product detector, novel Hi-C VFO, radio astronomy, panadaptor "if" converter, compact mike amp.

FEB 64. 2M multichannel exciter, rx design ideas, majic t/r switch, loudspeaker enclosures, 40M 2W tx, look at test equipment, radio grounds, 40M ZL Special ant, neutralization.

MAY 67. Quad Issue: 432 Quad-quad-quad, expanded HF quad, Two el quad, miniquad, 40M quad, quad experiments, half-quad, three el quad, 20M quad, tiltover quad, easy-to-erect quad, Quad Bibliography, FET vfo, tube troubleshooting, HF dummy load, understanding "dB," HF SSB/cw rx, geometric circuit design, GSB-201 transceive, FET converter for 10-20M, hi-pass rx filters.

JULY 67. VE ham radio, VE0 hams, dsb adaptor, home brew tower, transistor design, '39 World's Fair, gnd plane ant, G4ZU beam, SSTV monitor, UHF FET preamps, IC "if" strip, vertical ant, VHF/UHF dipper, tower hints, scope monitoring, operating desk, S-Line crossband, hi-school ham club, Heath HR 10 mods.

OCT 67. HF solid state rx, rugged rotator, designing slug-tuned coils, FET converter, SSTV pix gen, VHF log-periodics, rotatable dipole, gamma-match cap, old-time dxing, modern dxing.

JUNE 68. Surplus Issue: Transformer tricks, BC-1206 rx, APS-13 ATV tx, low voltage dc supply, surplus scopes, FM rig commercial xtal types, Wilcox F-3 rx, restoring old equipment, 75A1 rx mods, TRA-19 on 432, freq counter uses, transceiver pwr supply, uses for cheap tape recorders, Surplus Conversion Bibliography, RT-209 walkie on 2M, ARC-1 guard rx, RTTY tx TU.

JULY 68. Wooden tower construction, tiltover towers, erecting a telephone pole, IC AF osc, "dB" explained, ham club tips (Part 1).

SEPT 68. Mobile vhf, 432 FET preamps, converting TV Tuners, xtal osc stability, parallel-Tee design, moonbounce rhombic, 6M xciter (corrections Jan 69), 6M transceiver (corrections Jan 69), 2M dsb amp, ham club tips (Part 3).

NOV 68. SSB xtal filters, solid state troubleshooting, IC freq counter (many errors & omissions), "cv" transformers, space comm odyssey, pulsar info, thin-wire ants, 40M transistor cw tx/rx, BC-348M double conversion, multifunction tester, copper wire specs, thermistor applications, hi-voltage transistor list, ham club tips (Part 5).

JAN 69. Suppressor compressor, HW-12 on 160, beam tuning, AC voltage control, 2M transistor tx, LC power reducer, spectrum analysis info, 6M transistor rx, operating console, RTTY autostart, calculating osc stability, lo-pwr 40 cw tx, sequential relay switching, sightless operator's bridge, ham club tips (Part 7).

FEB 69. SSTV camera mod for fast-scan, tri-band linear, selective af filter, unijunction transistor info, Nikola Tesla biography, mobile installation hints, extra-class license study (Part 1).

MAR 69. Surplus issue: TCS tx mods, cheap compressor/amp, RXZ calculations, transistor keyer, better balanced modulator, transistor oscillators, using blowers, halfwave feedline info, Surplus Conversion Bibliography, extra license study (Part 2).

APR 69. 2-channel scope amp, rx preamp, Two-er PTT, variable DC load, SWR bridge, 100 kHz marker gens, some transistor specs, SB-610 monitorscope mods, portable 6M AM tx, 2M converter, extra license study (Part 3).

MAY 69. 2M Turnstile, 2M Slot, rx attenuator, generator filter, short VEE, quad tuning, using antennascope, measuring ant gain, phone patch regs, SWR indicator, 160M short verticals, 15M antenna, HF propagation angles, FSK exciter, KW summy load, hi-power linear, extra license study (part 4), all band curtain array.

JUNE 69. Microwave pwr generation, 6M ssb tx, 432-er tx/rx, 6M converter, 2M 5/8 wave whip, UHF tv tuners, ATV video modulator, UHF FET preamps, RTTY monitorscope, extra license study (part 5), building uhf cavities, mini-VEE for 10-20M, vhf vfo.

JULY 69. AM modulator, SSTV sig gen, 6M kw linear, 432 KW amp, 432-er tx/rx, 6M IC converter, radio-controlled models, RTTY IC TU, audio notch filter, VRC-19 conversion, tube substitution, 2M transistor xciter, extra license study (part 6), hf FET vfo.

AUG 69. FET regen for 3.5 MHz up, FM crystal switching, 5/8 wave vertical, introduction to ICs, RTTY tone gen, good/bad transistor checker, 2M AM tx, measure transistor Ft, 160M propagation, triac applications, simple IF sweep gen, transistor keyer, SB-100 on 6M, xtal freq measurement, extra license study (part 7), FM deviation meter, qrp am 6M tx, circular quads, FM noise figure, transistor parameter tracer.

SEPT 69. Tunnel diode theory, majic tee, soldering techniques, wave travel theory, cable shielding, transistor theory, AM noise limiter, AFSK gen, transistor amp debugging, measure meter resistance, diode-stack pwr supply, transistor testing, 2½W 6M tx, HX-10 neutralizing, capacitor useage, radio propagation, AM mod percentage, extra class license study (part 8), 3-400Z linear, ATV vidicon camera, 2 transistor testers, FET compressor, rf plate choke.

OCT 69. Super gain 40M ant, FET chirper, telephone info, scope calibrator, thyrector surge protector, slower tuning rates, identify calibrator harmonics, FM adaptor for AM tx, CB sets on 6M, proportional control xtal oven, xtal filter installation, Q-multiplier, transceiver pwr supply, extra class study (part 9).

NOV 69. NCX-3 on 6M, IF notch filters, dial calibration, HW32A external VFO, 6M converter, feedline info, rf z-bridge, fm mobile hints, umbrella ant, 432-er tx (part 1), pwr supply tricks with diodes, transistor keyer, transistor bias design, xtal vhf sign gen, electronic variac, SB33 mods, extra class study (part 10), SB34 linear improvements.

DEC 69. Transistor-diode checker, dummy load/attenuator, tuned filter chokes, bandswitching Swan 250 & TV-2, 88mh selectivity, match exercizes, rtl xtal calibrator, transistor pa design, hv mobile p.s., 1-10 gHz freqmeter, CB rig on 6M, extra license study (part 11), 1970 buyer's guide.

JAN 70. Transceiver accessory unit, bench power supply, SSTV color method, base-tuned center-loaded ant, 6M bandpass filter, extra license study (part 12, rectifier diode usage, facsimile info.

FEB 70. 18-inch 15M dipole, 6M converter, high-density pc board, camper-mobile hints, 2M freq synthesizer, encoding/decoding for repeaters, DX-35 mods, panoramic vhf rx, variable-Z HF mobile mount, extra license study (part 13), linear IC info, qrp 40M tx, IC Q-multiplier.

MAR 70. Gdo applications, charger for drycells, FM freq meter, pc board construction, ham tm standards, cheap rf wattmeter, multifreq fm osc, "IF" system modules (part 1), Six-er mods, gdo dip lite, Motorola 41V conversion, cw monitor, buying surplus logic, SSQ-23A sonobuoy conversion, GRC-9 rx/tx conversion, extra class study (part 14), intro to vhf fm.

APR 70. Noise blanker, 2M hotcarrier diode converter, repeater controller, understanding COR repeater, 7/8-wave 2M ant, extra class study (part 15), inexpensive semiconductors, removating surplus meters, linear amp bias regulator, hi performance if amp & agc system, SSB bfo for shortwave radio, vacuum tube load box, general fm dope & repeater guide, meggering your ant.

MAY 70. Comments on "fm docket" #18803, future of cw, fm-am rx aligner, 5/8-wave verticals, using 2M intelligently, auto burglar alarms, pwr supplies from surplus components, "IF" system modules (part 2), vhf FET preamps, educated "idiot" lites, postage-stamp 6M tx, extra class study (part 16), Bishop IFNL, low-band police monitor, mobile cw tx, Wichita auto patch.

JUNE 70. DDRR ant, vfo circuit, remote SWR indicator, indoor hf vertical, two rx on one antenna, environment & coax loss, 2-el trap verticals, buying surplus, two 40M qrp tx, 21dB 2M beam, extra class study (part 17).

DEC 70. Solid-state vhf exciter, delta fre control for SSB, 2M transistor FM tx, HW100 offset tuning, "little gate" dipper, 3-500Z hf linear, general class study (part 5), "transi-test" (no good — errors!), transistor p.s. current limiter.

JAN 71. Split fones for dxing, Heath Ten-er mods, cw duty cycle, repeater zero-beater, HEP IC projects, 10-15-20M parabolic ideas, lightning protection, IC rx accessory, attic ants, double-balanced mixers, permanent marker tool, ham license study questions.

FEB 71. Metal locator, varactor theory, AFSK unit, SSTV patch box, ATV hints, RTTY tuning indicator, tone encoder/decoder, 220 MHz converter, SSTV magnetic deflection, IC code osc, 6M tx beeper, general class study (part 6), RTTY intro, perf-board terminal, low-ohmmeter.

MAR 71. IC audio filter, IC 6M converter, trap vertical ideas, digi counter info, surplus equipment identification, hf linear, simple fone patch, repeater audio mixer, digi RTTY accessories, coathanger gndplane, general class study (part 7).

APR 71. Intro to fm, noise blanker, repeater problems, Motorola HT mods, microwave repeater linking, digital ID unit, tuneable 2M fm rx/tx, repeater directory, fm marketplace, meter evaluator, varactor modulator, simple sig gen, touchtone hookup, hf preselector, 10M 12W tx.

MAY 71. 75M mobile whip, 2M preamp, transistor amp design, 10M dsb tx, portable fm transceiver directory, audio compressor-clipper, transistor LM freqmeter, 450 MHz link tx, simple af filter, 1-tube 2M transceiver, surplus 2M power amp, general class study (part 8)

JUNE 71. 2M beam experiments, 3 el 2M quad, multi-band dipole patterns, weather balloon vertical, pocket-pager squelch, two-er vfo, tuning mobile whips, transistor pwr supply, capacity decade box, 40M gain ant, general class study (part 9).

JULY 71. IC audio processor, audio sig gen, cw filter, 2M fm osc, 2M collinear vertical, FM supplier directory, Motorola G-strip conversion, transistor beta tester, general class study (part 10).

AUG 71. Ham facsimile (part 1), 500 Watt linear, dimensions for July collinear, 4-tube 80/40 station, vfo digi readout, Jupiter on 15M, general class study (part 11), pink ticket wave-meter.

SEPT 71. Transformerless power supplies, solid state tv camera, IC substitution, two rf wattmeters, IC compressor-agc, multichannel HT-200, ham facsimile (part 2), causes of manmade noise, vfo with tracking mixer, general class study (part 12), transistor heat-sinking, IC pulse gen, fone-patch isolation, hcd wattmeters.

OCT 71. Emergency repeater cor, transceiver power supply, predicting meteor showers, digi switching, reverse-current battery charger, passive repeaters, earth grounds, audio "tailoring" filters, Swan 350 mods.

NOV 71. 3-el 75M beam, motor-tuned gnd-plane, 2M gain vertical, transistor biasing, split-site repeater, fox-hunting, audio filter, transistor/diode tester, xtal tester, 6M kw amp, 10-15-20M quad, transistor pi-net final, ant feedline, communications dbs, 2300 MHz exciter.

AUG 72. SSTV intro, speech processor, fm repeater info, test probe construction, GE progline ac supply, 432 rf testing, preamp compressor, Six-er mods, fone patch, Two-er info, solar info, SCR regulator for HVPS, "ideal" xtal osc, fm rx adaptor, auto theft alarm.

SEPT 72. Plumbicon tv camera, WWVB 60 kHz rx, cigartube sig gen, cw active filter, rf testing at 1296-3500 GHz, balun ant feed, transistor power supply, IC 6M rx, IC fm/am detector (part 2), active filter design (part 3), K2OAW freq counter (part 3), 2M freq synthesizer (part 1).

OCT 72. Corrections for Aug. fm rx adaptor, 2M freq synthesizer (part 2), 6M transistor vfo, nano-ampere meter, time-freq measurement (part 1), active filter design (part 4), repeater timer, extra-class Q&A (part 3), balloon vertical, ID gen, time delay relay, 432 filter ideas, DC-AC inverter, hc-diode converter, rtl decade and nixie driver, plus-minus supply for ICs.

NOV 72. Hf transistor power amps, RTTY selcal, IC trf rx, transistor keyer, emergency power, 220 MHz preamp, double-delta ant, simple converter using modules, hf RF tester, "lumped line" osc, 2M freq synthesizer (part 3), K2OAW counter errata, 2M preamp, extra class Q&A (part 4), hi-Z voltmeter, Nikola Tesla story, vhf swr meter, transistor regen rx, 432 SSB transverter, AC arc welder, intro to computers, hybrid am modulator, HR10 rx mods, 10M transistor am tx, 40M gndplane, IC logic demonstrator, overload protection, if/rf sweep generator, digi freq counter, aural tx tuning.

DEC 72. SSTV scope analyzer, 2M fm rx, tone burst encoder and decoder, universal if amp, autopatch hookup, LM380N info, voltage variable cap info, 2M 18 watt amp, SSB modulation monitor, xtal freq/activity meter, 10A var. dc supply, transmission line uses, radio astronomy, inductance meter, 75 to 20M transverter, LED info, 40M preamp, transistor vfo, 1972 index, 2M preamp.

JAN 73. HT-220 touchtone, 3-el 20M yagi, 50 MHz freq counter, speech processor, 2-tone gen, fm test set, tilt-over tower, 6M converter using modules, tuneable af filter, six band linear, 10M IF tuner, diode noise limiter, cw/ssb agc, HW22a transceiver 40M mod, HAL ID-1 mod.

FEB 73. CW id gen, tone operated relay, toroidal quadrature ant, active filter, time freq measurement (part 2), repeater timing control, SSTV circuits (part 1), 2M converter using modules, multifunction metering, FET biasing, freq counter preamp, TR22 hi-power mod, transistor rf power amps (part 1), light bulb rf power indicators, 75A4 filters, capacitance measurement, Gonset 201 mod, world time info.

APR 73. FM deviation meter, 2M FET preamp, two 2M power amps, repeater control (part 1), repeater licensing, European 2M fm, fm scanner adaptor, RCA CMU15 mods, lightning detector, cb alignment gadget, transistor rf power amps (part 2), repeater economics.

JUNE 73. 220 MHz sig gen, uhf power meter, repeater licensing info, RTTY autoswitch, 40M hybrid vfo tx, ant polar mount, 10-15-20M quad, K2OAW counter mods, double coax ant, ham summer job, tone decoder, field strength meter, nicad battery pack, ohm meter, FCC regs (part 1).

AUG 73. Log-periodics (part 1), tone burst gen, rf power amp design, transistor radio intercom, 160M ant, SSTV monitor, low cost freq counter, VOM design, qrp 40M tx, 432 MHz exciter, fm audio processing, FCC regs (part 3).

SEPT 73. Repeater control system, log-periodics (part 2), 2M rx calibrator, PLL ic applications, TT pad hookup, Heath HW7 "s" meter, Oscar-6 doppler, 2M coaxial ant, 2M converter, IC keyer, measure ant Z, FCC regs (part 4).

OCT 73. GE Pocketmate mods, microwave freq measurement, CA3102E 2M frontend, 2 kw hf linear, rf wattmeter, meter repair, 60/40 dipole, IC "hi" gen, vhf freq multiplier, FCC regs (part 5).

NOV 73. 450 MHz exciter, intro to ATV circuits, nicad voltage monitor, autopatch connections, IC meter amplifier, TR22 ac supply indoor vertical, IC af filter, momentary powe failure protection, 160M ant acoupler, Motorola HT info, SSTV-ISB, Class-B af amp, FC(regs (part 6).

DEC 73. Code speed display, 2M kw amp, I(keyer, 8038 waveform gen, helical resonato design, sensitive rf voltmeter, proximity contro switch, IC tester, sequential tone decoder, 2I portable beam, electronic calculator math, c filter design, FCC regs (part 7).

FEB 74. SSTV monitor info, IC audio amp scope sweep gen, 15/20M vertical, telephon line control system, pc board constructio var-Q af filter, blown-fuse indicator, 40m c stn with Ten-Tec modules, simple preamı compressor, single-IC rx, "432-er" final assen bly, transistor keying circuit, 7-segment readou with nixie driver.

APR 74. Vox for repeaters, tone-operat relay, hf transverter, 10-to-2m tx converte remote control panel for scanner, RCA fm tuning, subaudible tone gen, FCC regs (part 5 Repeater Atlas.

MAY 74. Cd car ignition, audio compress info, interference suppression for boats, au burglar alarms, 2m ic preamp, 10m fet co verter.

JULY 74. 4-1000A linear, universal freq g universal afsk gen, 555 IC timer, 80M phas array, 135 kHz-432 MHz preamps, 10M qrp tx, 3000 vdc supply, how to read diagrams.

AUG 74. Toroidal directional wattmeters, 4 MHz FET preamp, use gdo to find " Trimline tt pad hookup, R390 & R392 mods, tracking cw filter, aural voltmeter, versal regulated supply, sstv scan converter, logic problems, ID timer.

SEPT 74. MOSKEY electronic keyer (part ex warning system, Heath 10-103 scope mc qrp 6M am tx, rf speech clipper, audio n limiter, wx satellite on SSTV monitor, unive IC tester, miniature rig construction, to construction, infinite rf attenuator, electr

(Mor

Since there's little to get stale in back issues of 73 (our magazine is not padded . . . like others . . . with reams of activity reports), you'll have a fantastic time reading them. Most of the articles are still exciting to read . . . and old editorials are even more fun for most of the dire predictions by Green have now come to pass. Incentive licensing was every bit the debacle he predicted . . . and more. You'll really get a kick out of the back issues.

photo flash ideas, IC "select o ject."

OCT 74. Microtransistor circuits, synthesized HT 220 (part 1), repeater government, regulated 5 vdc supply, fm selcal, removeable mobile ants, Motorola metering, 2M vertical collinear, Motorola model code, 2M coaxial dipole, 1.6 MHz if strip, MOSKEY electronic keyer (part 2), carbon mike circuit, hi power lo pass filter, 6M preamp, 3 wire dipole, ATV sync gen, NCX 5 mods, mobile whip for apartment dwellers, sstv auto vertical trig.

NOV 74. K2OAW counter update, regulated 5 vdc supply, wind direction indicator, synthesized HT 220 (part 2), 20M 3-el beam, auto patch pad hookups, double-stub ant match, novice class instruction, digi swr meter (part 1), 6M converter (1.6 MHz if), "C-bridge," MOSKEY electronic keyer (part 3), Aug. sstv scan converter errata, repeater off freq indicator.

DEC 74. Care of nicads, wind speed/direction indicator, wx satellite video converter, electronic keyer, hints for novices, unknown meter scales, SSTV tape ideas, TTL logic probe, public service band converter, tuned-diode test receivers, digi swr meter (part 2), telephone pole beam support, rhombic antennas, 1974 Index.

FEB 75. Heath HO 10 scope mod for SSTV, electronic keyer, digital satellite orbital timer, Oscar 7 operation, satellite orbital prediction, Heath SB-102 mods, comparing FM & AM, repeater engineering, Robot 80-A sstv camera mod, neutralizing Heath SB 110A, "Bounceless" IC switch, tape keyer for cw tx.

APR 75. $50 walky for 2M, 2M scanning synthesizer, 88 mH toroid info, 8-function repeater controller, nicad battery precautions, TR22C preamp, telephone attachment regs, Guide to 2M Hand-held Transceivers, 2M 7-el beam, basic telephone systems (part 1), 10 min ID timer, modified hf Hustler mobile ant for 2M, 15M quad modified for 20M, 2M collinear beam, R 11A surplus rx conversion, 5/16-wave 2M ant, Hallicrafters SX-111 rx mods, 160M cw tx.

AUG 75. 146/432 MHz Helical ants (part 2), 10 min ID timer, digi swr computer (part 1), debugging rf feedback, DVM byer's guide, wx satellite monitor, cmos "accu-keyer," pc board method, sweep tube final precautions, compact multiband dipoles, small digital clock, accessory vfo for hf transceiver, modern non-Morse codes, multi function gen, 2M scanning synthesizer errata, KP-202 walky charger, 10M multi element beam.

SEPT 75. Calculating freq counter, wx satellite FAX system (part 1), IC millivoltmeter, three button TT decoder, troubleshooting sstv pix, 40M dx ants, 146/432 MHz helical ants (conclusion), digi swr computer (conclusion), reed relay for cw bk in, NE555 preset timer, power failure alarm, portable qrp rig power unit, precision 10 vdc reference standard, 135 kHz if strip, telephone handsets with fm transceivers, Motorola T 44 tx mod for ATV, 0-60 MHz synthesizer (part 10, ham radio PR)

corder, and digital call counter. It's a beauty!

I built the identifier from the Robert Glaser article in last April's issue ("A Reprogrammable ID"), and it works like a charm. I made some changes in the timer and I am using only two buttons to do the programming.

Another two projects I built from the April issue are the "5 Dollar 100 Watt Amplifier," a nice 2 meter antenna, and the "Mighty TR-22/15" little amplifier, which is now the afterburner of my VHF Engineering rig base station.

Now I am putting together "MINI-MOS — The Best Keyer Yet?" by WA6EGY, on page 38 of the August issue.

There is no doubt that *73* is the leading magazine in the business.

Congratulations, again, and keep the good work and the stream of good stories coming.

Albert H. Coya WB4SNC
Miami FL

BUG VII

An error was spotted in my "Fun Counter" article (July issue). The leads on IC3, pins 5 and 6, should go to pins 6 and 7 respectively in Fig. 6(a).

A. E. Plavcan
Anaheim CA

CURRENT?

First, keep up the logic and computer articles. I'm a computer freak and really enjoy them. The people who complain about computer articles are like the League people who fought transistor articles in *QST*. You can't stop progress. It's only up to you whether you stay current or not.

Dick Murphy WA1SPI
Marlboro MA

GOOD STUFF

As soon as I received the July issue, and read Bob Way WA9VGS's article on the Keycoder I, I said I had to have one. So, I collected the parts and got to work. Since Bob had not specified the precise Amidon part number, I fired off a message to him about it. Got my answer and got it built. And that is one of the things I really like about your magazine — the articles are reasonable things to build without a machine shop or microwave lab, are useful or interesting gadgets, use parts that can be found, and, based upon my huge sample of one, work. The Keycoder is the very first thing I have ever built from a magazine, so maybe you can imagine my joy in getting it to work properly and well.

Now that you have my money to extend my subscription for three years, please keep the good stuff coming.

Ralph Jay Frisbie WB6GNS
Camarillo CA

ENDBUG

Just a note to call your attention to a mistake in the parts list of the "12 Inexpensive Volts" article on page 60 of the September, 1976, *73*. In regard to T1, the list calls for a 2731510 12 V 3 A transformer. This particular Radio Shack number, however, is for a 6.3 V 3 A transformer. The correct part number is 273-1511.

Yonkers NY

GEORGE

On June 9, youthful thieves entered the locked car of George Keys WA6KAA, which was parked overnight in the driveway of his home. They snatched a two meter rig that George had purchased only two weeks earlier.

George took action.

The Santa Maria *Times* of June 12 carried an ad offering to exchange a Johnson CB rig for the stolen 2 meter rig — with no questions asked. That evening a telephone call cinched the trade. The next morning George had his HA 146 returned and the two young men left with the Johnson CB rig.

George had their description.

It was circulated to members of the Satellite club. One member related the description to an incriminating conversation someone he knew had overheard. It was sufficient for Sheriff's deputies to make the two arrests, breaking up a CB theft ring and recovering a number of stolen CB rigs in the process.

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

73 SUFFERING?

Is *73* really dropping circulation, as ARRL recently reported in *HR Reports*? The fact is that *73*'s growth this year has been without precedent . . . and both *HR* and *QST* know it. They are hearing this from readers, authors, dealers (who tell them that *73* is outselling their magazines in the radio stores), from newsstand wholesalers (who say the same thing) and, worst of all, from the advertisers.

The growth has been a pain . . . but a most bearable one. We've just had to double the capacity of our computer system . . . and it was supposed to hold us for a couple more years. We've had to do second printings of the April, September and possibly October issues because incoming subscriptions have been so far beyond our projections . . . and that is horribly expensive. The staff has gone from 30 last year to 45 this year to handle subscriptions, mailing lists, promotions, artwork, writing, editing, printing . . . etc.

Despite the rash of I/O articles in *73* this year, the subscriptions have been growing faster than ever before in our history (hey, did you see the microcomputer article in *QST* for August!). The *73* formula of lots of articles, few contest results, few activity reports, few PhD type of technical articles and tell it like it really is approach, which is more in vogue after Watergate, seems to work. Few but older hams seem to be buying the blind loyalty bit these days . . . most want to see signs of responsiveness and relevancy.

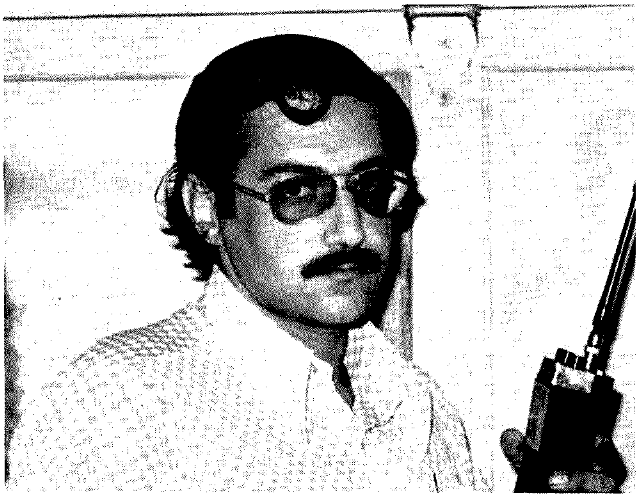
Let's add up the pages of ads in the ham magazines for the last half of 1975 and the first half of 1976 for a direct comparison. Keep in mind that ads in *QST* cost about 10% more than those in *73*.

73	971 pages
QST	735 pages
HR	624 pages
CQ	306 pages

Perhaps the chart above will put things into perspective. It shows *73* with 32% more ads than *QST* (and a lot fatter magazine . . . without all the contest results, SCM reports, and that stuff). After over 50 years as number one, this is a very bitter pill to swallow, and it is no wonder that there is some nervousness in Newington. Figures lie and liars figure, to coin a phrase.

TECHS'LL PROBABLY HATE ME

Not a few people have petitioned the FCC to open part or all of ten meters for Techs. It is a matter of religious significance to some Techs.



Since hamfests, conventions and computerfests are commercial affairs, 2m HTs should not *be used for coordination. Here's one of the officials of PC-76 in the middle of a no-no. This sort of thing would be okay using CB, but not ham radio.*

At the present time I am neither for nor against the idea. However, I would like to see someone come up with a good reasonable argument which would convince me that it was a valid idea.

Yes, I think I know all of the arguments . . . but I may have missed some. Ten needs activity . . . no question about it. But blessed if anyone has come up with any data which indicates even remotely that Techs will use ten meters if we open it for them. All that data I've seen so far points the other way.

Six was the biggy a few years back . . . right? You could find about 90% of the active Techs chewing away on six . . . maybe 95%. Then some chap (prizes if you know who) started really pushing two meter FM and repeaters and got things perking up there. Instant flushing of six . . . which turned into a ghost band. Now 95% of the active Techs were on two meters, with a thin scattering on six, 450 . . . and even a half dozen or so on 220 MHz.

From that, one might be tempted to suspect that Techs (like all other classes of hams) tend to go where the action is. OK . . . so what about ten meters? Well, with over 200,000 licensed amateurs with tickets which do permit them to operate on ten . . . and with a mere handful doing same, why on earth should we expect Techs to suddenly reverse their practice of ignoring inactive bands? When you have a good explanation for that, let me know and you'll find a heavy hand pushing for Techs on ten.

If Techs are so great at helping keep bands busy, where are they on 220 MHz? Where are they on six meters? You know where they are . . . they are on two meters. And I don't want to hear from the tiny band of pioneering Techs who are out there trying to shovel coal up the chute (to coin a phrase), fighting a tough battle to keep *something* going on bands other than two. Fair is fair, fellows.

WARC — WHAT YOU CAN DO

Okay, so most of us are worried about what might happen at the next ITU conference in 1979. Again there is every reason to worry, particularly if you have any real knowledge of where amateur radio stands with other countries.

As I mentioned in my October editorial, the only chance that I see

Continued on page 176

BE MY GUEST

visiting views from around the globe

Little...

Every day records are falling. Divers are setting new underwater poker playing records. Jets are crossing the Atlantic at supersonic speed. A group of Nashua, New Hampshire folks recently set the world's record for rocking chair rocking. And out in a small midwestern town this summer, a five year old boy has earned a Novice class amateur radio license. It boggles the mind.

Neil "Rusty" Rapp WN9VPG of Vincennes, Indiana will only start first grade this fall. At age four the boy's reading ability was estimated to be at the fifth grade level. His Novice code test features inch high letters, and a better score (103) than his father. Rusty learned the code in only seven weeks and passed his theory exam in about half an hour. Already he's bored with the Novice bands, and is studying hard for his General.

As near as we can tell, the old world's record for youngest ham was Gary Lewis WN7BBJ. Lewis was seven when he got his license, but the *Callbook* says he's no longer licensed, or has another call. A fellow in Washington now holds N7BBJ.

Rusty began on the CB bands, after his dad, now a Novice, bought a CB radio. Rusty caught on fast, memorizing handles and callsigns and becoming a local legend on channel 13. He used the handle "Little Shadow."

At Christmas time, the elder Rapp dusted off a code key and oscillator and decided to get into ham radio. Father and son had been practicing for several weeks when they spotted an ad in the local paper: The Old Post Office Amateur Radio Society was offering Novice classes, the minimum age requirement being 10.

The first night, Del Rapp left his son home, afraid of the age limit. But there was a ten year old girl enrolled, so the next week it was Rusty's chance. Three weeks later, father passed the code test, but Rusty failed. He'd been told not to turn over his paper . . . but since the boy wrote in such big letters, he'd run out of paper and couldn't copy enough characters.

Rusty, according to his mother,

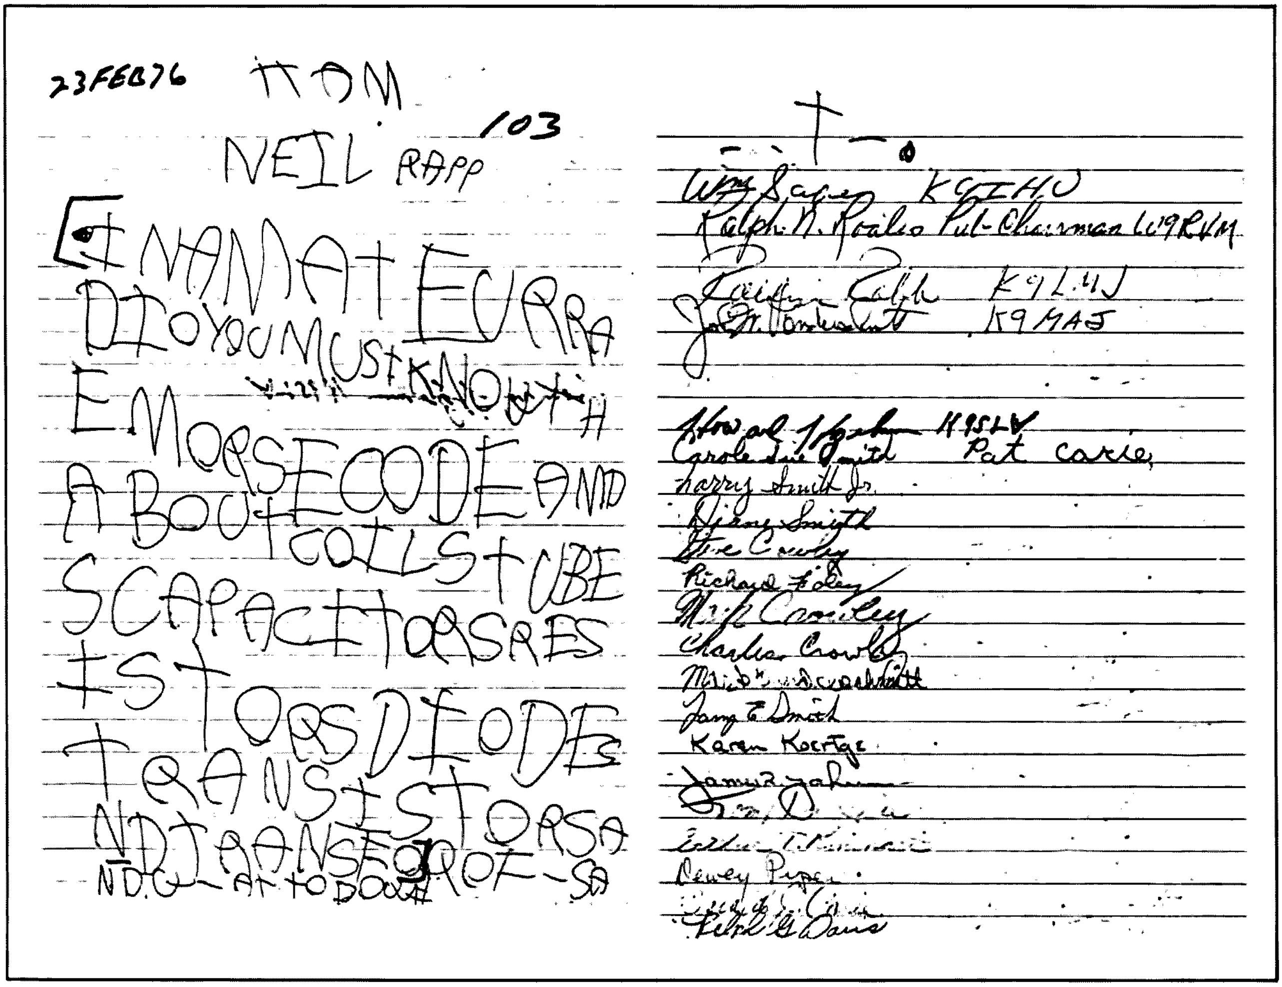


Photo by Paul Willis

cried until midnight . . . and there were doubts whether he ought to continue. Two weeks later, the code hurdle was eliminated, thanks to the watchful eyes and ears of Bill Sage K9IHU, the club code instructor.

Then it was onto theory and it was tough going. Rusty's mom decided to come up with a game, so the boy could memorize the questions and answers "backwards and forwards." They put the questions on one set of cards and the answers on another. Father and son then questioned each other with gusto, using pennies and then peanuts to reward correct answers.

The Rapps must have gone through a lot of peanuts, because it turned out the FCC lost Rusty's application. More than three months after the code test, it was finally time for theory.

It must have been quite a sight, a five year old boy poring over the exam questions . . . filling out the computer answer form. How many of us have been there, with years of schooling and hours of study, only to fail and have to try another day. Theory instructor Howard Hazelman K9SLV probably still doesn't believe it. When Rusty passed his code test, the entire class signed his exam paper . . . because the instructor feared no one would believe a five year old boy could pass.

You can imagine the look on K3DIF's face when he gave WN9VPG his first QSO on 15 meters. It turned out K3DIF worked for Associated Press in Washington, DC, and the story of the world's youngest ham was on its way into print. A half dozen radio and newspaper stories followed. Rusty even heard from First Mama Betty Ford, who replied with a big 10-4 and a form letter signed, "Nice modulating with you!" (The White House is apparently short of ham radio form letters.)

One thing's sure: Rusty Rapp's achievement should be an inspiration to all of us, whether we be Novices seeking General class licenses, CBers trying to get into hamming, or Advanced licensees struggling to get the code speed up to 20 for the Extra. There is something to that ancient saying, "And a little child shall lead them . . ." Meanwhile, I'm firing up on 21.120 MHz this Sunday for the Old Post Novice Net, at midnight GMT, hoping to reach that five year old Novice and taste a bit of the world's youngest fist.

. . . News

A recent report to the Office of Telecommunications Policy, Executive Office of the President, warns of the potential for breakdown of the federal regulatory system in the face of rapidly developing telecommunications technology. Prepared by Arthur D. Little, Inc., the report foresees the headlong growth of Citizens Band radio resulting in new criminal techniques and the Postal Service threatened with obsolescence. Even AT&T's gaining a monopoly of all broadband distribution to the home is among other possible impacts of technological change.

Martin Ernst, director of the study, says the report is not a prediction, but a warning of the kinds of chaos that could result if the status quo is maintained. "It's not a matter of more regulations," he stated, "but of how telecommunications should be regulated. Much of the technological change we assessed is already well on its way. It can't easily be turned back. The regulatory framework has to be rethought to deal with the possible social impacts," he explained. "Overregulation certainly is not the answer. In fact, sections of our study focus on the dangers of too much regulation, especially if it cannot in practice be enforced."

Commissioned by the Office of Telecommunications Policy as the first step in the process of planning for the impacts of telecommunications change, the report consists of five scenarios. They develop possible, though not necessarily likely, chains of events in such fields as mail delivery, CB usage, broadcast distribution, broadband communications, and education. The scenarios were developed to dramatize a broad range of possible impacts on individuals, society as a whole, and the economy.

Pervasiveness of Telecommunications

The visible forms of telecommunications (telephones, television, radio) give few clues to its pervasiveness. The invisible nature of its more critical aspects (electronic networks, communications satellites, cable systems, and other operations which make these things possible) has led to its casual acceptance, according to the report. "Most users are unaware, for example, of the technical, economic, and political considerations that determined specifications for equipment such as television sets before they could be marketed or what alternative performance possibilities were and are available. Not only the costs and quality of equipment, but even personal safety and national security can be determined by remote decisions that are difficult for all but the most experienced and well informed to comprehend fully," the report states. Similarly, few of the recipients of electronically transmitted Social Security payments, Citizens Band radio enthusiasts, or cable TV customers are aware of the mechanisms involved and the potential for sweeping change represented therein.

With the possible exception of transportation, the report points out that telecommunications has no rival in the degree to which it is a part of American life. Repercussions of seemingly isolated and relatively unimportant decisions regarding a single aspect of it can affect a broad range of human activities. For example, a CB radio frequency band decision to open more channels would affect imports and thus, among other effects, change the balance of payments. It also could affect treaties with other nations, notably Canada.

The meteoric growth of Citizens Band radio already has overcrowded

the channels available to it. This could affect international relations because the use of present frequencies during periods of high sunspot activity, such as that anticipated in 1979, could interfere with radio operations in other countries where amateur radio is more rigidly controlled. In that context, the study notes, no other nation has permitted access to a Citizens Band because of the many and difficult problems such access creates.

Outcome of CB Radio Boom

The study team developed a scenario of possible events arising from the proliferating use of CB radios. The team believes that hoards of new users and additional uses could in the not too distant future turn the present situation into sheer chaos unless a workable policy is developed. Present policy is the responsibility of the FCC, which has neither the resources nor mandate for enforcement. One typical issue is freedom of speech as affected by FCC controls. CB is already used in organized demonstrations; this raises the question of the legality of police use of jamming to maintain law and order in riot situations. Privacy and the use of scramblers versus monitoring for illicit use is another example. At least eight federal government agencies (FCC, OTP, Commerce, State, Justice, Coast Guard, Defense, Interior) and local governments will have to contend with the potential impact of CB.

USPS Headed for Obsolescence?

Already beleaguered, the United States Postal Service (USPS) is perceived by the report as one of the more vulnerable organizations in the path of the telecommunications onslaught. Despite the vital function it has performed for society for two centuries, the USPS has limited freedom with which to combat the encroachments which have begun. Electronic funds transfer techniques already in use can significantly substitute for the 35 percent of all mail (two thirds of first class) accounted for by financial transactions (orders, invoices, bills and payments). Because Postal Service operating costs reflect the number of deliveries which need to be made, not the volume carried, the loss will disproportionately affect USPS revenues.

A second threat lies in the growth of digital data and facsimile networks which might ultimately be used for a large portion of intra- and inter-business messages. With advancements like these making mail service obsolete for many business purposes, massive subsidization might be required to maintain national mail service for individuals. This could result in very much steeper postal rates (approaching 35¢ an ounce for first class mail in the mid 1980s), the need to pick up mail from central drops, or else pay for deliveries.

The USPS can respond with its own electronic transmission to move mail from one location to another. However, the most profitable portion is what is handled by telecommunications companies which can avoid the expensive physical delivery process. Unless the USPS is prepared and permitted to compete directly with private industry, it must build its business out of the least economically desirable markets.

Television Struggle

A third scenario deals with the possible outcome of an attenuated struggle between "free" broadcast television and cable and pay television. The potential for competitive advantage afforded by the use of satellites might ultimately lead to the elimination of local TV broadcast stations. Alternatively, current research into the use of optic fibers could lead to telephone companies becoming the most logical providers of home television access in the long term. Regulatory policy will continue to be a key factor in alternative developments and any subsequent change in the television industry's infrastructure. The FCC and other regulatory agencies now face increasing conflict as technology offers new opportunities that favor first one telecommunications industry sector and then another.

Another scenario explores the possibility of two-way broadband communications being extended to cover individual households, permitting access from homes to libraries, data bases, education, entertainment, computers, and other facilities. A fifth scenario investigates the interface between public services and private enterprise in the provision of telecommunications services for health, education, and government communication needs.

Arthur D. Little, Inc.
Cambridge MA

The Persuader

A Boston psychiatrist says CB radio's effect on personality may be too new a phenomenon to draw any accurate conclusions. Dr. Mark Walter of the McLean Hospital in Belmont says it's a matter of people feeling the power and anonymity of the microphone.

Walter told the *Boston Globe*, "It's really a new variation of an old thing . . . we do know that ham radio operators are often the sort of people who enjoy being in a room alone with the power of talking out to the world. They want to reach out and be in touch with people but keep an emotional distance from the same people."

FCC regional director Gerard Sarno goes a step further. Sarno characterizes the average CBer as a "nitwit" who becomes "obsessed with the feeling that they have no other purpose in life other than to transmit on a CB radio. It gives them a source of identity they never had before. And suddenly, if they're criticized by someone else, watch out for them."

Both men were commenting on a recent shooting incident in Boston. Newspaper accounts reported that two friends were chatting over CB when a third person broke in with some flack. "You come over here and say that face to face," one of the friends shot back, adding that he lived at an address in the Back Bay section.

A short time later, in the wee hours, a car showed up outside the Back Bay address. A man jumped out, yelling; "Here I am. Now what are you going to do about it?"

A 44 year old businessman ran out into the street to answer the challenger. Brandishing a .38 caliber revolver, he smashed one of the car windows . . . and pumped a slug into the CB set under the dash, demolishing it. "There, that'll teach you," he shouted back, as he ran into his house.

Carnival Time

The combined effort of amateur radio operators in two states, the Red Cross, and others, has resulted in the return of a missing boy to his worried mother.

Mrs. Judy Lever, Mt. Holly, Vt., had high praise for the amateur radio operators, who located her son, Mark, 13, when others had not been able to find him.

Amateur radio operators in Vermont, including Fern Adams W1YYU, North Clarendon, William Dimick WA1OHB, Rutland, and Mildred Doe K1BQB, Bellows Falls, notified New Hampshire operators that the boy was missing and possibly traveling with an amusement company in New Hampshire or Maine.

"I have a friend who is a ham operator," Mrs. Lever said. "Her set was not working, but she contacted friends, who immediately contacted others, among them Mr. Prescott (J. Longdon Prescott, amateur radio operator and disaster chairman for the Kearsarge Chapter, American Red Cross, in Franklin). We told them we were looking for a carnival, and within two hours they had located the company and my son. I am very grateful to them for the fine job they did."

Amateur activities were coordinated by Edwin Antz of Danbury, net manager of the Granite State Amateur Radio Network, and the WR1ABU repeater, located in Concord.

The particular company Mark was traveling with was difficult to trace, as they moved often. The help of Mrs. Linda Hebert, Carver Street, West Franklin, and amusement publications, determined that the boy was with an amusement company in Calais, Maine.

The Red Cross and company officials made arrangements to transport Mark back to Mt. Holly, but a misunderstanding about time resulted in Mark taking a bus home on Monday.

Mrs. Lever was happy to have her boy back home, and Mrs. Hebert has been commended by the Red Cross for her efforts in locating the missing boy.

Report from Boston

The Federation of Eastern Massachusetts Amateur Radio Associations has been putting on conventions for years now. There have been those bigger than this year's version, held at the downtown Boston Statler Hilton. Most of the biggies had come to the now departed New Ocean House in Swampscott, but that was before the CB explosion.

Not that the CB influence hurt attendance much. A lot of CBers turned out, just to see why all those folks were breaking channel 19 to find the hotel. Convention officials said they had a record day Sunday . . . but the exhibitors were another story. Less than fifty showed up, and five of those were computer oriented. Several manufacturers said they were using the same displays at CB conventions, by simply inserting new signs (to change that loaded whip exhibit from 27 to 144 MHz). The economics of the CB boom then became one of the unspoken exhibitors.

A highlight of the weekend was WR1ACO's long distance link with WR6ABM in the San Francisco Bay Area. The Malden association has done it before, with a July 4th spectacular that linked Boston with Hawaii and Philadelphia. But this time, instead of the club paying the bill, the cost (about $150) will be borne by a small group of Boston FMers. A high point (or low point, depending on how you look at it) was one poor fellow's query, aired on both coasts, whether it was just conditions or what? He even signed his calll Plans to broadcast remarks by ARRL President Harry Dannals W2TUK during the convention banquet had to be scrapped, because of problems on the West Coast side. But once the system was debugged, all went well. WR6ABM, incidentally, is microprocessor controlled.

Back at the convention . . . Heath was introducing its new synthesized 2m FM rig, the HW-2036. An earlier attempt, you'll remember, was recalled because of spur problems, although company engineers say the earlier model would have worked, if most hams had access to spectrum analyzers. Heath says the new version puts spurs (within 20 MHz of carrier frequency) down 70 dB. It's due before Christmas.

A close competitor will be the Icom IC-22S, a 22 channel synthesized 2m FM rig which features a diode matrix system for user setup of desired channels. The Icom was the talk of the convention, with dealers taking scores of orders and much speculation about the new model's impact on the 2m market. It looks like the 22S will become a modifier's delight, with several schemes already afoot to externally program the synthesizer through outside switching. Company officials say demand is so great that it could be months before the orders are filled. But they continue to deny that the IC-230 is about to follow the IC-22A into oblivion. Rumors nevertheless persist that Tempo's VHF 1 digital readout rig will soon have an Icom competitor.

On the HF side . . . Kenwood-Trio kept a constant crowd with their new TS-820, despite the fact not one dealer at the convention had any to sell. Kenwood officials noted increasing pressure for them to sell direct, a violation of longstanding company policy, and could only urge people to keep plugging at their local dealers. CushCraft introduced a new four element tri-band beam, model ATB-34. With an 18' boom and 30'8" maximum element length, it's bound to stir up the tri-band market. One real plus is CushCraft's plan to include a 1-1 balun as part of the deal. The first ones ought to be coming off the assembly line soon.

Hy-Gain has apparently applied some of its CB R&D money to the ham bands, with a new line of VHF-UHF mobile antennas. They use an etched copper loading coil on a PC board and even offer one that covers 6 and 2m. The idea first appeared with Hy-Gain CB antennas.

One of the biggest disappointments had to be the convention flea market. For two days some die-hards hung in there, but the downtown location took its toll, since the pickings were so poor. To say the least, Boston was no bargain for flea marketeers.

All that aside, it was a pretty good convention. All the elements (except the fleas) were there . . . and the Boston crew came through with their usual outstanding prize program (everything from a weather station kit to a TR-4C). One big change was the mounting influence of microprocessor hamming. The seminar schedule was loaded with it, and, with 3 retailers and an equal number of manufacturers in evidence, it's apparent that ham radio is in for another revolution. Typically it's in for another round of controversy as well, as the debate over microprocessors gets underway in earnest.

Bennington NH

Hams to the Rescue

Using the airwaves and lots of goodwill, a band of local ham radio operators cut through international red tape to airlift a seriously ill American from Mexicali to a hospital here.

Robert Lake Carden Jr., 27, of New York state, was in Veterans Hospital today after the San Diego County Amateur Radio Council put up $1,700 bail for alleged crimes in Mexico and flew him here in a rented plane piloted by a local ham.

Members of the club got the original bail reduced from $9,000 to $1,700; a member put up all the money at once pending pledges that were made over the radio.

Another member rented a four-seater plane and flew down to Mexicali yesterday, the bail was paid and the Mexican Red Cross rushed Carden to the border at Calexico.

The Fire Department there supplied another ambulance which sped to the airport, where Carden was placed in the plane and flown to Montgomery Field. He said very little on the flight.

An ambulance service waived its customary fee and took the heavily sedated man to the hospital.

Doctors there were conducting a series of tests to determine the exact nature of Carden's illness. He had told some of the hams that he was dying of throat cancer and could not get proper treatment in Mexicali.

Carden's flight to freedom began a few weeks ago as he lay in the general hospital at Mexicali. He told Umberto Wang, a medical student, that he was dying of throat cancer and wanted American ham operators to contact his mother in New York.

Wang happens to be a ham, and passed the message along to a fellow Mexicali ham who he knew was in contact with hams on this side of the border.

Jim Smith of Ocotillo, who belongs to the San Diego ham outfit, picked up the call and relayed it to many of the 4,000 members of the group. One of them called Carden's parents, who said they had no money to help.

Interest in the issue spread quickly, and a "Rescue Robert" fund was established with the goal of bringing the man out of Mexico. San Diego hams appealed for help to the U.S. consulate in Tijuana, but were unable to obtain assistance.

Paul Hower, a local ham who piloted the plane yesterday, explained how Carden came to be in custody according to what the man told Smith. The Ocotillo man visited Carden often during his many trips to discuss the matter with Mexican officials.

Carden told Smith he lives in Lockport, N.Y., and served three years in the Marine Corps. He was on the West Coast in April visiting friends.

In Barstow, he met a man and two girls who invited him to go to Mexico with them, he said, and the group visited border cities.

One of the girls paid for the food and lodging of the group with credit cards she said belonged to her mother, Carden said. However, a Mexicali hotelman got suspicious and called police.

The other couple had fled, but Carden and one girl were arrested. The girl was freed because she was 16; Carden was jailed.

But he was hospitalized when he became ill with what he said was cancer of the throat. He said that he had been fed intravenously for 60 days and would die if not treated in this country.

Johnny Johnston, a ham who got involved in the case, went to Mexicali

Looking *West*

Bill Pasternak WA6ITF
14725 Titus St. #4
Panorama City CA 91402

We have probably heard the nation of Israel referred to as the "Garden" of the Middle East, in that from this "desert" the Israel people have carved a flourishing land of plenty – a place that they call a "land of milk and honey." It seems as though it's not only the products of "old Mother Nature" that have come to flourish there, but VHF and VHF repeaters as well. How do I come to make this statement? Thanks to Yuval 4X4FN, recently portable 6, Looking West has the opportunity of bringing you a bit of information as to what Israeli amateurs are doing with two meters.

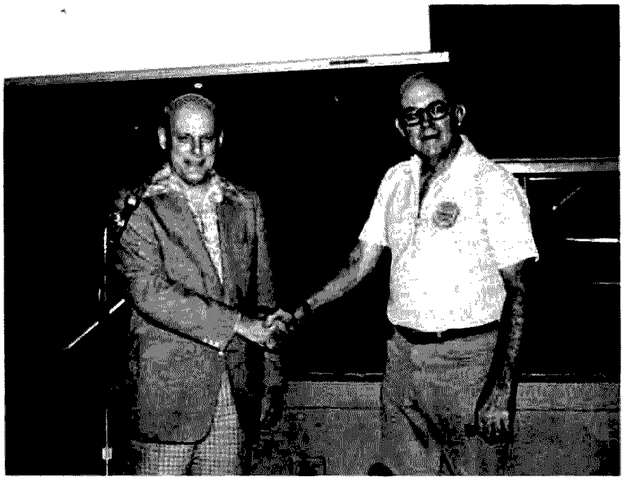
Yuval was on a trip to the southland when I encountered him on the WR6ABB repeater system here in Los Angeles. To be a bit more specific, he was en route from Los Angeles to San Diego and had a lot of time to pass as he headed south on I-405. After introductions and the "warm PARC welcome," I began to question Yuval about what is happening VHF-wise in his homeland, with the following being a summary of the information that came forth as a result.

At present there are at least three operative two meter systems, all operating on the same channel pair of 145.175 in and 145.775 out. One of the three operational systems is located in the area of the city of Haifa, another near Beersheba, and the last at Kibbutz Sasa (serving the Upper Galilee). A fourth system, also on the same channel pair, was being prepared for the Tel Aviv area when Yuval departed for the USA. Whether it is operational or not at this writing is unknown.

Now, unlike repeaters here in the USA, Israeli repeaters do not have distinctive callsigns such as the WRs we have come to know, and most simply operate under the call of the amateur or amateurs responsible for the installation of the system. Most do not have auto-ID, so you sort of have to kerchunk a system to see if it's on the air. According to Yuval, "visitors" using these systems are quite welcome, and American amateurs planning to visit Israel can obtain a permit to operate by contacting the appropriate ministry prior to departure to secure a permit. I believe that it was the Ministry of Communication, but I am not too sure since by this point signals were beginning to drop out. Possibly it was the Ministry of Transportation; I will try to clarify this point in the near future.

So much for repeater operation, but for this story. Simplex (direct) is also alive and well and growing rapidly. The prime simplex channel is the repeater output frequency of 145.775, but when that channel is busy you will find the overflow sitting on both 145.25 and 145.50, in that order. In the Tel Aviv area, I am told that simplex is busy most of the day and well into the evening. Language barrier? Not according to Yuval, since he says that most Israeli amateurs speak fluent English. And with this you have a quick glance at what VHF-minded amateurs elsewhere in the world are up to – a chance to glimpse at the achievements of others in the worldwide community we know as amateur radio. Now on to what we promised last month, or at least close to it: a glimpse at a real great guy on a trip here to the southland, John B. Johnston K3BNS, Chief of the FCC's Amateur and Citizens Division.

In case you have not guessed it by the foregoing, I happen to like John. In my personal opinion he is the best thing to happen to amateur radio in the many years that I have been a part of it. What he has accomplished on our behalf in just one short year is something that he and we can all be proud of. Thanks to his trust and belief in us, and his willingness to press for more freedom from regulation so that amateur radio can again grow and prosper, he will long be remembered within our ranks.



San Fernando Valley ARC President Fred Killitz WB6EJG formally welcomes John.

I had hoped to arrange a private interview with John while he was here in L.A., and had even approached Capt. Dick McKay K6VGP, John's host, on the matter. Unfortunately, due to schedule conflicts on my part, no feasible time could be found. The simple fact was that I had to put in a lot of overtime at work, and that limited my free time a bit. However, I found myself in a position to attend and participate in two evening open meetings that John had with area amateurs. Before continuing, though, and in deference to John, I must say that the format I will follow is that of transcribing from tape both the questions and John's answers, close to verbatim. These questions were posed by members and visitors to meetings sponsored by the Palisades Amateur Radio Club in Culver City and the San Fernando Valley Radio Club in Panorama City/Van Nuys, during the week of August 16.

First, let us set the scene. The place is the Veterans Memorial Hall in Culver City, California, the evening of August 18th. Dan Deckert WA6FQC, President of the Palisades Amateur Radio Club, addresses the assembled multitude. Dan proudly welcomes John to this meeting on behalf of PARC, and introduces him to the audience. This introduction is followed by a 3 minute standing ovation – a totally spontaneous showing of affection toward their friend from back East.

John began the formal part of his presentation, after greeting the crowd, by showing a series of color slides that told about himself: his specific interests in amateur radio, his station, the radio clubs he has and does belong to, and some of his friends within the amateur community. It was a "here I am, come get to know me as a fellow ham" presentation that gave us all a bit more insight into this "man from the FCC." Then came the part that most of us had awaited – the open format question and answer session. All questions were made from the floor by fellow amateurs just like you and me. The following are what I feel are the pertinent subjects covered in both the meetings I attended and taped.

Question: What about 1979? (Questioner was referring to where amateur radio will stand at this upcoming conference.)

John: We probably have about the best organized working group of all the groups and I say that because Merle Glunt, who is the ARRL man working on that, who used to work for the FCC and is possibly one of our top international negotiators, says that he attends all the meetings: broadcast, common carrier, and so forth. He says we probably have the best organized group, and I also know that when we did our report – we have to file with the Library of Congress – as for the amateur, we have the best looking report, too.

However, that's to establish the FCC position, and I think, shortly, before too many months, there will be a first of a series of Notices of Inquiry coming out with what the FCC position is. I don't think we're going to get everything in that notice that the amateurs asked for, because we asked for an awful lot. We asked for all of our present bands; for our present bands to be expanded; for some new bands; and, you know, really sort of gorged ourselves writing to Santa Claus. But the fellows working on the group have done a fantastic job. Apparently they're working on a new document – that's the amateur group – to further support and justify our need for those frequencies.

Some of them (frequencies) are in trouble. I guess you've heard about the one that's probably nearest and dearest to your hearts, 146 to 148 MHz, which is not an amateur band in some parts of the world. I believe that the maritime or aviation is after that, looking for more VHF frequencies. 75 meters, 3.9 to 4.0 – the broadcasters have their eyes on that. The broadcasters also have their eyes on 160 meters, so, who knows? It's going to be an uphill fight all the way.

Question: This docket 20777, the bandwidth/mode docket. What is the purpose behind it?

John: We are trying to deregulate the service as much as possible. All regulatory agencies are under great pressure to deregulate and, looking around the FCC, the only service that was really asking for deregulation was the amateur service.

One of the big problems amateur radio has always had with the Commission has been when a new mode came along – a new teletype mode or whatever it is. Slow scan came along; that was a problem for a while. The Commission felt that in order to authorize someone to use that mode, they (the Commission) would have to have the equipment to monitor and intercept those messages to make sure they were consistent with the rules.

I tried to make a giant leap forward; I said that, well, maybe that thinking was good for the 20s or 30s or something like that, but it's harder and harder to get the appropriations to buy that equipment, particularly when you say you want to use it to monitor amateur transmissions – it's really tough to get the budget for that. So, let's try and go with something simpler. Maybe not talk about emissions – talk about bandwidth, though it's recognized that amateurs don't have a great capability in measuring bandwidth. But maybe if they had the requirement, things would develop. Maybe not. But then it would open up a whole new future, especially for the experimenters who wanted to experiment with new types (of emissions), and maybe amateur

radio could bring new modes of communication to the other services, develop new modes of communication.

The comments we've gotten seem to be kind of divided between the people who are forward looking and can appreciate that, and those who would say, "What about AM? . . . I like talking to my buddies on AM on 75 and I bought my rig 25 years ago and I hope I never have to buy another one."

Of course, the League, you know, did reject the whole idea, so I don't know. We really haven't scoured through those comments yet. But we were a little disappointed; we hoped we would get more from the amateur community on ways to solve this bandwidth measurement problem. It looked like by and large they've sort of thrown up their hands and said, "It's beyond us," which wasn't probably too good of a result – and frankly I think that we're probably back to "square one" looking for new ideas.

Question: What kind of reaction has the FCC received on the new RACES docket, and do you anticipate any alterations?

John: (Begins commentary with funny anecdote deleted here due to space limitations.) Basically, the amateurs came to us with tales of these very serious abuses that the local governments, the police and fire departments, who are eligible for their own services, were making of RACES. The Commission was just about ready to do away with it completely; that is the Department of Defense thing. We kind of presented the argument of "Let's give it one more chance. Let's take it out of the hands of the local governments. If they've got problems with frequencies and emissions available to them in their services, work those out within the services. Don't try to twist something in amateur radio around the wrong way, and let's try and get it back into the hands of the hams."

I don't have very many checks on that other than that the number of applications coming in has been very small, I understand, and we really don't know whether it is going to be a viable program or whether we should just go ahead and do away with the whole thing. I can't really tell at this point; I think it's too early.

Question: Two questions on the bandwidth docket that a lot of amateurs might be interested in. First of all, what about the future of ASCII, the computer code, and secondly, what about the future of amateur TV on 450? The bandwidth docket would essentially eliminate fast scan amateur TV from 420 to 450 MHz. What is the Commission going to do on both of these?

John: Well, you see, ASCII was one of the driving forces behind this, because in order to authorize it we have to go convince Congress to give us the money to go and buy ASCII machines to put in all of our monitoring stations around the country. You could put this away once and for all; then you come up with a better code and we are still talking bandwidth.

The television on 450: As you know, there has been quite a battle on the East coast with the television repeaters, and it did seem to be a rather localized thing. In order to bring out some discussion on this, and see what in the world do amateurs want to do with this, let's propose that they move on "up the band," where you can point and say they really are doing some development work. For TV on 450, it's awfully hard to make a case that "that's development work" and so forth. On 1215, 1296, it's a different story. I think that amateurs could make some very, very worthwhile contributions there, but there has been a reluctance to go because it's easier to get 450 gear, as you know. And we did note that out here, in this part of the country, that you were using 450 for voice communications very heavily. So we did want to get that question out in the open and give all sides a chance to comment and to raise the issue.

Question: Johnny, I don't know whether you are aware of what has been going on in the field of amateur radio public relations, especially out here, but what do you think of amateurs going to the public and introducing amateur radio to them like on radio, TV, etc?

John: Fantastic! Absolutely fantastic. You know, it used to bother me when I was in the rules branch; I used to keep track, and by golly, every time I checked we were losing an average of 350 licensees a month. 350 a month! It just kept going down and down and down, while all the other services were going up. Now there have been a number of things which have happened.

Of course, a lot of people have now become introduced to the glories of two-way radio by virtue of "that other service." But amateur radio has begun to spring up, and a lot of it has to do with the public relations work you are doing and the work your clubs are doing in the training programs. That really is great.

I have heard Commissioners in the past say that "hams were an elite group" – a closed group – and they really weren't living up to all those purposes in 97.1 and all that. It really warms the cockles of my heart to see this (referring to the new attitude of today's more outgoing amateurs in "going public").

There's more . . . a lot more . . . two cassettes full, but for this month we are plum out of space. We will continue with John's comments next month, along with a few other goodies. In the meantime, I wish to express my sincere gratitude to Jim Davis WBØSQP/6, who "blew into town" at the right time and with the proper recording equipment to make a lot of what you read this month possible; to Bill Orenstein KH6IAF/6, whose exceptional expertise in the field of audio and public address systems made recording the San Fernando Club a snap; and most of all to Mr. John B. Johnston K3BNS, for visiting with us in our town and at our radio clubs and for being the warm and gracious individual he is. If ever you have a chance to attend one of John's presentations or should you get a chance to have him as a guest speaker at your club, jump at the opportunity. You will be glad you did.

It was SRO at the San Fernando Valley ARC for John's program!

John is greeted by Lenore Jensen W6NAZ, ARRL public relations assistant for Southern California and "amateur radio's most charming lady."

CONTESTS

Editor:
Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

Please send all contest information directly to me at the address listed above, preferably at least three months before the date of the scheduled event. In other words, the announcement for an event on May 1, 1977, should hopefully be submitted by February 1, 1977.

TAC CONTEST
Starts: 1800 GMT
December 4
Ends: 1800 GMT
December 5

Entries may be single or multi-operator class. All contacts on 3.5 to 3.6 MHz, CW only. General call is "CQ QMF."

EXCHANGE:
RST/001 and progressive QSO numbers from 001.

SCORING:
Contacts with own country, 1 point; each call area in W/K, UA etc., VE/VO, and VK counts as separate country. Contacts with stations in same continent, 2 points; other continents, 5 points. Contacts with HQ station GW8WJ or GW6AQ count 25 points. Total score is sum of contact points times total number of prefixes worked (same as for WPX).

ENTRIES:
Logs must be sent not later than January 31, 1977 to: Peter Lumb G3IRM, 14 Linton Gardens, Bury Saint Edmunds, Suffolk IP33 2DZ, ENGLAND.

ARRL 160 METER CONTEST
Starts: 2200 GMT Friday
December 4
Ends: 1600 GMT Sunday
December 5

The 7th annual ARRL 160 Meter Contest is open to all amateurs on CW only. Multi-operator work is permitted and scores will be listed separately in the results, but they will not be eligible for certificates.

EXCHANGE:
RST and ARRL section or country.

SCORING:
QSOs with amateurs in an ARRL section count 2 points; QSOs with amateurs not in an ARRL section are worth 5 points. DX to DX QSOs do not count. Multiplier is the total number of ARRL sections (74), VE8, and foreign countries worked.

AWARDS:
Certificates will be awarded for section and non W/VE country high scores. Division high scores will have their section award endorsed with an appropriate seal.

FORMS:
It is suggested that contest forms be obtained from ARRL, 225 Main St., Newington CT 06111. Check sheets are not required but a penalty of 3 additional contacts will be made for each duplicate contact.

These rules were taken from last year's contest. For complete rules, see the November issue of QST.

ARRL 10 METER CONTEST
Starts: 1200 GMT Saturday,
December 11
Ends: 2359 GMT Sunday,
December 12

The contest is open to all amateurs worldwide. All QSOs must take place on 10 meters and OSCAR QSOs are valid. Each station can be worked on phone-to-phone and CW-to-CW, and anyone can work anyone. All CW contacts must be made between 28.0 and 28.5 MHz, unless working through OSCAR. When operating on 10 meters, please avoid the OSCAR downlink frequencies.

CLASSES:
Entries will be classified as either single or multiple operator stations. Multiple transmitter stations are not allowed.

EXCHANGE:
All W/VE stations will send RS(T) and state or province. Others will send RS(T) and consecutive serial number starting with 001. Stations that are not land based will send RS(T) and ITU Region (1, 2 or 3). The District of Columbia is counted as part of Maryland.

SCORING:
Each completed QSO counts 2 points, or 4 points if with a W or K Novice. The multiplier is the sum of the total number of states, Canadian call areas (max. 9), ARRL countries (not US or Canada), and ITU regions from non-land based stations. Final score is the sum of the QSO points times the total multiplier.

AWARDS:
A certificate will be awarded to the highest scoring single operator station in each section, Canadian call area, and foreign country. Region awards for non-land based stations, and awards for multi-operator and Novice stations will be issued if warranted.

FORMS:
It is suggested that contest forms be obtained before the contest from ARRL, 225 Main St., Newington CT 06111; include an SASE. Check sheets are not required but a penalty of 3 additional contacts will be made for each duplicate contact.

These rules were taken from last years contest. For complete rules, see the November issue of QST.

HUNGARIAN DX CONTEST
Starts: 1600 GMT Saturday,
December 11
Ends: 1600 GMT Sunday,
December 12

The contest is sponsored by the Hungarian Radioamateur Society and is open to any licensed radio amateur. All amateur bands from 80 to 10 meters may be used on CW only. General call is "TEST HA" while Hungarian will give "TEST WW." Entries may be in any of the following classes: single op, single band; single op, multi-band; or multi-op, multi-band.

EXCHANGE:
RST and continuous serial number from 001. After their signal report, Hungarian stations will give a two letter code for their location (county) as follows: BA, BP, BE, BN, BO, CS, FE, GY, HA, HE, KO, NO, PE, SA, SO, SZ, TO, VA, VE, ZA.

SCORING:
Each HA QSO counts 1 point. The same station may be worked only once per band. Each different HA county worked counts 1 multiplier point per band. Final score is total QSO points times sum of multiplier points from each band.

ENTRIES:
Logs must be made in usual form with summary sheet and signed declaration. They should be mailed within 6 weeks after the contest to: Radio Amateur League of Budapest, H-1553 Budapest, P.O. Box 2, HUNGARY.

AWARDS:
Certificates to first place station from each country in each class or section. Additional places if warranted.

ARRL STRAIGHT KEY NIGHT
0100-0700 GMT SATURDAY
JANUARY 1

Check *QST* for any changes in the rules!

Basically, rules require the use of a straight key only. Send "SKN" instead of "RST" during QSOs, to help identify contest stations. On 80-40-20 meters, try 060 to 080 kHz up from the bottom edge of the band. On Novice bands, try 10 kHz up from the bottom of the Novice band. After the contest period, send a list of calls of the stations contacted during the contest period, plus your note for the best fist heard. Please mail entries as soon as possible to ARRL, 225 Main Street, Newington CT 06111.

SOWP CHRISTMAS QSO PARTY

The Society of Wireless Pioneers will conduct a membership on-the-air QSO Party on the weekend of December 18 and 19, 1976. The party will cover the full 48-hour GMT period and will be the first "voice" party scheduled by the Society. The purpose of the affair will be to give members an opportunity to meet one another and to pass along their season's greetings, etc. There will be

CALENDAR

Dec 4 - 5	ARRL 160 Meter Contest
Dec 4 - 5	TAC Contest
Dec 11 - 12	ARRL 10 Meter Contest
Dec 11 - 12	Hungarian DX Contest
Jan 1	Straight Key Night (ARRL)
Jan 15 - 16	QRP Winter Contest
Feb 19 - 20	YLRL YL-OM Contest – Phone
Mar 5 - 6	YLRL YL-OM Contest – CW
Mar 26 - 27	CQ Worldwide WPX SSB Contest
Apr 12 - 13	YLRL DX-YL to Stateside YL Contest – CW
Apr 26 - 27	YLRL DX-YL to Stateside YL Contest – Phone

Note: The official dates for the 1977 ARRL contests had not been announced at the time of this writing. Tentative dates should be:

Jan 1 - 2	VHF Sweepstakes
Feb 5 - 6	DX Contest – Phone
Feb 5 - 13	Novice Roundup
Feb 19 - 20	DX Contest – CW
Mar 5 - 6	DX Contest – Phone
Mar 19 - 20	DX Contest – CW

no formal exchange requirements and no need to submit logs.

All members with a phone capability are encouraged to participate. The call will be CQ SOWP. While there will be no certificates awarded, everyone who takes part will be a winner by having an opportunity to renew old friendships, establish new ones and to continue a comaraderie developed over the years.

Suggested frequencies for the affair are 25 kHz (±) 5 kHz up from the low end of the General class phone portion of each amateur band.

BUDAPEST AWARD

This award was originally founded in 1963, but the rules were changed effective January 1st, 1976 as follows:

The certificate is issued in one class and may be received only once. There are no endorsements. Contacts are valid after January 1, 1959, but each station may be used only once in your application. Any amateur band and mode may be used including active land or air VHF/UHF repeaters. European stations must contact 75 HA5 or HG5 stations, while DX stations (including US) need only contact 25. On VHF, only 50 different HA/HG5 stations or 5000 kms summarized distance; any contacts made via satellites or via the moon count with 500 kms/QSO value. Send a list of your contacts and 10 IRCs to the Award Manager of BRAL, Dezso Tarcsay HA5HA, H-1553 Budapest, P.O. Box 2, HUNGARY. The award is also available for SWLs on a "heard" basis with the same rules and fee.

BICENTENNIAL WORKED ALL STATES NET AWARD

The Bicentennial Worked All States Net that meets on 3905 kHz nightly at 0500 GMT is now offering its award for working all states during the Bicentennial year. All contacts must be made on the net frequency during net operation or at least within one hour of the beginning or closing of the net. They must be made from the same QTH (or from locations not more than 25 miles apart) and confirmed in writing. Cost of the award is S2.00 and QSLs need not be sent; only an application form verified by another amateur is requested. For an application and complete information contact Gene Densmore AA4WCG, 2125 Cambridge Drive, Tallahassee FL 32304. By the way, the awards will not be numbered or dated other than 1976, so there is no rush or time limit other than making the required contacts during 1976!

WORKED ALL NEW HAMPSHIRE

The Concord Brasspounders, Inc., of Concord, N.H., are again making available to all qualified amateurs their Certificate of Achievement for working and confirming all ten New Hampshire counties. The ten QSL cards or a request for information should be sent to Basil Cutting W1JB, Suncook, N.H. 03275.

Effective 1 October, 1976, all AO-7 mode B orbits which fall on GMT Mondays will be designated as QRP orbits, as was done during mid-June, 1976. The success of the three day QRP test has prompted these extra QRP orbits, and it is hoped that users of the AMSAT-OSCAR 7 mode B transponder will reduce their signals to the recommended *ten watts* effective radiated power during these orbits. The use of lower power is also highly recommended during other AMSAT-OSCAR satellite passes because of the beneficial effect it has on the battery. As AO-7 grows older, its battery is deteriorating, and this deterioration is accelerated by users running higher power than is being recommended by AMSAT (100 Watts effective radiated power). This 100 Watts erp *maximum* is enough power to produce very readable signals from horizon to horizon with a small antenna and the average 144 MHz receiving setup. If mode B users cannot hear their 100 Watt erp signal at all times during a pass of AO-7, they should look at their receiving system and should NOT raise their power in order to hear themselves. With cooperation from all users, the AMSAT-OSCAR 7 communications satellite will provide service for the worldwide radio amateur community for years to come.

LETTERS

FORM A POSSE

WA1LET is on the prowl after the rip-offers. After my friend WA1SGX had his 2 meter rig ripped off his car, I put my thinking cap on and started the wheels turning, and this is what I came up with.

I am a member of the "Fidelity Amateur Radio Club," so I am going to propose a rip-off committee, with each member equipped with an Avalanche transistor oscillator in his rig (commercial manufacturers take note) tuned to an outboard receiver (such as a tunnel diode job) so that in the event of his set being ripped off, he can locate the direction his set is going. After the set has gone beyond the legal limit of the license free transmissions set by the FCC, that is where the club gets in the act, by having a club sponsored sensitive receiver able to tune to all the club members' frequencies, giving a master control to direct the posse of members going after the rip-off artist and, with such aid, should be able surround the culprit, giving the guy 3 choices: turn him over to the police, hang him, give back the radio with loot to cover the damage done to the owner.

Remember the old days. It will be like a rustler hunt. Maybe I have been reading too many westerns. I believe that only by action on the part of the hams will we be safe from the easy-picking boys. Every club should form a protective committee. The Avalanche oscillator is the only oscillator (I believe) that can give a tremendous pulse with small power. All the bright boys should get busy and send in to *73* their brain child, or send to me, WA1LET, so that we can all get together and scotch the pilferers. I have not had any trouble myself, but have stuck my neck out in the cause of the hams, e.g., in the dockets that have been an enemy to the hams, even when it did not affect me. I hope that my little gabfest will do a little good.

Cy Lievesley WA1LET
142 Brightman St.
Fall River MA 02720

The wheels turned alright — and made mush.

FAIR WEATHER FRIEND

Congratulations on two major counts: 1) for bringing *73* to what it is and continuing to improve it, and 2) for that editorial in the October '76 issue that I just read. I've read some of your "editorialism" in the past that has (on two occasions) caused me to drop my subscription to *73*.

This one shows class. This one tells it like it is — all the way through — about the uPs and even about the contents of *73 Magazine*. I'm referring (if you hadn't guessed) to the I/O Editorial.

I like *73* because *now*, more than any other time in its history, it is a broader-based electronic experimenter's journal. Keep going, and please keep us informed regarding your upcoming Pers-Comp mag.

I've been hamming for about 10 years, from 80m through 450 MHz, and am just recently gaining a keen interest in computer electronics — especially uPs.

Bob Gromer WA7NMJ
Glendale AZ

Thanks, oh fair weather friend. — Wayne.

FUTURE SHOCK

As I was reading the August issue of *73* (around the fourth of July), the article about the computerized ham station seemed very familiar.

Digging through my vast collection of *73* mags, I found a story in the January, 1967, issue. The story was called, "The QRZ Machine," and at the time was science fiction.

The "machine" was described as being about the size of a portable typewriter, and was able to copy CW.

The 1976 Altair microprocessor is a bit larger and in the example copied RTTY, but that ain't bad in just 9 years.

Where would we be today without science fiction to encourage scientific experimentation and advancement?

Tom Grabowski K3SPY
Baltimore MD

Better off.

ABOVE AND BEYOND

Just a few informal remarks and comments on two of the firms that advertise in *73 Magazine*.

I placed an order with B & F Enterprises in Peabody, Mass., for two speaker enclosures as advertised in *73*. Although they did not advertise crossover networks, I asked them, if possible, to send me two threeway crossovers. The order arrived minus one crossover. A communication followed shortly after saying they were backordering one crossover, as they only had one for the original shipment. I asked them to charge the amount of the purchase to my BankAmericard. Now they could have charged me for the whole order, but they only charged me for what they had shipped, involving additional paperwork when they shipped the second crossover, which arrived a few days later. Now this showed consideration and fairness with their buying customers. Also, the shipment arrived so promptly that I don't see how they could have checked out my BankAmericard account before shipment. It is a pleasure to do business with companies that show consideration in their dealings with the buying public.

I also placed an order with Aldelco of Lynbrook, N.Y., for some diodes and other materials. I sent them a postal money order to cover the amount of the purchase, and when the order arrived, there had been an error filling the order as they did not send me some of the diodes that I had ordered, and they sent some that I had not ordered. I sent them a communication stating what I had received and not received and asked them to check my original order. I offered to send the diodes that I had not ordered back to them on arrival of the diodes that I had ordered, to fill my original order. A few days later, the diodes that were missing in the original order arrived with a note of apology and stating that I did not need to return the unordered diodes, but to keep them with their compliments. Now you can't ask for anything more fair than that.

And so, Wayne, thanks for your care in selecting advertising firms that are reliable and considerate to advertise in *73*. It is a pleasure to us readers of *73* to do business with that type of firm.

Continued success to you and your staff.

J. Wm. Anderson W6QV
Sunland CA

THE REVOLUTION

Your computer articles have brought me up-to-date after being out of the data processing business for over four years. During this time, I am amazed at the microcomputer revolution, in terms of the available processing power for such a small cost. As a former programmer and computer salesman, perhaps you would benefit from some of my reflections on the current state of the art — sort of like the comments emanating from your "Ancient Aviator."

My first reaction to the microcomputer revolution is simply that very few people even begin to appreciate the problem-solving horsepower possible with a microcomputer. Back in the 1960s I sold small scale business computer systems (for a $100,000 plus purchase price) that were roughly comparable in processing power with the new 6800s and 8080s which are available for less than $10,000 for a disk system. In view of this, it appears that the public must be "educated" in terms of how a microcomputer can be used as a tremendous extension of the mind to handle both home and business applications. To put it another way, less emphasis should be placed on silly games and more thought should be directed towards the way to put a microcomputer to work in the household, hobby and business world.

My second reaction: With the availability of low cost computing, there is a need for good self-teaching programmed instruction manuals and teaching aids. It seems that, at this point, we have low cost effective hardware with a scarcity of materials capable of quickly acquainting the uninitiated in their use. If this market is to grow, this problem must be solved with self-teaching applications and programming manuals, as well as manuals that will show how this equipment can be used in solving the day-to-day problems for which it is so well suited.

My final reaction applies to the question of how to best communicate current knowledge available to other amateur radio operators like myself. In this respect, it seems that we need to organize a hobby computer net that will meet regularly to disseminate useful information. If you know of such a net, please let me know. Also, I would appreciate having the names and addresses of any hobby computer user groups which would be willing to share their knowledge with us mid-westerners who are just beginning to learn about this west coast developed technology.

Robert E. Bunn WAØLKE
Bunn Oil and Supply Co.
508 Porter Wagoner Blvd.
West Plains MO 65775

If you get netted let us know. Re self-teaching, that's what reading 73 *I/O articles and* Kilobyte *is all about.*

THE ELECTRONIC MENSA?

I've just read the article by Robert Fields in the September *73*, and fault it only insofar as it fell short in its castigation of the God Syndrome rampant in amateur ranks.

First, I'm not a CBer (not recently — when CB was young, and legality was in vogue, I had a license, but it has long since gone west). Nor am I a ham. My familiarity with both code and theory is adequate to allow my getting a General ticket tomorrow if so desired, but as of this writing I have seen no facet of ham radio sufficiently challenging that I should waste time so doing.

Further, inasmuch as the majority

of hams of my acquaintance are pompous, stuffed-shirt elitists with delusions of grandeur, I find no incentive in joining up just for the company. And, it is this insufferable arrogance that is turning off would-be hams in droves.

Also, let's forget that bull about ham radio being anything more than a medium for rag chewing. The experimental phase went out with the 6L6, and modern R/D labs backed by corporate financing are the innovators now, not the basement black-box builder. The day of the lone inventor is just about kaput. Granted, hams are using state-of-the-art technology — computers, TV, etc. — but none of it came from ham circles.

If you ham types want to multiply your folds, get off your goddamn pedestals, dismount from your shining white steeds, and mingle with the masses. Anyone with half a wit who's had a taste of modern-day CB would welcome ham radio if, in it, he could find the camaraderie that CB, with all its failings, offers on and off the air. It is sad that in most cases he encounters the snobbery of ham radio's electronic Mensa, and, as Mr. Fields says, trots off to unload his wallet on a Pentax instead of an ICOM or a Heathkit.

K. T. Derek
Pittsfield MA

Well, OM, there is some truth to what you say . . . that part about CBers being friendly. Other than that it appears to me that you are a sad victim of what is called projection in psychological circles. If you do decide to give hamming a try, I think you may find, as the rest of us have, that hams are about as friendly a gang as you could ask for . . . they help each other . . . love to talk . . . and are going way out of their way all over the country to help CBers get their ham tickets. Sure there are a few curmudgeons . . . they are there in CB too, but that doesn't change the average ham from being a great guy. If you'd read much of 73 you would know that hams are in the forefront of many new technical developments . . . such as RTTY, SSTV, and even computer applications. As one of the founders of American Mensa (1960) and a member ever since, I have attended meetings in many cities and seldom have I run up against the snobbery you seem to have found. If that were the case, Mensa would have disappeared long ago. I wonder what other readers think about hams being snobs? — Wayne.

SATISFIED

I am prompted to write this both in praise and disgust.

The praise goes to the Delaware Emergency Net for their damn good work during the Belle hurricane: Elmer W3YAH, Vince W3SEG and all the others who pitched in and did their very best.

Elmer lives on Lewes Island, and when the island was being evacuated, he said "As long as I have power, I'll be on the air, and when I lose it, I'll go too." That is ham radio above and beyond.

The disgust is with the selfish slobs who sat down right on freq and, after repeated reminding, called CQ and finished a QSO, and also with the ones who opened up with an unmodulated carrier for extended periods.

Well, I said it, and I'm satisfied. Thanks for listening.

Bill Simms WA2JNV
Toms River NJ

Jamming is a growing facet of amateur radio.

FEEDBACK

Please note a correction to my article, "ASCII/Baudot Converter for Your TVT," which began on page 150 of the November, 1976, issue. In Table 2(b), $5/A_1$ should be a one instead of a zero.

Jeff Roloff
Champaign IL

Let's watch that stuff, Roloff.

COMMON INTERESTS

Keep up the good work on *73*; it is appreciated. I am not a microcomputer nut (yet), but the articles are interesting as I use an IBM system 360/370 in my work. The ads for Mother Bell are an eye-opener, especially for those of us who work for AT&T. It's nice to see the two communications interests (Bell and ham) cooperating for a change. Now if the FCC will just let us legalize tariffs for phone/autopatch systems!

Arv Evans K7HKL
Salt Lake City UT

GOTTEN

A short comment on your I/O Report in the August issue of *73 Mag*: I think you are really missing the boat by excluding the DEC LSI-11 and PDP-11/PDP-8 programs from your section. Various computer clubs around the nation have acquired OEM status with DEC to buy LSI-11s in quantities and pass the low prices on to members. One club in California has helped over 500 hackers to get LSI-11s. When I was working at DEC, the orders were flooding in. And why not, for the price of an Altair or IMSAI look what you can get from DEC . . . the LSI-11 is about $650, an interface is another $100 or $150, and all you need is a power supply and terminal. No need for a monitor program with the built-in ODT debugging. And it comes with 4K x 16 RAM standard, with power fail and line clock! They also produce a PDP-8/A, a single board PDP-8 that would also be in the price range of the hobbyist. On top of all this, DEC has been making MPS boards for several years that also may be of interest to hackers.

Bob Baker WB2GFE
Atco NJ

I think you got me on that one, Bob. I wasn't thinking of the LSI-11 when I singled out the DEC PDP-11. There is certainly going to be hobbyist (and other) software generated for the LSI-11 which might be of interest to I/O readers. If any comes my way I'll give it every consideration. And with regard to the PDP-8 . . . I hope we see software for it coming into the hobby community both from simulators being written (for an 8080) and/or from the popularity of the Intersil 6100 getting a boost. — John.

AN I/O RECORD

In response to one of your ads, I recently purchased the Godbout Software Board. First, I would like to commend Godbout for their excellent service and their fine product. I received my order within five days after the order was placed — a record for computer-related items.

I experienced a few problems in interpreting the literature. I left my number with Godbout and later that day Bill Godbout returned my call — from California to Chattanooga — and we soon had the problems resolved. The Software Board worked the first time I plugged it in the Imsai computer.

To operate this board, one just "examines" location F000 in hex or 360,000 in octal and then hits Run. Thereafter one enters programs using the Intel 8080 mnemonics.

73 Magazine seems to have a policy of accepting ads from only reputable dealers who won't rip off the ham. For those hams considering entering "computronics," you would do well to stay with such firms as Godbout, Hal Communications and those who advertise in *73*. You haven't seen any Trigger Electronics ads lately, have you?

Nenad S. Downing WB4SLO
Chattanooga TN

Trigger . . . hmmm, wasn't he a QST advertiser?

GONE FISHING

I have used my back issue ham literature to "bait" CB operators. To date can count one total convert and several "nibbles." Photo taken at my portable QTH.

Hal Empie WA7ZYD
Duncan AZ

INACTIVE BROTHERS

This is a CQ to all hams who are

heart pacemaker wearers! Numerous letters to the ham journals indicate a growing need for information about EMI (electromagnetic interference), especially as it relates to ham operating! Pacemaker wearers generally do not have access to reports of EMI susceptibility tests made by military and/or federally sponsored (FDA/BRH) testing programs. As a result, the lack of relevant information leads to confusing, and often erroneous, "advice" from well-meaning but ill-advised individuals.

As a pacemaker wearer since April 1975, and a ham since 1924, I have been compiling interference data in an effort to (1) know my own operating limitations, if any, and (2) to help any other hams with pacemakers who are staying off the air because of fear of pacemaker failure caused by radiation from their rigs.

Will any reader who wears a pacemaker write me and describe any experience which seemed to have been EMI related? For convenience, and to elicit the maximum information, I have prepared a questionnaire which is available for an SASE. This is a worthwhile project, but many answers are needed. For a little bit of your time and a postage stamp, you could get an otherwise inactive brother ham back on the air! QRU?

W. R. (Bill) Schoppe
481 89 Ave. N.
St. Petersburg FL 33702

POINT

In answer to Dave Powell WA4BRI's question in the Letters column of October "Why build in an error?" with reference to my "Instant Counter Calibration" article in the August issue of *73*: There is no error from a practical standpoint!

I won't argue the position that 15,734.265 Hz is the theoretical color horizontal sync rate. In practice, however, 15,734.26374 Hz won't be found any more often than 15,734.265 Hz for the simple reason that the idea behind using a rubidium standard in broadcasting is not so much absolute accuracy, as it is long-term stability. The broadcaster isn't as interested in the absolute frequency (as long as it is well within FCC tolerances) as he is in phasing his local and/or remote equipment to one *stable* standard. This circumstance, however, doesn't make using the horizontal sync signal any less valuable for the radio amateur because it is the most accurate signal available to the average ham, plus it is traceable to NBS through the published offsets.

Additionally, as was mentioned in my article, unless your counter is phase locked to the incoming signal, there will be a ±1 digit ambiguity. My Heath IB-1103 would interpolate Mr. Powell's figure of 15,734.26374 Hz as 15,734.264 Hz, and the least significant digit ambiguity could make this either 15,734.263 Hz or 15,734.265 Hz. To compound the dilemma, the guaranteed one second stability of the Heath counter is .5 ppm which in my case does indeed make the .08 ppm *error* WA4BRI refers to seem insignificant.

My caution with regard to making sure that you are tuned to a network colorcast is aimed mostly at some locally originated CATV (cable) system programs and newly formed low-budget broadcast stations who may not be referenced to a rubidium source. I would still stand behind that statement. The caution regarding "mini-cam" units also stands, if they are in the field and feeding back *live* video via microwave as the statement in my article implies. In this case, they are almost certainly not rubidium locked!

Incidentally, and in closing, I couldn't help but notice the piece in *QST*'s "Hints and Kinks" column for August, 1976 (which arrives *much* later than *73*'s August issue) recommending the same procedure that I cautioned AGAINST using, i.e., connecting directly to the TV receiver circuitry with the counter. I sincerely hope that no one falls victim to serious damage by using the *QST* approach (quite a "kink").

David F. Miller K9POX
Niles IL

Picky, picky.

COUNTER POINT

The letter by Dave Powell WA4BRI in the October letters regarding the article "Instant Counter Calibration" by David F. Miller K9PQX has introduced more errors than it has corrected!

The television networks employ far more precision in frequency generation than required by the FCC rules. The signal source as noted by Miller is a rubidium atomic oscillator for NBC and CBS and a cesium atomic oscillator for ABC. These sources synthesize 5 MHz. The color subcarrier is developed by multiplying 5 MHz by 63/88, producing the figure quoted by Miller, 3.5795454.

Next, take this number, multiply it by 2 and divide by 455. Presto, you have Miller's 15.734266.

In the future, it might be helpful to submit critical letters to the original author for comment before publication.

The references listed below contain more information on using color TV signals for calibration.

Michael S. Robbins K6QAH
Los Angeles CA

You're quite a bookworm, Mike.

INFLATION, ETC.

I would appreciate it if you would publish the following in *73* as soon as possible:

"REPEATERMEISTER"
UPDATE

All negatives requested after 15 August, 1976, will incorporate the changes described below.

CW ID

ID initiate input IC, 7432, now has four initiate inputs — pins 1, 2, 4 and 5. Use 330 Ohm resistors to ground. This makes operation more convenient and less wasteful of gates.

Clock oscillator IC, 7400. Use a 5k trimpot with a 1k ¼ W resistor in parallel. This improves the operation of the oscillator and also limits the sending speed from 5 wpm to about 25 wpm.

TX hold transistor, Q1, 2N708. Any general purpose NPN switching transistor may be substituted. Be certain that IC will not be exceeded by the keying circuitry in the transmitter. Also, foil pattern has been modified for the following change: At the collector of Q1, install two germanium diodes with the band towards the collector of Q1 (1N34 or 1N60). Jumper one diode to pins 4 and 6 of IC2a. This gives a 5 second tail after each ID. Jumper the other diode to the collector of Q4 on the MLB, which is the PTT output.

MLB

Pads have been added to the 7413 Schmitt Trigger for the input-output connections.

Replace the jumper at IC2 from pin 4 to the collector of Q2 with a germanium diode, band towards Q2. A pad has been added at pin 6 for the jumper from the CW ID described above.

Receiver off timer, IC3, 555. On some negatives pins 6 and 7 are not connected. Solder bridge these pins for correct operation.

Same goes for the transistors on the MLB. Any NPN general purpose switching transistor may be used. Be certain that Q4 can sink the required current from the keying circuitry that follows.

The 100 Ohm resistor on the collector of Q3 may be increased to 150 Ohms.

The resistor value in the schematic, 2.2 megohms, at pins 6 and 7 of IC3, 555, is the correct value, although 1.5 meg is shown in the parts layout.

Pads have been added for the 1.8k resistor at the base of Q5, the autopatch control transistor.

Due to increased costs of materials (mainly film), after November 1st negatives will be $.75 each. Preprogrammed 8223 IC available. Your chip and $4.00 plus message desired; or $7.00 and message desired, I supply IC. Etched and drilled boards on G-10 glass epoxy also available. $7.00 each or both for $12.00 (limited supply). Approximately two weeks delivery.

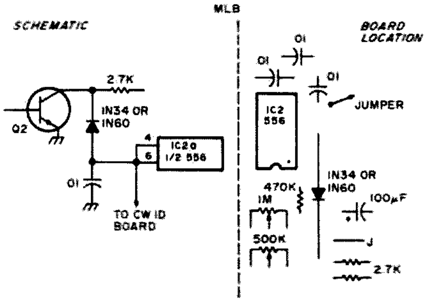
OBSESSED

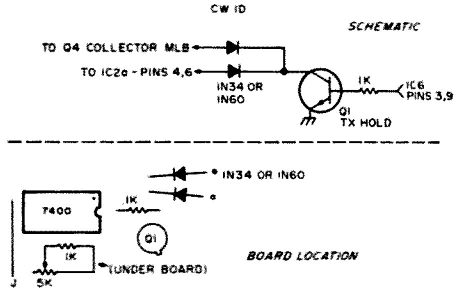
I read those gripes in your mail about small computers in your mag. I hope you don't give in. A couple of years ago when I saw articles about them in the popular mags, I brushed over them thinking they were just toys — like imitations of the *real thing* (which of course no one but a genius could understand).

This is my tenth month of intensive concentration on them. I became involved because I wanted to translate commodity market prices coming in on a telegraph line into price display and possibly charts so I could trade them without losing so much money.

I'm building a home brew affair with Altair compatibility.

Knowing I would need a display, the "Sol" terminal seemed like just





the thing (Processor Technology). Maybe I could use it to translate the special hex code into ASCII as well, so I ordered a circuit board and spent a week locating and sending for all the other stuff only to find out they are redesigning it and I won't get the board 'til September. It's a good thing I haven't started on the CPU board, because *now* I'm going to *have* to get a Zilogue board instead.

In other words, the information explosion has gotten me. Not only do I have a busted bladder, but bleary eyes from reading all that fine print in spec manuals trying to learn enough so the thing will be sure to work when I get it finished. (Could it ever be?)

You guessed it. I'm obsessed with computers, day and night. Even though my puttering goes back to the oatmeal box tuning coil and the 01A tube, nothing has bitten me quite as badly as the computer bug. So keep up the good work — no construction articles with lines running off the page to something or other. If we don't actually see it hooked to something, how can we be *sure* where it goes?

Out here, we appreciate what you're doing, so keep up the good work.

"Brad" Bradford
East Braintree MA

I get into enough trouble without your encouragement. — Wayne.

OFF BASE

We've been licensed for over 56 years. Were on a little before that, before licensing was required by Herb Hoover, who first took charge. Came on first on 300 meters with spark, then 200 meters, then 1750-2000, then 1800 to 2000 and the rest of the bands.

When *73* first came into business, we were one of your first subscribers, and also wrote you a few articles. Boy, how the years do fly!

Quit *QST* years ago — no longer a *real* ham organ as it was when "Hiram" ran it (and later his immediate successors). Present boys are more for business interests than hams. Hams play 2nd fiddle! Buy *QST* now and then to see if it's any better, but no! HI!

Wrote an article a couple of years ago pointing up how a few manufacturers such as Millen will sell direct to hams to promote building (I'm a builder — always was). In it I criticized those manufacturers who make components and also equipment for making components hard for hams to get — so as to force purchase of equipment. I compliment Millen and others who either sell direct to hams or *promote* components to distributors (instead of blocking distributors), etc., etc.

QST refused to print it. It would have helped hams who build, but *QST* was more concerned about their "big boy" advertisers!

Just thought you might like the above facts for what they are worth.

Jim Grindle W9QS
Chesterton IN

Jim, I wouldn't have published your letter either, and not for fear of any advertisers . . . but because I think you are off base. Distributors got out of the parts business because it was not profitable . . . pure and simple. One result of the incentive licensing (proposed by ARRL/QST in 1963) was that not only did ham growth stop and over 75% of the sale of equipment stop for several years, but hams stopped building, too. It got so Lafayette was the only place you could buy parts as several hundred distributors gave up the ghost. Parts houses are back in force now, but are more specialized . . . Godbout, James, SD Sales, Optoelectronics, Bullet, Verada, Poly Paks, Meshna, Tri-Tek, Whitehouse . . . etc. — Wayne.

THE NOVICE CLASS

I subscribe to both *73* and *QST*, but find your magazine to be the best. Certainly I tend to agree with your political outlook as regards amateur radio more often than I do that of the ARRL.

I am a new amateur, but with a long time interest in the hobby. I tried once before about twelve or fourteen years ago to get a license but was unsuccessful. Now I am the proud holder of a new Novice ticket. This leads me to write the following comment about the Novice class.

One of the reasons that I didn't get the license earlier was that I wished to skip the restrictions placed upon the Novice (and CW) and go directly to the General class, but I was a fairly young and inexperienced child at the time and found everything involved just too frustrating and just let the whole thing drop. If I had gone for the Novice ticket, I could have been on the air and gathering experience, instead of being just more and more turned off by the whole thing.

In the Novice class that I attended I found the same thing to be still true. There was one small boy (how come there aren't more small girls? — but that's another problem) who was having a lot of difficulty. He could have been coached and hand-held through a Novice exam, but I am not so sure that he could have been coached enough to pass a more advanced test. I know that there are very young children who manage to pass Extra exams, but I am concerned with the average child. For these children the Novice license is ideal, and I think that it should be retained. I am glad to see that the FCC is making steps in the direction of a renewable license in this class.

I took the Novice test because I wanted to be able to operate while I was studying for the General (Advanced really, but I am trying not to give into *hubris*). I would have taken the Technician, but six months ago there were no high frequency privileges for this class. For older, more advanced individuals, this seems to me to be a better entry class.

There are many problems with getting started in amateur radio, and if we want the hobby to grow we should systematically consider them along with possible solutions. I just wanted to air my thoughts on this one aspect of the problem. I am a professional educator and the learning aspects of amateur radio are thus close to my heart.

Pasadena CA

OFF TRACK

Shortly after assembling my SB-401 two years ago, the transmit-receive relay began to stick, especially after lengthy transmissions or extended tune-up periods. Measuring voltage across RL2 revealed that voltage was indeed dropping, yet the relay just wouldn't quit. Popping the function switch to spot would restore normal operation, and running the companion SB-200 seemed to reduce the problem almost completely.

It wasn't until recently that the sticky relay problem finally prompted some real action. A local Novice bought the SB-401 and, after operating CW for a while, aggravated the situation so that the relay wouldn't respond to the old spot trick. Replace the relay was one answer, since it seemed like the problem could be residual magnetism.

A call to Heath showed how far off the track we were. Dave Poplewski knew immediately what we were up against . . . and answered that there were two ways to solve the problem (an expensive one and a cheap one). Needless to say, we were most interested in the cheap way out. Dave explained that the problem was soft finals — finals that were not soft enough to affect output, but soft enough to allow screen grid leakage through RL1 back to RL2. The best cure, Dave advised, was to ground lug 7 of RL1. That way screen grid leakage can't reach the transmit-receive relay, RL2. The expensive cure? Replace the finals.

Warren Elly WA1GUD/1
Bennington NH

One other cure — learn how to tune your rig.

I/O RIP-OFF

Please publish the following letter in an attempt to recover a stolen computer system from my home on or about the fourth of September of this year.

The equipment taken is listed as follows: (1) 1 Altair 8800 consisting of (a) 1 CPU card, (b) 6 88-4MCD dynamic memory cards, (c) 1 16K static memory card (Mikra-D), (d) 1 88-DCDD disc controller card set (2 cards), (e) 2 88-disc floppy disc drives, (f) 1 88-PMC PROM memory card with PROM, (g) 1 88-ACR cassette interface, (h) 1 88-2SIO serial interface with both ports; (2) 1 HP-65 programmable calculator; (3) camera equipment consisting of (a) 1 Honeywell Pentax Spotmatic II with 1.4 lens, (b) 1 Vivatar 85-205 mm autozoom lens, (c) 1 Honeywell 450 autostrobonar flash.

If anyone reading this letter has a reason to believe he has been offered any of this equipment or thinks he has seen this equipment, please contact your local police authorities or contact me at the following address.

You waited too long to write your house security program.

CATCHING ON

Your magazine and the articles in it have shown me the close relationship hams have with each other and this is what encouraged me more than anything else to work for my amateur ticket. Some of your articles are still a little deep for my shallow mind, but I'm catching on. Keep up the good work — you have a fine magazine.

Bill Raney WN5TGS
Laredo TX

THE GENERAL GOOD

This hint has saved me a lot of bother, and you might find it worth passing on for the general good:

You have finally decided that the antenna halliards must be replaced before they fall apart, and you have a length of fine new rope for the job. But how to get it through that pulley at the top of the tower? The sheave won't pass a knot, or even a splice. So you climb the tower, or lower it to the ground. Neither one!

Take a four inch length of coax, RG 58/U for small rope, or RG 8/U for thicker stuff. Cut off and discard all but the braid. Insert one end of the old rope into one end of the braid, and an end of the new one into the other. Pull taut, and the harder you pull, the firmer the grip of the braid on the rope ends. It may be necessary to wrap a few turns of thread around the leading end of the braid to control fraying. Pull down the free end of the old rope and let the new one follow it through the sheave and back to

New Products

EICO DLP-6

If you've been working with digital logic circuits, you've probably already discovered that there's no really simple way to debug them. At first glance, this may seem surprising. One of the nice features of logic is that you don't generally know or care what the exact voltage level at a test point is . . . only if it's high or low, a logic 1 or 0. As a matter of fact, a cheap VOM is quite adequate for static logic, and a dc scope is even better. Since the voltages aren't important, a circuit using an LED which lights for a 1, and is unlit for a zero, is great, and for $20 to $200, depending on your tastes and budget, you can buy one of several clip-on probes that will display the logic level on each pin of a 14- or 16-pin DIP. The better ones don't even need power - they locate and draw from the supply pins of the IC itself.

The problem is that most of the interesting logic circuits aren't static — there are all kinds of pulses flying around, and it's usually these pulses that are the important factors. Worse yet, they don't always come at regular time intervals, so you can't sync them in on an inexpensive, repetitive-trace scope. Even if you could, you may not be able to see them. TTL logic can respond to pulses that can't be seen on any but the fastest scopes. One trick I've seen is to use a triggered sweep scope, with the threshold set so it normally doesn't sweep. When you get a sweep, you still can't see the pulse, but you know something pulled the trigger (of course, it could have been your wife's hair dryer). Aside from the obvious overkill of using a $3000 scope to check out a handful of 20¢ gates, this method is not too satisfactory. The setting of the threshold is tricky, especially if there are other pulses around, and you still never see that pulse.

Straight LED indicators are no better. While the response time of an LED is very fast, that of your eyeball isn't. As it turns out, the human eye can see surprisingly short pulses of light, under the right conditions, but it has a long retention time. This means that in a darkroom, you *may* see that LED flash on; you'll never see a lit LED flash *off*.

It looks like what this country needs is a good $20 logic probe that can see pulses of either polarity, as well as static levels, and display the situation to you in a way that can't be misunderstood. The Eico DLP-6 is an LED probe that fills the bill. The key feature is a pulse-stretcher that detects positive- or negative-going pulses as short as 50 ns, and gives you about a half-second flash on a pulse LED. In this respect it's similar to Ted Lincoln's circuit (*73*, Aug. 76, pg. 106). It also has LEDs for both high and low static levels, which permit a feature I haven't seen before — it can tell the difference between an active high or low, and an open circuit. This can be really useful. As a final touch, the three LEDs are different colors (red, green and yellow), so unless you're color blind, it's pretty hard not to get the message.

The DLP-6 comes in a bubble pack, complete with a small plastic carrying case. All parts mount on a narrow PC board, which slips inside the body of the probe. Assembly is quite straightforward and takes about an hour. The instructions are no Heathkit manual, and there's one error in one of the figures, but in general everything went together as intended. Eico says to use the green LED for the "high" indicator, and red for "low." This seemed backwards to me, so I reversed them. The LEDs seem to be interchangeable, so use your own color scheme. If you make up your mind *before* soldering them in, you may not burn them up removing them as I did! (LEDs are more sensitive to heat than ICs, and these have to mount absolutely flush with the PC board or you won't be able to get it into the probe body. A power cord comes out the back of the probe, and is terminated with alligator clips. Yes, Virginia, the probe needs external power. You didn't think you were going to draw power from the chip with just the probe tip, did you?)

In operation, just connect the two alligator clips to any source of five volt power and ground, and you're ready to start probing. The three-color system is very easy to read, and after a little practice you can get quite a bit of information from those three lights.

Recently, I had occasion to use the DLP-6 to find a bug in my TVT-II. I had been trying for two days to find a missing pulse, before it slowly dawned on me that the pulse was so short I wouldn't be able to see it on my scope even when I "found" it. Using the DLP-6, it took about fifteen minutes to find a NAND gate with positive pulses in on all inputs, but no negative pulse out. Aha!

As a matter of background, the circuit used in the DLP-6 originally appeared in *Popular Electronics* (Richard P. May, March '74, pp. 33-35), along with a PC layout, so apparently both are in the public domain. Buy it or build it, but try it; you'll like it!

THE KLM MULTI-2700 ALL MODE TRANSCEIVER

With interest in OSCAR mounting, and SSB activity up on 2 meter FM, it was inevitable that someone was going to come up with a do anything/everything transceiver. Now, KLM has. It's the new Multi-2700 . . . with OSCAR Mode A, upper and lower sideband, WBFM, NBFM, AM and CW all stuffed into one 28 lb. package.

When KLM introduced the Multi-2000 some years ago, it was in a class by itself. Then came Kenwood's TS-700A and the Yaesu FT-221, and the VHF sideband boom was on (commercially speaking). But no one offered the best of both worlds . . . it was either a synthesizer or VFO . . . no combinations. OSCAR work still required a separate receiver and transmitter, but SSB activity on the satellite sure came up.

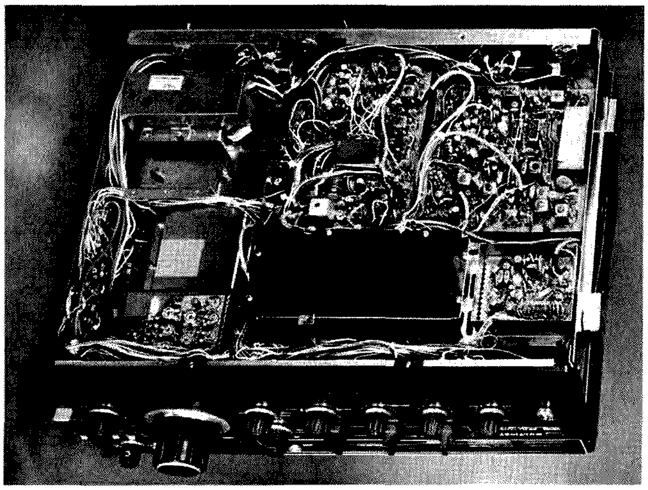
The next step was to put it all in one package. With Mode A in mind, KLM's idea was to synchronize 29 MHz receive with 145 MHz transmit, while maintaining a constant 116.45 MHz difference between them. Using the synthesizer and VFO you can work through the satellite or monitor beacon signals at the flick of a switch. Because the Multi is a transceiver, however, the big difference between normal OSCAR operation and using the 2700 is that you can't monitor your relayed signals from the satellite. One then has to rely on the beacon signal (received separately on the synthesizer). As long as you can hear the beacon, you can work the satellite. KLM has left room for Mode B work, with a 450 MHz converter coming to fit into internal terminals. (50 MHz converters are also planned.)

The Multi-2700, in a word, is loaded. There's an 8 pole SSB filter, two FM filters, VXO and RIT, LED readout on the synthesizer, audio speech compression, ac/dc power supply, separate output and deviation meters and VOX. The VFO setup features a 5 to 1 tuning ratio, with the inside knob going 20 kHz per revolution and the outer knob going 100 kHz.

All that costs money, of course, and the Multi's price tag reflects it. But at $799.95 KLM's newest is not out of the price class for all-mode VHF gear. At that rate the OSCAR capability, hear your own signals through the satellite or not, is a bonus.

Operating the 2700 is pretty simple, and with only a vertical both SSB stations and repeaters could be worked quite adequately. Working OSCAR, however, takes a bit more practice with the VFO and synthesizer. Availability may be an initial problem; as we go to press only 25 units have reached the states, but a KLM spokesman says production should be up substantially by the time you read this.

A clean layout — with VOX, AGC and gain controls accessible through top port.



The "guts" view – note 29 MHz receiver, upper left, and space for plug-in 450 MHz unit below.

NEW 1977 RADIO SHACK CATALOG No. 276 NOW AVAILABLE

Radio Shack's new 1977 Electronics Catalog, featuring its exclusive line of products for home entertainment, hobbyists, CBers and experimenters, is now available from Radio Shack stores and dealers, nationwide.

The all-new 164-page catalog includes 100 full-color pages describing the company's complete line of products. Prices in the new catalog, which marks Radio Shack's 56th year in business, are reported to be, on the average, within 1% of the company's average 1975 prices.

Among the new items introduced in the catalog are: eight new stereo FM/AM receivers, led off by the Realistic STA-2000 75 Watt per channel receiver, the Optimus T-100 Tower speaker system, the new LAB-300 turntable and several new stereo tape cassette recorders.

Radio Shack is also introducing an all-new line of pocket calculators ranging in price from $10.95 for a 5-function model, to $39.95 for a scientific slide-rule calculator.

Other items featured in the catalog include: Realistic-brand CB two-way radios, automotive tape players, portable radios and scanning monitors, Archer antennas, Micronta test instruments and ArcherKit and Science Fair electronic and hobby kits.

In addition, the new catalog lists hundreds of specialized electronics items, parts and accessories, tools, tubes, semiconductors, wire and cable, home security products, intercoms, microphones, timers, batteries and a complete library of Radio Shack's own books on electronics and related subjects.

The catalog also includes bonus coupons good for a 50% savings on the company's own Supertape and Realistic brands of tape, and a coupon worth $1.00 on the purchase of their $1.25 book, *All About CB Two-Way Radio.*

In announcing the new catalog, Radio Shack president Lewis Kornfeld stated: "That great old American institution, the Radio Shack catalog, has just been published again, entirely revised, available in all our stores, and still free! Free to you. To us it represents an investment over $3 million.

"The total printing comes to 2,132,000,000 pages," Kornfeld continued. "Stretched end to end: 1,777,777,777 linear feet or 336,700 miles, or 13.525347 times around the world at the equator. The new 1977 edition consumed 3787.5 tons of paper and 1,222,000 pounds of ink. These statistics are revealed to discourage our competition. And to give cheer to America's postmen who don't have to deliver the catalog since none are mailed – you'll have to get your copy at one of our stores."

NEW VIZ FREQUENCY COUNTER USES PRECISE CRYSTAL-CONTROLLED TIMEBASE FOR EXCEPTIONAL ACCURACY

VIZ Manufacturing Company has introduced a frequency counter to its growing line of test instruments. The WD-752A counter is designed for making frequency measurements between 10 Hz and 60 MHz in audio, video, CB, ham radio and other communications equipment.

A unique feature of the counter is its 1 kHz audible sidetone with separate on-off volume control. The 1 kHz tone is valuable in modulating single sideband transceivers for carrier frequency measurement. The counter has a selectable input sensitivity of either 10 or 100 mV; the lower sensitivity is valuable when considerable noise is present with the signal.

The counter uses a carefully selected 10.000 MHz crystal to create an extremely accurate timebase, ensuring the accuracy of the 10, 100 and 1000 millisecond gate signals and logic control. The measuring circuit is composed of a six-state IC counter which feeds into a very bright readout made up of six 0.3" seven-segment LEDs. The frequency, decimal point, and range (either MHz or kHz) are all displayed automatically. A signal lamp indicates when the signal is sufficiently strong to be counted and indicates when the higher sensitivity input is required. An overflow lamp indicates a signal that exceeds 1 MHz when using the 1 second fixed gate.

The BNC input is compatible with most standard broadband oscilloscope probes. When making measurements of transmitter or transceiver AM frequencies, the counter is positioned near the transmitter and a one meter cable attached to the input serves as a pickup antenna. The counter can also be attached directly to a transmitter or transceiver with a directional coupler and dummy load.

The counter operates on 115 V ± 10 V, 50/60 Hz. The unit is extremely compact, measuring only 2-5/8" x 5-3/4" x 9-1/4", and weighs only 4 lbs. The dealer optional price is $255.00.

Further information on the WD-752A frequency counter is available from Bob Liska, VIZ Test Instruments Group. *VIZ Mfg. Co., 335 E. Price St., Philadelphia PA 19144, (215)-844-2626.*

NATIONAL'S NEW VOLTAGE REGULATOR HANDBOOK

It would be difficult to find a handier guide to voltage regulators than National Semiconductor's latest release. The handbook is chock-full of great circuits, theory and seemingly endless specs on not only National's line, but comparison data on the competition as well.

It truly is a handbook, since the opening pages cover power supply design basics, transformer specifications, rectifier circuits, filtering and load effects. But that's not all. Heat flow and thermal resistance theory get their due along with heat sink design and applications.

At $3 a shot (California residents add 6% sales tax) the *National Voltage Regulator Handbook* is a heck of a value. Send your check to National Semiconductor Corp., Marketing Services Department, 2900 Semiconductor Drive, Santa Clara CA 95051.

THE SENCORE F-14 FIELD EFFECT METER

Like most hams interested in construction and troubleshooting, I have become accustomed to having two types of meters to fill my needs. A 20k Ohm VOM was used for portability, general testing and, most essentially, for current measurements. A VTVM was also a must for high impedance voltages, and with an accessory probe for rf measurements. Redundancy was unavoidable since both types of meters offer duplicate capabilities in some respects, while each possesses its own uniquely desirable features.

A recent drive to improve the station test facilities, and a searching review of the latest products, led to the acquisition of the Sencore F-14 Field Effect Meter, which succeeds in obsoleting both of my original meters.

Of particular interest to hams is the fact that the F-14 packs all the desirable features of a VOM and VTVM into a single unit. Field effect transistors replace the functions of the traditional vacuum tubes, providing better characteristics than the VTVM, without the need for ac line power. And, in addition to 7 ranges of ac/dc volts and 5 resistance ranges, the F-14 also measures dc current in 5 ranges from 100 uA to 1 A full scale.

Special features include: very high input impedance; 15 megohms shunted by 14 pF on dc volts; 10 megohms shunted by 29 pF on ac volts. Ac volts provides a broad bandwidth from 10 Hz to 10 MHz at 3 dB points without an accessory probe. The meter face includes scales for ac peak to peak voltages, a zero centered, plus and minus volts for servicing contemporary solid state circuitry, and a mirrored strip for optimum readout accuracy. Positive meter overload and FET circuit protection is incorporated to guard against incorrect voltage application.

The F-14 instruction manual includes construction details for some simple adapters to further increase the flexibility of the unit, such as a plug-in shunt to extend dc current measurements to 10 A, a switchable shunt for ac current ranges of 1, 3 and 10 A, and the accurate measurement of very small dc currents encountered in transistor, diode and capacitor leakage, in the order of nanoamps (0.001 uA).

This little gem weighs in at less than 3½ lbs. with batteries, and occupies about half the cubic space of the average VTVM, with a large 4½" x 3" meter face. The rugged all steel case is vinyl covered for an added appearance touch, and practical protection. Batteries required are standard types available at any drugstore or supermarket.

On the bench, in mobile or portable applications, anywhere you need to use it, the F-14 is instantly ready at a flick of the switch, with no warm-up period for stabilization. Oh, yes! I found some industrial type solid state meters in the catalogs offering similar capabilities – at about twice the price of the F-14.

General Description

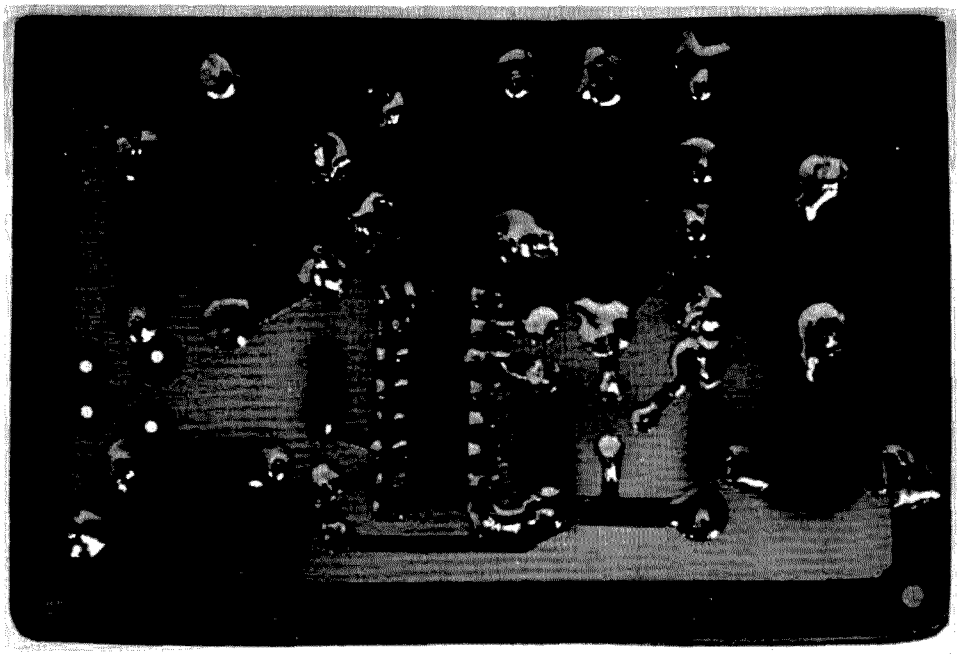
Meter: 4½", 100 uA, ±2%, diode protected and isolated from input.
Multiplier Resistors: 1% precision type.
Ohms Battery: 1.5 V "C" cell, Eveready type 1035 or equiv.
Power Supply Battery: 9 volt, Eveready type 222 or equiv.
Weight (less batteries): 3¼ lbs.
Dimensions: 5" W x 7-3/16" H x 3-1/16" D.

Peter A. Lovelock W6AJZ
Santa Monica CA

The increased population of amateur repeaters and the resulting interference has forced many repeaters to use tone access systems. The tone burst system is irritating to users, and if a station drops out after accessing the system, there is no way for the system to be reaccessed until the next transmission. These factors led to the unit described in this article. The cost of reeds for a reed encoder is prohibitive for most amateurs ($15 for a new reed plus another $15 for the encoder), while this complete circuit can be constructed for approximately $10.

Circuit Description

The unit (see Fig. 1) is a simple crystal controlled oscillator[1] driving a CMOS



PC board.

Go Tone for Ten

-- simple subaudible encoder

Carson Haines Jr. WB6GON
3112 Sylvan Ave.
Oakland CA 94602

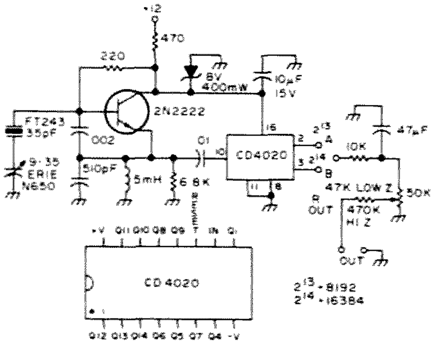


Fig. 1. Subaudible tone encoder.

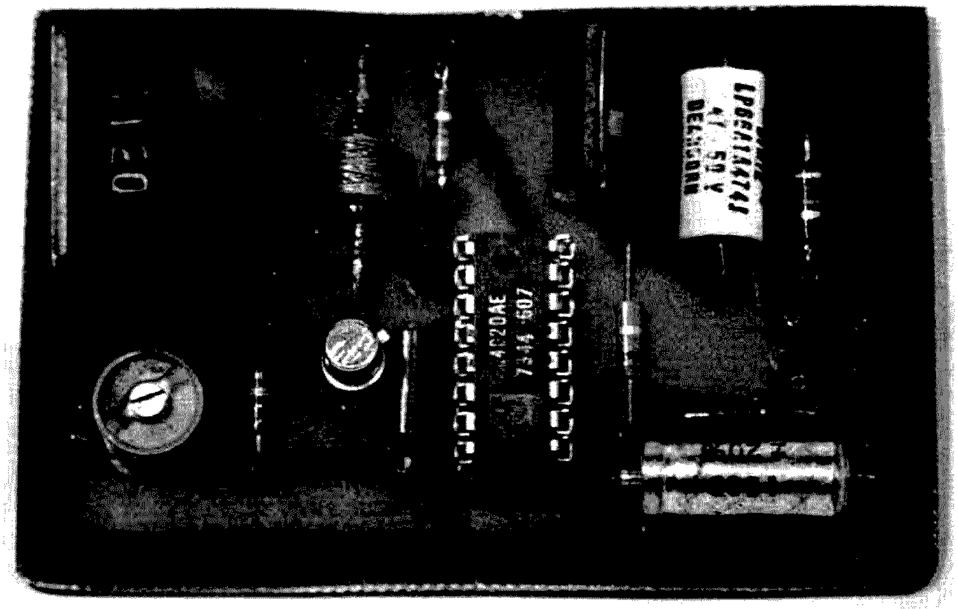

Component layout.

divider with an RC filter on the output. The CMOS divider was selected so the number of components could be reduced from four 7490s and a precision voltage regulator to one CMOS divider with a simple zener voltage regulator.

In the units constructed, FT243 crystals were used. To calculate the frequency of the crystals, see the sample below:

Required Frequency x Divide Ratio = Crystal Frequency
Example: 136.5 Hz x 8192 = 1.182 MHz

There are two divide ratios on the board, 8192 and 16384. If other frequency range crystals are available, simply bring out the required divide ratio from the IC and feed it into the filter. The crystals used in the original units were the least expensive crystals Jan Crystals had listed in their catalog. Pick a crystal frequency as close to the calculated value as possible. In our units for 136.5 Hz the closest crystal was 1120 kHz. This yielded an error of .2 Hz when the dividing was completed, and normal reed decoders are approximately ±1 Hz wide minimum. When selecting a crystal, try to keep the end error to approximately .5 Hz and you should not experience any problems. The oscillator is very broad band and crystals from around 100 kHz to 3 MHz should perform fine.

The dividing is done by a CMOS divider and it is available from Godbout Electronics. The CD 4020 has divide ratios of 2 through 2^{14} (16384) available and if other ranges of crystal oscillator frequency are used, it is possible to pick the divide ratio you require.

The output circuit is a simple RC filter[2] which takes the square waves on the output and makes them into a triangular waveform. The potentiometer in the output is used to set the output level, and the resistor value for the series resistor should be selected for the impedance into which you are inserting tone.

Construction

The unit can be constructed using any means available. The original units were constructed on PC boards and a full size layout is included (Fig. 2). Parts value is not critical, so select parts you have on hand that are near to the values listed on the schematic. The zener can be between 6 and 9 volts since the CD 4020 will run on any voltage between 5 and 15 volts.

Operation

Connect the unit to a source of 12 volts that is turned on when the transmitter comes on or let the unit run all the time (only 10 mA is required). Connect the audio and you are ready to go.

I will be happy to answer any questions you may have regarding this unit, but please SASE or no answer. ■

You kind of coax the rope through the pulley, eh?

ADAPT OR PERISH

In your I/O editorial in the Oct. 76 issue of *73*, you wanted reader response to the content of *73*. Here's my 2 cents!

I have at one time or another subscribed to just about every ham magazine (yes, even *QST*). I presently subscribe to *73* and *Ham Radio*.

I have heard some OTs say that hams don't build anymore. They're wrong! There is more building going on now than ever before in ham history. True, we don't build receivers and transmitters like our grandfathers did, but then why should we? We can buy an excellent transceiver for a price for which it couldn't be built. It's downright stupid to build a receiver for $200 when you can buy it for $100. But I'm getting off the track. Suffice it to say that *73* is geared toward the builder. *QST* is not. I believe that *QST* is trying to please every ham all the time. If you want to read 16 pages of contest results, then by all means subscribe to *QST*. *Ham Radio*, on the other hand is an excellent magazine for the builder. But, and a big but, *HR* is not geared toward the average ham. The steelworker or autoworker who puts in a hard 8 every day doesn't have time or patience to get into anything too deeply. If I have some knowledge on a topic, I can usually follow an *HR* article. But when I'm completely ignorant about something, I look it up in *73*. That about says it.

A few words about the I/O section of *73*:

I think along with myself, most experimenters are baffled by all the I/O articles and ads. There's a lot of stuff for sale, but we don't know what to do with it.

At first, my opinion was that I/O material didn't belong in a ham radio magazine. Maybe it does or doesn't, but let's go back about 6 years ago. Back in 1970, something called TTL ICs were being advertised here and there in all the mags. We wondered what they were good for and why computer surplus should be in a ham magazine in the first place. Well, here we are just six years later and we can't live without the damn things. ICs do things cheaper, quicker and easier than any other means. They do things that couldn't practically be done any other way. Sure, I struggled for a few years buying ICs I didn't need, making mistakes (I still make them, but not as often), and building projects that never worked. We all have.

The point is this: Right now, I can't see a microprocessor in my future, but six years ago I didn't see why anyone needed a frequency counter. Boy, how wrong we can be. Wayne, I want you to know that even though I have been in electronics for 15 years, I am struggling through the I/O articles. I have to read them 2 or 3 times and they still don't make sense to me sometimes. I'm learning, not much, and not fast, but I'm learning. Keep cramming that stuff down our throats whether we say we like it or not. If you don't, who will? Certainly not *QST*. *HR* is already over most of us. Don't give us a magazine full of CB construction projects, because six years from now we'll wake up and find that the world has passed us by. I don't understand most of the I/O articles, but someday I will. At one time I didn't know the code. Now I do. That's life. To survive you have to adapt or you perish. I'll bet my grandfather had just as much trouble understanding a crystal detector as I have understanding a PROM. It didn't stop him and it won't stop me. Keep printing the I/O stuff and I'll keep struggling with it. Stop printing it and we'll all be crushed in modern technology.

Paul J. Dujmich WA3TLD
McKeesport PA

Ok, ok — I'll print it, I'll print it. — Wayne.

NOT PROPER

Several recent events have prompted me to write this letter. It concerns operation on two repeaters in Dallas on 147.36 and 147.39. Some of the operation I have witnessed on these two frequencies I do not believe to be in the spirit of amateur radio, and responsible operators in the Dallas area need to take note.

The repeater on 147.36 is listed in repeater directories as OPEN. Several of the group's members have personally told me that it was OPEN. Recently, as I was calling a friend of mine on .36 (my friend is a member of the group), I was asked to leave the frequency at once by a ham who heard my call. He said that he personally did not like me (I do not even know the man), and that anyone with intelligence knew that the repeater was CLOSED.

The repeater on 147.39 is a closed, private repeater. This group seems to be unable to tactfully get that point across. When I first got my synthesized rig, I did not realize that closed repeaters existed. I keyed up on .39, gave my call, and asked if anyone were around. My call was answered by a ham who said that it was a closed repeater and that outsiders were not allowed on frequency.

I believe that such operation is not proper in amateur radio, and that it can be greatly detrimental to our hobby. Hams who are concerned about keeping amateur radio as it was meant to be, should take a close look at these problems and others like them.

Blaine Hamrick WB5LSJ/WR5AKL
DFW Airport TX

NASTY WARNING

Regarding the interesting article "Have You Used a Triac Yet?" published in *73 Magazine* for October 1976 at page 76: I think a warning might be in order.

If a high voltage transformer were used as shown on page 77 with the resistor/capacitor across the triac, a person believing the triac "relay" to be open, and working on the power supply, might get a nasty shock, especially if the capacitor were larger than that shown.

I continue to enjoy *73* very much — keep up the good work.

Bill Allen W1LU
Providence RI

A little shock might be good for some of these five volt TTL kids.

COMM-ED

I noted the comments about Trigger Electronics. Let us not forget another company known as Dycomm, or Dynamic Communications, Inc. of Florida.

More than two years ago, after a phone conversation with Jim Penny, I ordered a front end crystal filter for my 81-21 repeater in Whitmore Lake. Upon arrival, I was astounded at its physical construction, being in a non-rf-tight minibox. Checks using professional Hewlett-Packard and Singer test equipment showed that it did not provide the 5 dB gain and sharp selectivity claimed, but in fact provided considerable loss with multiple response (passed more than one frequency). So much for $75. I sent the unit back and asked for one that worked or a refund. Months went by and no answer; finally, another phone call, and I explained the problem. Still no refund or unit. Now, more than two years has passed, and I have never received the unit or a refund. Insomuch as the repeater was moved to a nearby town and the equipment has changed, I have no need for a new unit. But my creditors sure could use the $75!

I also had a lot of problems with the various amplifiers they sold, too!

Henry Ruh WB8HEE
Whitmore Lake MI

MORE 20777

After reading "Belt Tightening" by Donald Chester K4KYV/1 in the July issue of *73*, I agree very much with him regarding AM and NBFM usage. These are about the cheapest means a ham has at his disposition to get on the air on voice on HF. Let us keep in mind that not all of us can afford to throw $600 on an SSB set. Besides, quite a number of foreign hams still use AM phone.

On one point I heartily agree with Docket 20777. I'd love to have back A-2, T-5, MCW on the HF bands.

Benjamin Lamboy KP4CA
San Juan, P.R.

ANGER TRIGGERED

Just a word of sympathy for Horace WA4CUD and Larry WA4MJA, along with the many others "shot down" by "the Trigger man."

It seems to me we can do nothing with this company as individuals. Perhaps you, or some of our "ham" friends, could come up with something we could do collectively. This company is "in to me" to the tune of $80, and I do not like the music they play.

Have tried the BBB (no luck), and am going to the Attorney General of New Mexico. Also have a file with the U.S. Postal Service.

Any other ideas would be appreciated. This company must be stopped.

Raymond E. Boshart WB5ROP
Box 1041 (712½ Ivy)
Truth or Consequences NM 87901

Trigger may soon be sent out to pasture — or else stuffed and mounted.

LEARNING A LOT

Just a short note to encourage you to keep printing everything about computers you can get your mitts on in *73*. At first it was all a mystery to me and I wondered what I was getting in my magazine, but once again (last time was 2 FM) I trusted you and, as a

direct result of *73*, I now eat, sleep and breathe computers. I am slowly stashing pennies, but it will be at least a year before I can assemble a system so I will have to read, learn and dream in the meantime. Please send me a year's subscription to *Kilobyte* and bill me before I change my mind. I am sure most of it will be above me, but like *73*, when my interests change or I become more knowledgeable, I would like to have the back issues to look through. I am in the electronic security business and will have a few articles forthcoming soon. I wish I could trade alarm stuff for computer stuff. Guess I'll have to use the money substitute being eroded by the government in the meantime — convert my alarm talent into a fascimile of a federal reserve note and later swap the note to someone for computer stuff. The government is trying to protect too many people. I'm tired of them trying to protect me. I have been buying kerosene in plastic storage bottles (government issue) for many years. Now it is illegal for me to purchase or store it in anything except metal. The government is protecting me.

Another subject . . . The secrecy of communications act. Several of my customers have silent holdup alarms in stores, banks, etc. These alarms call the police silently when they have a problem. Last week two of these alarms were tripped. I heard the call on the police monitor. Within 5 minutes my customer was on the phone wanting to know why the local newspaper had called wanting to know if they had been held up. This seems to me to be in violation of the act. My customer's life would have been in jeopardy if there was in fact a holdup taking place when the newspaper called. If the holdup man had answered the phone, I probably would have lost a customer and friend. The paper's employees sink hundreds of dollars into police monitoring equipment in their offices and cars to assure that they will be instantly aware of crimes and traffic accidents that are happening and be able to rush a photographer and reporter out. Nuff said. Thanks, Wayne; I'm really learning a lot from *73*. It's almost like an inexpensive and highly entertaining college course. Especially liked the articles about BASIC in the October (!) issue. All the I/O editors are great. If I can help in any way please feel free as always . . .

Steve Uhrig WA3SWS
Ellicott City MD

THE QRP CHAMP

K5JRN's QRP transmitter ("QRP Fun on 40 and 80," October '76) works like a champ. It was up and running into a random longwire two days after the magazine was received. My first home-built transmitter, 12 contacts so far in four days on mostly 80 meters . . . VA, DE, CT, and a 599 from MA. On 40, one contact in TN and IN albeit poor due to the frequency of 7148.5 fighting it out with Radio Moscow on 7150. I'm waiting for my General and I look forward to moving outside of the QRM-loaded Novice bands.

Thomas R. Sundstrom WB2AYA
Willingboro NJ

GOOD BUY!

Compliments. I have read many professional and hobby magazines, and I must admit *73* would be a great buy at twice the price. Each issue has lots of meat in it for many interests. Keep up the I/O section. I'm not into computers but I know I will be sometime in the future.

Kent H. Gibb VE6BAF
Edmonton, Alberta

Twice the price . . . hmmmm?

BEST IN THE WORLD?

My subject is Atlas Radio Company, headed up by Herb Johnson and his boys. I bought an Atlas 210X and had trouble with it; I sent it back and then it developed more troubles. One day I wrote a letter to Herb Johnson and explained the troubles. About two weeks later the UPS had a package for me from Atlas Radio. Yep, you guessed it; it was a brand new Atlas 210X, and as soon as I got the chance, I tried it out. It was hotter than a firecracker and some of the QSOs I had were as strong as a base station. You see, I am trying to get Bicentennial WAS from a car, and that is quite difficult with a wet noodle for an antenna and just 100 Watts output. I believe that there is not any other ham radio manufacturer who would do what Herb Johnson did, and I believe that Atlas Radio is the best ham radio company in the world.

Russell "Bud" Holderbaum, Jr.
W3AEZ/W4JIQ
Gaithersburg MD 20760

TRUTH OR CONSEQUENCES

Thanks for the latest *73* addition, the hard copy reader service card.

Keep up the IC projects. I built the HR-212 on page 66 of the May '76 *73* mag. The article says to scan 6 channels, but without any mods using 0 for 8, up to eight channels can be scanned. Also, by adding an AND gate, ten channels can be scanned. Works FB. Oh! By the way, would like to see a small article on how to make the HR-212 hang in there (delayed scan) on active channels. Also a source for printed circuits to be used with the articles!

I see for the last 2-3 months ads missing from Altaj Electronics, Dallas. I ordered their King clock and only after 4-5 weeks delay and two telephone calls, was able to get delivery. But since then, I have done business with them and have gotten prompt, courteous service. James Electronics is another story. They have *same day service*. So far I've placed 2 or 3 orders with them and have gotten them back (including postal time) within six days. FB!

How about mentioning the *Fox Tango Newsletter* put out by The International Fox Tango Club, Milton Lowens WA2AOQ/4, 248 Lake Dora Drive, W. Palm Beach, Fla. 33411 at S5 per year (10 issues). Its sole purpose is the exchange of info, mods, etc., for Yaesu owners — a terrific letter. Well, that's it for now.

Tom Gundlach WB5JDU
Truth or Consequences NM

MORE IN THE FUTURE

About your article "QRP Fun on 40 and 80" (Oct. 76) by Si Dunn K5JRN. GREAT! I thought that I had to buy all of the old radio mags to find this kind of make-use-of-your-junk-box gear. Hope to see more in the future. This type of article makes ham radio a challenge.

Terry D. Wright
WB8UPO/ADM8UPO
Piqua OH

MORE OF THE SAME

The article by Gabriel F. Gargiulo (October, pg. 128) was the best on programming in this issue, I thought. It was very clear and instructive. Also, your I/O editorial points out the computer's potential. Let's have more of the same.

Ken McGinnis
San Mateo CA 94401

PLAIN ENGLISH

I wish *73 Magazine* would (for once) show a construction article which was written in plain English! Terms like TTL, PLL, coil phasing (in one article it said "The coils must be properly phased so the circuit will oscillate," but never mentioned what phasing means or how to do it). ½λ, etc., etc., make the average Novice's (or at least my) head spin.

You should put one article in each month's issue designed especially for Novices (simple and educational). I, for one, would like to design my own circuits for different projects, but can't because of lack of knowledge. These articles would help people learn theory and at the same time show them some sort of practical use!

L and C circuits always give me trouble. Figuring the proper value of L and C for different frequencies is murder when you're only an 8th grader (soon to be 9th grader).

I hope other Novices who see this (if you print it) will support this idea or improve on it.

John Halliwell
Hampton TN

P.S. I have 5-9 weeks to go before I get my Novice license. I love your magazine. Keep it up.
P.P.S. I want to mention that Optoelectronics is a great dealer. Their service was fast and their electronic clocks work great!

TEST PILOTS ONLY

Nearly every issue contains subscription offers for expanding *73*. I would like to propose another way in which new blood can be brought into the fold. Why not have a WN section similar to the I/O section that will teach us neophytes the basics of building the kinds of ideas that the more advanced hams submit?

After people see that top-notch authors are penning stuff they can read, they'll run out and hopefully get a life's subscription.

I would also like to see an article to review 2 meter operations and a few on uP fundamentals.

James Wessels, Jr.
Louisville KY

Sure, James, I'd love to have more articles on fundamentals for Novices, but life subscriptions are going to be permitted only to amateurs over 73 years old who are full time test pilots. Some readers think we've already run enough 2m operations articles, but there sure is a thirst for uP material. — Wayne.

ANOTHER CHARTER

I was unable to give you my subscription to *Kilobyte* at the computer convention this past weekend.

After seeing how well you started *Byte Magazine* out, I am sure your latest venture will be as good or better.

Please accept my subscription to *Kilobyte* for a three year charter membership. Enclosed is my check for S25.00.

Carl G. von Loewenfeldt
Alexandria VA

KING AND QUEEN

Just a few lines to let you know that Lloyd Colvin W6KG and Iris Colvin W6DOD have returned to California, via Australia, Western Samoa, American Samoa and Hawaii, after a

Continued on page 39

Complete five band dual conversion amateur communications receiver.

I am sure many radio amateurs who have home brew rigs would love to have a matching receiver. Deciding to do something positive about this emptiness in the shack, I came up with a plan that made the home brew receiver not only a possibility, but a reality.

The plan centered on reducing the complexity and time of construction dramatically by using a drugstore transistor AM broadcast radio set as the main building block. Even if you never start to build this receiver, I am sure that you will find it comforting to know that if it ever became necessary, you could do it.

This receiver, being a dual conversion type, has two local oscillators (LO) and two intermediate frequency amplifiers (IF). In this circuit we have to make our own HF LO, while both IF amplifiers and the MF LO are parts of the AM broadcast set.

We also have to make six other circuits to support our BC set to make certain that our project winds up a real communication receiver. These are the HF radio frequency amplifier, 1 MHz amplifier, beat frequency oscillator (BFO), S-meter, crystal filter, and automatic noise limiter (ANL).

When all the circuits are working together, their operation is spectacular for such a simple design. When the rf gain control is two thirds up, a 0.2 microvolt 7.1 MHz signal at the antenna connector will read S9. The receiver noise is too low under these conditions for me to make a measurement with the simple equipment available to me.

All I can say about it is that I could hear only signal in the phones, and I just finished working F6ARC on 40 meters with no trouble at all. Any dual conversion birdies are less than S2 and located so they are no bother.

Drift and broadcast station feedthrough is nil. Each of the five bands can be selected by a front panel control and is 0.9 MHz wide. The 6 dB down bandwidth signal selectivity is 300 Hz with the phase control in the CW position, and 1.2 kHz in the SSB position. It is powered by a 9 V battery and the current drain is 30 mA.

World's Simplest Five Band Receiver?

-- using an AM transistor radio

Warner F. Stortz K3QKO
5122 Alberta Ave.
Baltimore MD 21236

Circuit Description

The transistor AM broadcast set just keeps on doing what it did before we bolted it to the front panel – changing .55 MHz to 1.6 MHz rf to sound at the speaker or phones – so there is no need to describe it any further. Fig. 1 shows how it works in our receiver and is supported by the outboard circuits. These will be described in

detail because each is unique in this receiver.

Starting from the antenna connector, Fig. 2, the bandswitch, S1, selects one of the rf transformers, T1-T5. They are broadband-tuned to the center of the desired frequency range. Therefore, all the signals in the frequency range selected appear at the gate of rf amplifier Q1. Here they are amplified as much as possible without adding noise to the output. By using a low noise MOSFET for this amplifier, the receiver signal-to-noise ratio is greatly improved.

To prove this point without a lot of rotten math, it is logical that if the rf signal is made greater, the following gain controls will have to be turned down to yield the same output that was present before amplification. If noise was not added in the amplifying process, all the frying sounds generated by these turned down stages will be much less.

The output of the rf amplifier is inductive coupled to the gate coil of the converter transformer, T6-T10, and selected by the bandswitch, which, also through other poles, applies this signal to gate 1 of the HF converter Q2 (along with the HF LO output to gate 2).

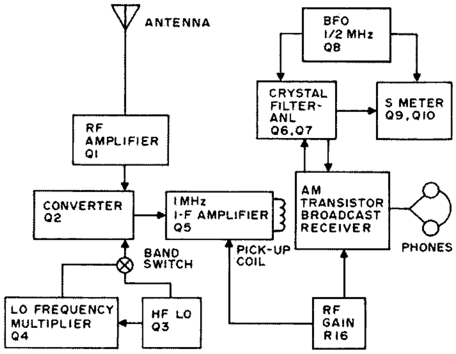

Fig. 1. Block diagram.

The HF LO is crystal controlled for stability and uses FT-243 type crystals. The 20 meter, WWV, and 15 meter bands are at a frequency higher than that at which these crystals will oscillate, so a multiplier is used to double or triple their fundamental output when the bandswitch is in these positions. This multiplier is a class C amplifier whose output is tuned to the selected frequency with rf chokes and fixed capacitors.

Now things really start to happen. While the converter Q2 is doing what is natural, its output is a real mess of signals, and we are only interested in the ones that are the difference between the LO and rf frequencies.

The unwanted signal that will cause the most harm is the very strong one at the LO frequency. If it gets into the BC set loop stick, overloading will take place and there will be birdies all over the bands. To stop this LO feedthrough, the converter output is filtered by using a well shielded oscillator coil, T11 (Fig. 3), removed from another BC set, and tuning it with a fixed capacitor to about 1 MHz.

Because of a long coaxial cable run to this improvised transformer, Z1 was fabricated to swamp any VHF parasitics that might develop. The base of the 1 MHz amplifier Q5 is connected to the pick-up coil in T11, resulting in a clean converted signal being amplified. It produces a strong field around rf choke L8, which is tuned to about 0.8 MHz with fixed capacitors.

This choke is mounted close to the BC receiver loop stick so its field will be picked up with little attenuation. Strong spurious signals (birdies) are unacceptable. Therefore, the importance of keeping the HF LO signal out of the BC set, and the BC LO signal out of the HF rf amplifier cannot be overemphasized. Most of the receiver shielding and parts placement was made to achieve this isolation.

The broadcast receiver is now able to tune and detect the different HF signals that have been converted to frequencies that are within its range. It is still not ready to be used for a reliable contact, because it needs at least a beat frequency oscillator and more selectivity.

The BFO is a series-tuned Colpitts type. It uses a transistor BC set IF transformer for the frequency controlling element and a front panel controlled capacitor to vary the pitch. Its output is taken from the small untuned winding in the IF transformer.

The receiver's fine selectivity is achieved by connecting a crystal filter between the collector of the BC set's first IF amplifier transistor and its output transformer. To implement this, the collector lead is disconnected from its original place, and reconnected through a coaxial cable to another identical IF transformer located on the ½ MHz crystal filter and ANL circuit board (Fig. 4).

This transformer, T12, provides the input for the FT-241 low frequency crystal Y6 and the 180 degree out-of-phase signal for the phase control C20. When C20 is critically adjusted from the front panel, stray signals shunted around Y6 are canceled and the filter output

Fig. 5.

has an extremely narrow bandwidth.

When it is closed, it sends a strong signal around Y6 and the bandwidth is useful for SSB communication. The output of Y6 is kept at a very high impedance and connected to gate 1 of Q6. Gate 2 has the BFO output and the ANL bias feed to it. The BFO is mixed with the IF in this manner to prevent strong signals from pulling its frequency.

The gain of Q6 is regulated by the amount of ANL bias at gate 2. Its drain is connected through another coaxial cable back to the BC set IF transformer at the original collector connection of the first IF amplifier transistor. This completes the IF amplifier circuit again, but with the crystal filter, ANL, and BFO added to it.

To develop the automatic noise limited bias, the IF signal at the input of the crystal filter is transformed to a low impedance by Q7 and diode CR4 changes it to negative dc, filtered by C24. This diode is biased to different values above cut-off by the front panel control R26.

When the signal exceeds this bias, a negative voltage is developed which is subsequently fed to gate 2 of Q6.

The gain of Q6 will vary with a noise pulse all the way to cut-off, depending upon the setting of the ANL pot R26. The diode limiters are also part of the ANL but they are not adjustable. The main function of CR1-CR2 is to prevent serious overloads from damaging any components when the transmitter is keyed, and that of CR5-CR6 is to prevent audio distortion.

The S-meter circuit has an unusual input network that nulls out the BFO component of the IF signal so it will not deflect the meter. This is accomplished by adding the exact amount of 180 degree out-of-phase BFO power to the input of Q9 (Fig. 3).

It might look like a marginal balance, but I have not had to change the original adjustment of R32, and a year has passed without the meter being slightly deflected by the BFO. The rest of the circuit is conventional with a voltage amplifier Q9 followed by a collector detector Q10 that deflects the meter.

The final two modifications require soldering inside the BC set. One is to add manual IF gain control to prevent overloading, and the other to stabilize the collector voltage that feeds the MF LO to prevent modulation and drift. To locate the

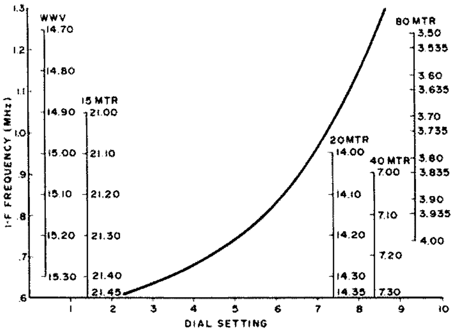

Fig. 6. Typical calibration chart.

proper place to do both jobs will take some looking around.

A zener diode, CR3 (Fig. 4), is connected across the large capacitor on the load side of the decoupling resistor feeding the collector power to the rf circuits. The resistor is about 100 Ohms and the large can type capacitor makes it fairly easy to locate.

Next you will have to find the forward biasing resistor of the IF amplifier base bias divider. My receiver has only one IF stage and it was no trouble to find. It will be about 150k and it feeds the power we just stabilized through the AM detector diode, which also doubles as the AGC generator, on to the cold side of the IF transformer base winding. This resistor is disconnected from the stabilized voltage and reconnected to the wiper of the front panel controlled rf gain pot, R16 (Fig. 3).

Construction

I assembled my receiver on a 15 cm x 10 cm x 5 cm (6 x 4 x 2 inch) chassis having a 18.4 cm x 12.7 cm (7¼ x 5 inch) front panel. The transistor AM broadcast receiver was selected because of its tuning dial and volume control layout. The negative side of its battery was connected to the ground plane, and the speaker opening was covered with a gold metal screen that would make a pretty good shield.

I found later that it had only one IF stage, but this certainly did not affect its sensitivity or degrade the project. The BC set must have extension shafts epoxied to its tuning and volume control dials so they can be operated outside the front panel. The new tuning dial is a vernier type and had to be mounted on a 1.1 cm (7/16 inch) homemade spacer so it would fit on the capacitor shaft.

The front panel controls, S-meter, speaker, and phone jack are located so that they are easily accessible. After the BC set has had its IF retuned to match the filter crystal, it is fastened to the front panel with two #2-56 bolts. One of the bolts has a solder lug under its nut so the BC set ground plane can be connected to the metal front panel through it.

The outboard circuits that convert the BC set into our communication receiver are made on pieces of "vector" breadboard material, and the components are soldered to press-in terminals. They were all made as small as possible and tested before they were mounted, using spacers, in the main chassis.

The bandswitch has two levels with three poles on each. All rf amplifier connections are kept on one level, with converter and HF LO connections on the other. A lot of effort was spent trying to keep the leads short and separated from each other, but it still turned out a mess. However, it works better than anyone could have imagined. I used #22 AWG solid insulated wire for the interconnections, and bare wire for the jumpers.

All rf transformers are mounted on the top of the chassis and are well shielded. The converter transformers are preassembled on a plate that fastens to a flange around a cut-out in one end of the chassis. These coils project into the underside of the chassis, isolating them from the rf amplifier input. The tuning is broadened by the heavy loading of both sets of coil with more primary (untuned) turns than would be used for high Q operation.

I used as much shielding as I could make without getting sick. It is very important to keep the outputs of the two local oscillators out of each other's converters, and the BFO harmonics out of the HF rf amplifier.

The cabinet is fabricated out of aluminum sheet and provides the shielding needed to keep out broadcast station signals. The front and rear panels are marked, after painting, with Datak dry letter transfers, and then sprayed with clear plastic to prevent them from being worn off. When the wrap-around top, bottom, and side piece is buffed carefully, the receiver has a professional appearance.

My semiconductors were selected because they were readily available to me. The SE 4010 transistors came from an old printed wiring board bought from a mail order house. When I ran out of these, I used 2N2222 transistors from another board.

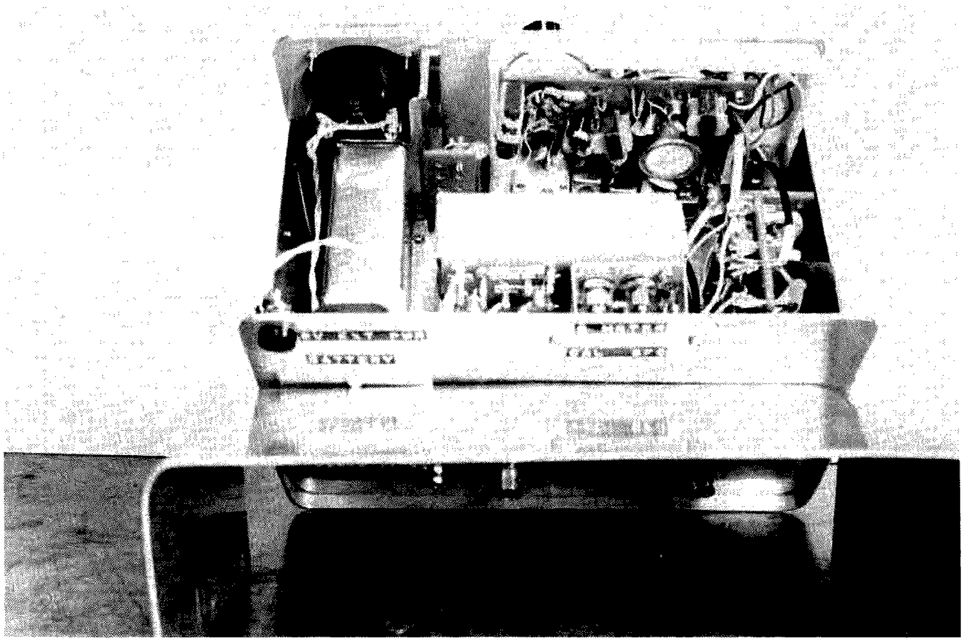

Fig. 7. Looking toward front panel with top half of cabinet removed. Top, left to right: S-meter, 1 MHz coupler next to loop stick antenna, AM broadcast set. Bottom: HF LO crystal shield, S-meter amplifier over the rf transformer shield, crystal filter and ANL circuit board.

Both are replaceable with Motorola HEP55, a NPN rf transistor.

The MOSFETs, Q1, Q2 and Q6, are the contents of a Radio Shack Archer Pack #276-628 called "Three MOSFET N Channel Transistors." You must watch how you solder these units in place. Keep all the leads shorted together during the process or the gates will surely be ruined. After they are in place nothing seems to be able to keep them from working.

Alignment

I aligned the tuned circuits of my receiver using equipment commonly found in the ham shack. Operation one is to tune the rf and converter transformers to the center frequency of their bands using a grid dip meter for an indicator.

Next, you must have the shields fastened into place, power switch placed on, rf gain turned fully on, audio gain one quarter up, ANL off, BFO off, phase capacitor fully closed, and the antenna input supplied with a signal from a VFO. The coupling must be very loose to the VFO.

The coupling recommended is two 50 Ohm resistors side by side, one fed by the VFO and the other across the coax connected to the receiver antenna terminal. There is no hard electrical connection between the two resistors (only the rf field), and the spacing between the two should be variable.

Back on the receiver, an oscilloscope is connected to the input of the filter crystal, Y6, using a high Z probe. The slugs in T11 and T12 are centered, and the bandswitch set to the VFO frequency range. The VFO or the receiver dial is varied until the rf is picked up and a ½ MHz IF signal is seen on the scope. T11, T12, and the rf converter transformer combination, when switched in, are adjusted until the IF signal is maximum amplitude.

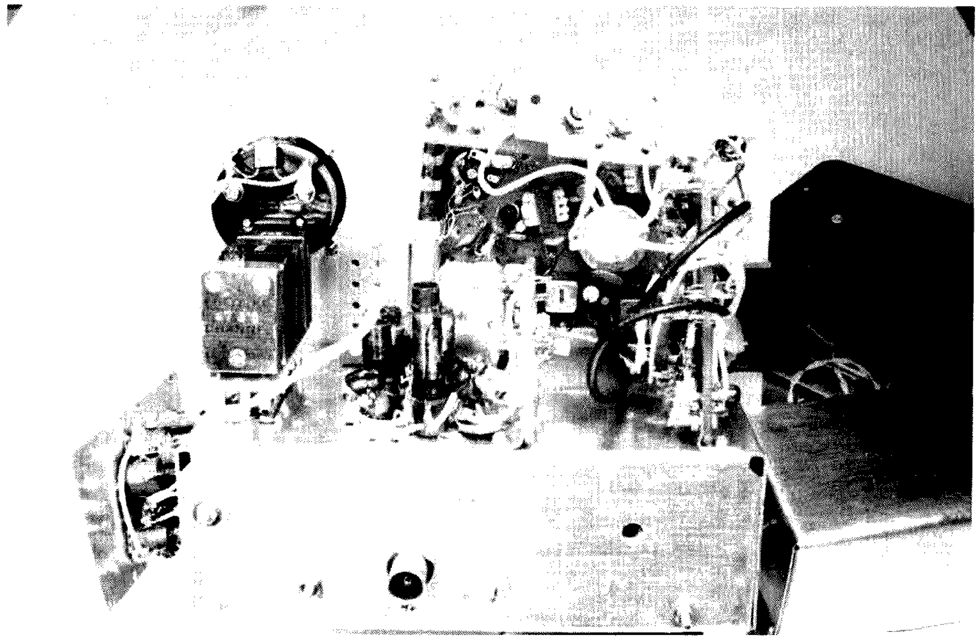

Fig. 8. Looking toward front panel with all shields removed, along with cabinet. Left to right: converter transformers on loose panel, HF LO crystals on home brew holder, 1 MHz coupler, rf transformers, rf amplifier, BC set, S-meter amplifier, crystal filter, ANL board.

The rf gain should be reduced along with the coupling to the VFO during these adjustments, to keep the scope presentation at an amplitude easy to see but not overloading the circuits (about a volt peak).

Connect the scope probe to the drain of Q6 and retune the receiver dial for a maximum display. Set the phase capacitor to its minimum bandwidth position, which is found by moving the VFO dial around the detected frequency. Move the scope probe back to the input of Y6 and tweak up T12 and the first BC set IF transformer so that their bandpass is centered on Y6's frequency.

Connect the scope to the output of the last BC set IF transformer and tweak up the remaining BC set IF transformers so they are also center tuned to Y6's frequency. The BFO is switched on, the pitch capacitor centered, and the slug in T13 adjusted for a zero beat, noted at the scope and the

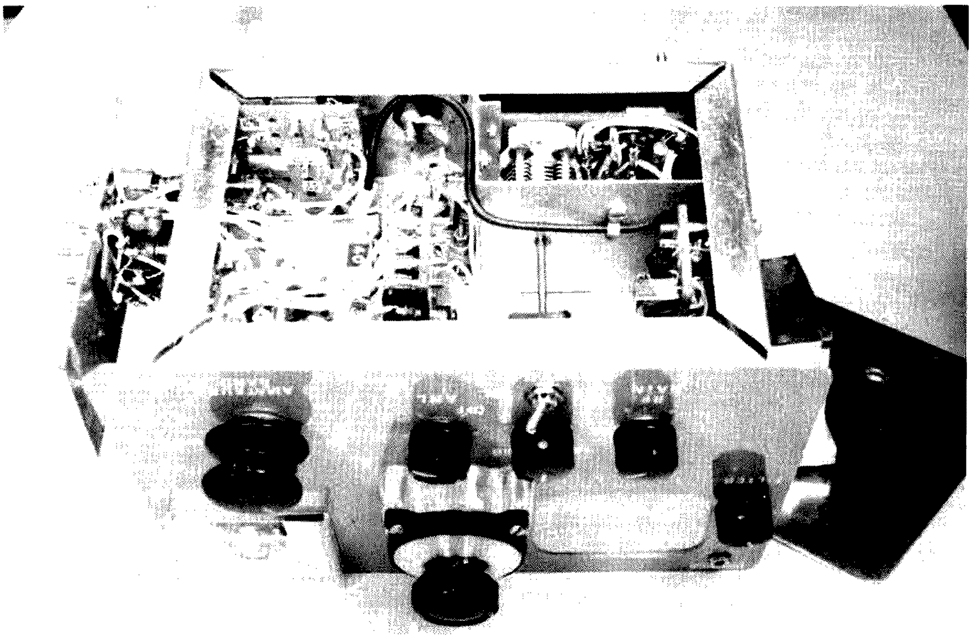

Fig. 9. Underside of chassis. Left to right: converter transformers on loosened panel, HF LO converter circuit board in back of bandswitch, LO multiplier, BFO in back of shield, 1 MHz amplifier.

tone at the speaker.

The last and simplest adjustments are made to the S-meter calibration pots, R32 and R33. Without an rf signal being applied to the receiver input, rotate R34 fully clockwise, place the BFO switch on, and adjust R33 to a position where M1 indicates zero. When an rf signal is present, M1 will deflect to a value proportional to its power. There is no clear-cut amount of rf power per S unit, so set R33 to a place where what you believe is a S9 signal in the phones reads S9 on the meter.

If you use a dial marked 1 through 100 like I did, a calibration chart will have to be made. One curve, and only one, is needed for all bands, because the BC set does the tuning each time. Fig. 6 shows how an easy-to-read chart may be laid out. The points for the curve are located by picking up the output of a 100 kHz crystal calibrator, and knowing the frequency of the converter crystals. Subtracting the HF rf frequency from it will locate the band scales on the chart.

Conclusion

This whole project was a very satisfying success. However, you could always do better if you had a second chance. The next time, I would replace the FT-243 style crystals with smaller devices, even though it would run up the cost.

Also, their frequencies would be such that the LO multiplier could be eliminated, reducing the battery drain by 5 mA. I believe that I would make the front panel larger to accommodate a different type of dial. I cannot find any fault with the semiconductor devices or the BC set, so I would stick with them.

In fact, the whole receiver fits and works so well beside my keyer that I am in no hurry to change anything. ■

Ham Help

Many people express an interest in ham radio, but find it difficult to locate a ham to answer their questions, peak their curiosity, and enroll them in a local area class. As public pressure for our frequencies increase, we must increase both our public awareness and our numbers in order to survive and grow. Through a new program called Ham Help, we hope to be the link between the prospective ham and you, the local radio club, the neighborhood ham, and the nearby radio class. Here's how it works.

A prospective ham will call the Ham Help number, ILL-1676. The 24 hour line will be answered by John Russell WB9UEC, Ham Help Chairman, or an answering machine. After getting the name, address, and phone number of the prospective ham, John will call a volunteer ham in the prospect's neighborhood. The volunteer will, in turn, call the prospect, and, hopefully, take a personal interest in the newcomer.

A program like this will obviously only succeed if all area clubs will volunteer information on area classes and keep the Ham Help file current. Here is what your radio club can do to help make it work:

INFORM: Call the Ham Help line to let John know about classes — include specifics such as dates, times, location, and who to contact. Please don't assume we have all the information we need; we can only get it from *you*. Continual updating of class information is essential for the program to work.

REFER: Refer others to Ham Help. We will be glad to be the clearinghouse for all classes in the area. Have them call ILL-1676 and we'll take it from there.

VOLUNTEER: We need volunteer hams to call back prospective hams that may call from your area. Invite them to your shack. Tell them about a class in your area (John will give you the info). Bringing a new ham into the fold is a rewarding experience that is good for you, your radio club, and the hobby. Call in to Ham Help and volunteer your services as an "Elmer" in your area. If your club would like to handle all requests from a certain area, let John know, and we will be glad to refer prospects to you. A good way to increase membership in your club!

Let me stress that, though CFMC is funding this program, we wish it to be a truly inter-club project. The Chicagoland area is ripe for a program of this type. Our hobby is the finest in the world — it's time we began to show it off!

Only through your club's (and its members') participation can Ham Help work. We ask that you print this in your bulletin or newsletter, and announce it at your next meeting.

We are banking on your continual support of Ham Help to make this program a huge success, and to bring new blood into our hobby and our clubs.

Rich Casey WA9LRI
President
Chicago FM Club
Arlington Heights IL

By way of background information: I am 67, still hold a lifetime FCC permit to operate on the former marine 2 to 4 meg band, hold the first renewal of my CB license (but have become disenchanted with that crowd and do not operate my Johnson 323 Messenger), have built a half dozen Heathkits (from stereos through VTVM to tachometers), and have just been nudged by a summertime neighbor, whose permanent address is Cleveland, to seriously approach ham radio. I have one of his back issues of *QST* and the July '76 issue of *73*.

Up here in the puckerbrush at Bridgton, Maine, amateur radio is practically unknown. I can't find a soul who can give me counsel.

I have written ARRL for a half dozen books (not yet received), and have ordered from Heath a starter set of code practice records and practice key toward going for Novice, or if I have enough practice time, to try for General in one jump.

From my copy of FCC Rules and Regs, Vol. VI, I have found Bangor, Maine, is the semi-annual location of examinations. How do I find out when and how much? How do I find out if there's a General in the area who could examine me for Novice?

How do I find out — in a HURRY — what licensed hams have known for a long time? Huh? Time is of the essence, because on this side of 60 there's a hell of a lot less of it remaining than there was on the front side!

From what little I know now, 80 through 10m is the spectrum that interests me, and I am looking for a used receiver, 5 band, SSB, all solid state, in perfect working order, to do a little listening, and to gather some education on the way. To get some good out of it, an antenna is a prerequisite, and some ideas on a simple dipole which I can hang between a couple of trees would be most welcome. Lightning arrestors, which are effective, are a must in this mountain country, where it gets pretty "snappy" now and again.

As you can plainly see, I'm not asking for much help, just the whole ball of wax!

Whatever assistance you may be able to provide would be most welcome. Thank you very much.

Charles A. Jurack
P.O. Box 145
Bridgton ME 04009

For those in our area needing help for Novice through Extra, please contact: Carthage Amateur Radio Society, c/o Mr. Dan Waters, Vocational Education Bldg., 6th and River Streets, Carthage MO 64836.

We meet each Wednesday evening at 7 pm local time at the vocational building.

Howard Gravitt WØCZT
Carthage MO

I really enjoyed your articles about computers in the Aug. 76 issue of *73*. I am 14 years old, and before we moved to Texas, I used to be real good at computer programming. The middle school that I used to go to had several terminals connected via telephone to the main computer at Westfield High School. The computer was a "Digital" PDP/11, BASIC language. The school I went to taught computer programming starting in grade 6. (The name of the school is South Middle School.) When we moved here, I found out that computer programming is not taught until 11th grade! If there is any way that I can use a computer near here, will you please let me know? I really enjoyed computer programming in BASIC language and would love to do it again.

Tom Trusty

Arlington TX 76013
(817)-274-7998

P.S. I am waiting for my Novice call to come back from the FCC. I took the written test about 1 month ago, and the code test a few weeks before that.

I think amateur radio is great, and I would like to add my name to your Ham Help list. I am willing to help any interested person get started in amateur radio in the Michiana area. All they have to do is drop a line to me.

Ron Lula WB9WXO
55428 Meadowview Ave.
South Bend IN 46628

We would appreciate it if you would list us in your "Ham Help" column. *73* is a lot easier to read than *QST* because it is at our level. We already have 2 receivers, but they are not very good. Thank you very much!!!!

How Do You Use ICs?

-- part IV

Alexander MacLean WA2SUT/NNN0ZVB
18 Indian Spring Trail
Denville NJ 07834

To those who are used to struggling with the vacuum tube version of the electronically regulated power supply, the IC voltage regulators can be quite an experience.

Within the realm of what is possible when working with any infernal electronic device, to know them is almost to love them.

While they come in a wide variety of sizes, shapes and internal configurations for specialized purposes, most of the jobs that the beginner and even the more advanced builder would have can be handled with only a few of the most commonly available types.

Here comes the fun part. Using these IC regulators is almost as simple as plugging in a transistor. The ones of most interest are three terminal devices and require only a few external parts.

The IC regulators are classified as linear devices. While there are a number of ratings which might apply, and a number of ways to get a more complex regulator using them, it is the simple way we want to explore.

As most of this series has been devoted to the digital ICs, the first voltage that would be of interest is the regulated five volts dc that the digital ICs require.

For this job there are two very common regulators which you will find in many of the circuits. They are the LM309H and the LM309K. (The LM109H, K are almost identical and are also commonly available.)

As can be seen from the numbers, they are very similar to each other. There are two practical differences between them: the package they are in and the power they will handle.

The LM309H is in a T0-5 transistor type package and will handle about 200 mA. The LM309K is in the T0-3 type package and will handle an Ampere of current.

Fig. 1 shows the pin configurations of the two. These are from the bottom of the package. While the DIP (Dual Inline Package) ICs are counted from the top of the device, these are from the bottom, like transistors.

This may be confusing until you get used to it, since you may be working from the top with a breadboard matrix or other construction technique.

With just three pins, you don't have a lot of choice to make. One is the voltage input, one is the regulated output and one is the ground connection. It would be hard to go wrong. Just make sure which pin is which.

Fig. 2 shows how the device hooks into the power supply circuit, and its basic external components. While the device can be used with as high as 35 volts input, there are dangers to doing this which will be explained later. Assume that the supply shown is in the nine to twelve volt range.

It is very important to understand the purpose of C2 and C3. They are not there to supply additional power supply filtering in the ordinary sense. A typical value for Cl would be in the neighborhood of 5000 uF, so the two additional capacitors with those values would have miniscule effect.

The technical data lists them as optional and not being needed for all applications, but don't you believe it. So what are they there for?

Specifically, they are there to prevent self-oscillation of the regulator IC and to prevent external pulses from upsetting internal operation. Self-oscillation?

A simple transistor regulator consists of a pass transistor to handle the current, controlled by several signal type transistors. As the voltage varies, it creates a signal which goes to the control circuitry which tells the pass transistor what to do to hold the voltage steady.

The LM309 has about 19 transistors and a heap of other parts in it. Even though there are only three pins on the outside, there is a whole lot going on inside.

As with any transistor, there is always the danger of it breaking into oscillation since it has the overall effect of being a high gain device.

This also means that it is susceptible to pulses from the outside getting in to cause trouble.

Even though this may not be a problem in all cases, the reports of IC equipment and experimentation so far have come up with another reason why they should be used as a matter of course.

ICs seem to find the signal they want in normal operation. This normal operation usually includes square waves which means there are going to be harmonics, spikes and so forth.

While ICs seem to thrive on a diet of crud and garbage like that, the rest of the world is not so tolerant. It would seem prudent to try to remove as much of it as possible from the nearby environment.

Shielding and bypassing should be employed as a matter of course to help keep this stuff from getting to the

Fig. 1. LM309H (K) 5 volt regulator.

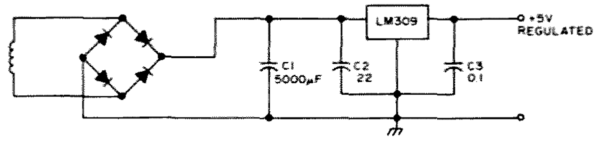

Fig. 2.

outside world.

The regulator bypass capacitors will not only help to protect it from itself and the rest of the circuit, but will help keep down the amount of damage that can be caused to other equipment from interference.

While the regulator can be located any reasonable distance from the supply, care should be taken with the placement of these capacitors.

While most of the IC parts values appear to have quite a bit of leeway, these appear to be specific values and should not be skimped on.

As with any bypass capacitor, locate them as close as possible to the regulator itself and keep the leads as short as possible.

While these two will handle the bulk of the jobs you will have to do with digital IC power supplies, there are many projects that will require a wider range of voltages.

Most of this can be handled by the LM340K or the LM340T positive voltage regulator series. Fig. 3 shows the pin configuration of the two and the chart of available output voltages.

The basic difference between the two is the package. The LM340T is in the T0-220 transistor package and the LM340K is in the T0-3 transistor package.

Either model will handle an Ampere of current output with care. Fig. 4 shows how this regulator hooks into the main circuit.

As the schematic shows, the same values are used for the bypass capacitors with this IC as with the LM309 series regulators.

The same precautions should be taken with the placement and the lead length — as close and as short leads as possible.

Fig. 5 shows the negative version of the LM340. This is the LM320T(K). Notice that there is almost the same range of voltages available. Also notice that the pin configuration is slightly different. This is important.

The negative input is also connected to the case which can then be connected to chassis ground, thus keeping chassis ground at negative potential if desired.

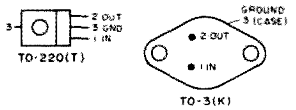
Notice in Fig. 6 that there is a ground symbol used rather than the familiar chassis ground. This is confusing as it is not the old meaning which was literally an earth ground, as opposed to the chassis common point which may or may not have also been grounded.

Here what is intended is the circuit common point, and not necessarily a connection to either the metal chassis or to an earth ground.

With solid state work there is often the problem that the circuit common connection can be either plus or minus and may not necessarily be either chassis ground or earth ground, and either plus or minus potential may be connected to the chassis or ground independently of the circuit common connection.

It makes for quite a few possible combinations which must be carefully watched for in the circuit. ICs are usually more straightforward in this

Fig. 3. LM340T(K) regulator. Code number includes voltage. LM340T (or K)-(5.0, 6.0, 8.0, 12, 15, 18 or 24).



respect than transistors.

There is one big difference in the circuit which is immediately apparent in the schematic (Fig. 6). This is the value of the bypass capacitors.

They are ten times bigger than those for the positive regulators. Also they are rather specific about the type of capacitor that is to be used. They should be solid tantalum. Those are the minimum values that should be used. They can be higher if convenient.

About now panic is starting to set in as you try and figure out where to get solid tantalum capacitors. No, you don't have to try a midnight raid on Cape Kennedy. These are a fairly common surplus item. Usually the same catalogs that have the ICs you want will also list the solid tantalum capacitors you need to go with them.

While there are applications where you might want to build a negative regulated supply by itself, most of the time working with a separate supply you have only to switch the leads to do the job. This circuit was shown to simplify a larger supply.

There is one area where you will certainly want this type of negative supply. This is when you get into working with the IC op amps or other ICs which require a dual polarity supply.

These ICs make it very simple to get your plus and minus supply. All you have to do is put a negative and a positive supply back to back and you have it made.

This is shown in Fig. 7. As can be seen, this is virtually the same circuit as the two individual supplies, but now they are both together. The only thing that has been added is two diodes.

For this type of supply you just choose two regulators with the same output voltage, whatever is desired. These two were intended for just this type of service.

The diodes are a protective device to let the regulators start up looking into a common load. They may also serve the purpose of preventing a wrong polarity voltage from getting from one regulator into the other.

Notice that they are reverse polarity to the supply each is across and would block the voltage from the other where a load resistor would not.

The diodes are rated at the regulator short circuit current rating. For 12 and 15 volt dual supply (one Amp), a 1N4720 is listed. For a 15 volt 200 mA supply, a 1N4001 is listed.

That is the overall survey of the basic type of supply you will be working with. While there are far more complex configurations to handle extreme situations, these will serve for almost anything you might want to try.

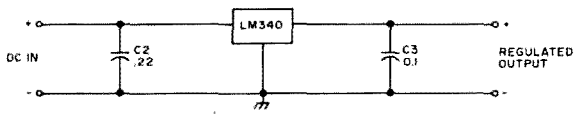


Fig. 4.

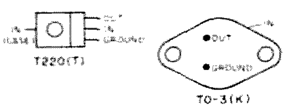

Fig. 5. LM320T(K) negative voltage regulator. LM320T(K) (5.0, 5.2, 6.0, 8.0, 12, 15, 18 or 24).

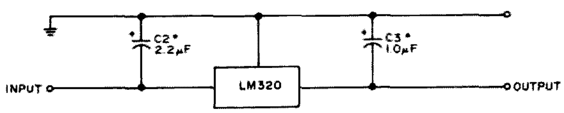

*Fig. 6. *C2, C3 — solid tantalum.*

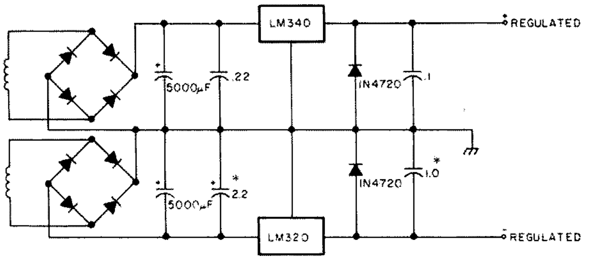

*Fig. 7. Dual polarity supply. *Solid tantalum.*

Within the range of simple variations on the basic design, you will be able to get even more practical advantage. However, before getting into variations, a few words are in order on the preservation of these devices.

While they are quite rugged when used as intended, as all transistorized equipment, they are quite intolerant of any mistakes you might make.

The easiest mistake to make is with the internal device dissipation. Most of these regulators will accept a voltage input of up to 35 volts and still give the required voltage output, but there is a built-in booby trap.

Assume that you want five volts for a digital circuit and have available a twenty-four volt supply. You could simply add the regulator circuit as shown in the drawing and you would get the five volts output, up to a point.

Under a light load, you would probably be OK, but when you started to draw much current, good-bye IC. This is the internal rating problem.

Assume that you want to draw one full Ampere of current through this regulator. With five volts out and an input of twenty-four volts, you are left with nineteen volts to deal with.

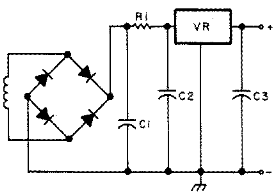

Fig. 8.

At one Ampere through the regulator, that means almost twenty Watts has to be accounted for. It helps to remember that this is a regulator, not a power resistor, and should not be used as one.

Some of these regulators can go a little over their ratings and may be more forgiving with the use of the proper heat sinks, but there comes a point where you have troubles.

Most of the regulators such as the LM309 series are built with an internal shut down feature for when the going gets hot, but even then you don't have to go asking for trouble.

There is one very simple way to deal with this particular problem. Use a dropping resistor. This is shown in Fig. 8. The value is quite easy to figure once you know what you are looking for.

Most of these regulators are designed to operate with anything from one volt over their rated output voltage up to their limit. To leave some margin, figure on a two volt margin.

In the example shown, the output is to be five volts and the input is twenty-four volts. The desired input is seven volts, two more than the device output. Assume that the maximum current of one Ampere is to be drawn.

This means that the resistor must drop seventeen volts. This works out to a seventeen Ohm resistor. If you want to be very safe, use a 20 Ohm resistor.

The power involved is seventeen Watts. Use a twenty Watt resistor at the minimum. Most of the time for experimental work you will not be drawing the full output, but it's nice to be prepared.

While this might be an extreme example, it is within the range of what might be encountered when you are working with what you have on hand. It points out your most effective rule of thumb.

If you want to have the maximum reliability of the circuitry when you are experimenting or designing, stay as far within the ratings as you possibly can.

The simplest thing to do is to start with the voltage you plan to use as the input source and then figure what the full load current and power would be through the regulator. As long as it is within the device's ratings, you would be safe.

It would be better to use the resistor as a matter of course, figuring it as in the example for two volts more than the output of the regulator.

This is based on a steady supply voltage. If the supply voltage drops under load, you may have to determine the resistor value experimentally for the correct input to the regulator. You should have some margin to work with above the two volts you are aiming for.

In this case you want to make sure that under full load you get the required input to the regulator. Under light load a higher input can be tolerated because it will not be dissipating much power.

Once you have the safety requirements for these regulators in mind and know how to work within them, there are several tough dog problems which have surprisingly simple solutions.

The first, and most obvious problem, is what to do when you need to supply more than one Ampere of current. This doesn't often come up with experimental circuits, but does with a lot of finished equipment.

The technical type answer to a problem like this would be to use an external pass transistor with the regulators as the controlling element. The transistor can handle the extra current, but it makes for a more complicated circuit.

There is an easy way out. Use more than one IC regulator. Split up the load among several so that no one has more than it can handle. This is shown in Fig. 9, and is quite a common feature of many circuits. It also provides better decoupling between different parts of the equipment.

When you are working with experimental circuits it would be nice to have a variety of voltages available. A multi-output supply is a formidable undertaking . . . or is it?

That same technique can be used to provide a number of standard output voltages. Fig. 10 shows the basic schematic. The resistance values can be figured the same way as in the example already given.

One thing to keep in mind is that the total output current is limited by the output current available from the basic supply. Thus if the supply can only handle three Amps, then you cannot draw more than that in total through the combined regula-

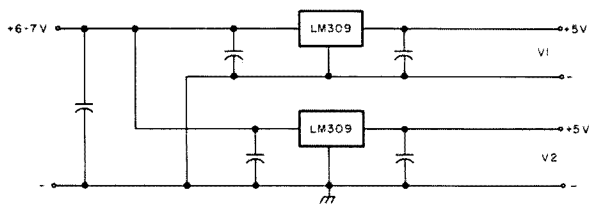

Fig. 9.

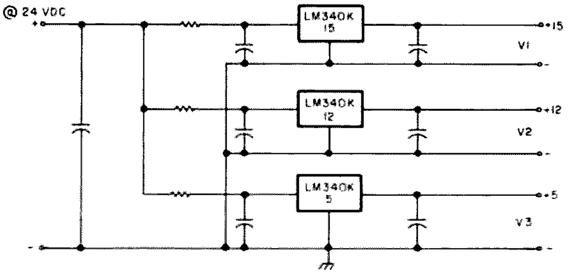

Fig. 10.

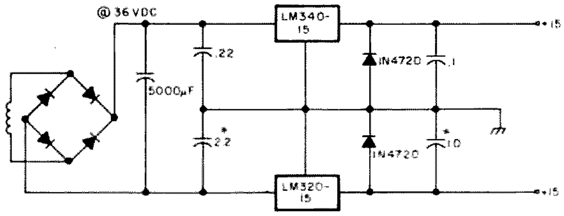

Fig. 11. *Solid tantalum.

tors.

Fig. 11 shows an oddball circuit that I was told would work with a single supply. It does not look like something for the faint of heart.

It might work, but it breaks the rules about not pushing the ratings. While normal operation would divide the voltage between the two so that each was only getting a few volts more than needed for operation, if one regulator were to short, it might throw the full voltage to the other regulator.

As this is on the dangerous side of the ratings, it might damage the other regulator too. It doesn't cost that much to play it safe.

That should handle just about any of the usual experimental or finished equipment regulated supplies you might need for most of your work.

These devices are probably the most commonly available on the surplus market, but there are many more that also can be used. Some are intended for more precise uses or other applications, but most can be used just the same way that the ones mentioned can.

A quick look shows that the external parts used are often the same values as given for the devices described.

This sort of information is usually supplied with the application notes for the IC. It would pay to get the application notes for any new type you were not already familiar with.

The IC and solid state field is constantly changing. By the time this is in print there may be a whole new line of goodies available to the experimenter on the surplus market.

There are a number of small regulators that will supply standard voltages at one or two hundred mils. These were intended for onboard use in sections of equipment and cost less than a buck each.

One item that is expensive now, but may come down, is the three terminal high current regulator capable of five Amperes of current or so.

Looking at the ads, there seem to be a number of small kits of parts and built modules that will supply sufficient voltage and current for both digital IC and op amp type ICs for a price close to what the parts would cost. They should be kept in mind as a quick and easy way into the game.

If you stick to the simple, available and cheap for a while and remember not to push the ratings, it will be hard to go wrong. ■

YOUR OWN LEXICON

May I suggest that somewhere in *73* you provide a column similar to the *QST* "Hints and Kinks" column but geared specifically to "computronics," i.e., the computer end of ham radio. Oftentimes there are little tidbits that we come across while putting together a computer system that can be of great help to others who may end up experiencing the same difficulty. Such little trivia as taking Elmer's glue and tacking each of the 48 fiber washers to the Imsai 22 slot mother board can save hours of time in trying to align each to its respective hole and also insure that there will be no shorts to chassis. Such helpful hints would not warrant a full length article and yet they are important. To further illustrate, if one wanted to purchase the IMSAI UCR1 cassette I/O board, it would be nice to know that this board is not a "connect the plugs and start recording" device. Rather, the board requires an extensive program to be entered, which takes about one hour on the keyboard and about three hours loading from the front panel. So unless one is prepared to buy an additional ROM or PROM board, there will be lots of loading to do each time it is to be used. On the other hand, the National Multiplex Corporation "CC7" data recorder will work as a stand-alone device. And, too, it will interface with current ham RTTY gear such as a model 28 or a deluxe Hal Ds-3000. We also have this recorder.

Ten months and almost $2,700 dollars later we have set up a very nice fully operating computer system. We have experienced the good and the bad. Generally the good has been Hal Communications, Godbout, etc. The bad has been in large measure due to ignorance, but also to a reluctance on the part of some companies to share with you all the pertinent information. Some companies such as Godbout and Hal will go out of their way to be helpful and specific. Others (nameless) will not do so, which puts one in a precarious position if he knows not what to ask.

Perhaps you could call the column Byte Bugs, Ins and Outs, Bug Bits or just plain Bugs. Or you could do like Shakespeare and create your own lexicon. Give it some thought, Wayne. There are a lot of fellow hams out there who are itching to jump into computronics and whose only reluctance appears to be a lack of knowledge. Certainly, one can hold the cost below that of a good transceiver and still have a fine computer controlled station that will also play Star Trek with the kids. I know, with the Hal Ds-3000 2.x tied into the company IBM-370, the IMSAI 8080 with lots of memory and a host of I/O cards and keyboards, I could provide lots of helpful hints.

Nenad S. Downing WB4SLO
Chattanooga TN

Anyone for Ins & Outs? — Wayne.

NUTS?

I've been in Taiwan, a police state incorrectly described as "an outpost of freedom," for a year. I read and speak Chinese so they don't fool me (and I've got an MA in studying them). You cannot believe how fortunate we Americans are — no secret police, no political slogans on TV, radio, and painted on every wall, a *free* press, policemen who help, not spy, and on and on and on. Of course there is no ham radio here, save for a couple of showcases in Taipei.

Add my compliments to S&D Sales. I ordered one of their cheap clocks. It arrived ten days after I mailed my order and works perfectly. Also got similar service on a CPO ordered from Heath.

Also pass on my compliments to the folks at *73*. I sent in an order for books and tapes and got them in three weeks! You folks must be nuts. Things don't work like that.

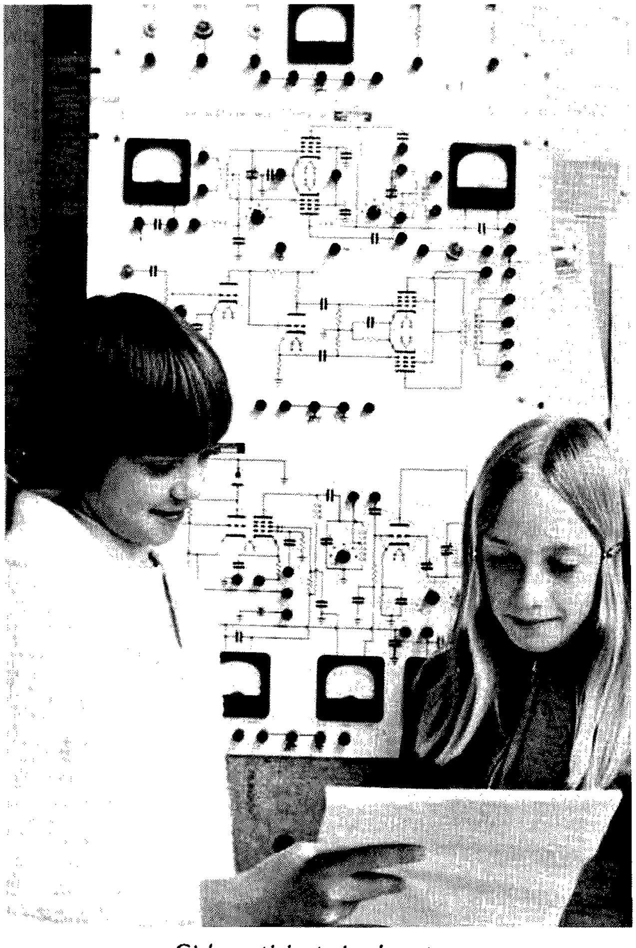
Hamming 101

-- another Cabrillo College pioneering program

Recently, I sat in on two sessions of a Cabrillo College summer school CW group. Cabrillo is a community college located in Aptos CA. The CW group is a part of ET 80AB, Special Projects in Electronics, which gives an opportunity for students to explore electronics areas of special interest on an independent study or seminar basis. Forty students are enrolled in the course; twenty-six of these are in the CW group.



Girls participate in class, too.

Eddy Pollock, Director of Technical and Vocational Education, acts as the ringmaster for this three ring circus composed of beginners, advanced, and super students. The beginners group, at present, has ten members receiving and sending at 0 to 4 wpm. The advanced group has twelve working at 6 to over 14 wpm. The super group has four members qualifying at over 16 wpm. The goal of each student is to improve his code speed at least one word per minute per week.

Eddy keeps all three groups going at the same time in adjoining rooms. A normal classroom serves as a place for instruction and code practice. Enrollees take turns on the key so that both receiving and sending practice are provided. An adjoining room houses WB6JOD, the Cabrillo amateur station. Here is where the real action takes place. All groups have a chance to get in on "live" communications at the station as well as "canned" tape programs.

No doubt some *73* readers are aware of, or have communicated with, WB6JOD or its predecessor, WA6TST. Eddy established WA6TST when he came to Cabrillo in 1960. In 1962 Cabrillo moved to its permanent and present location and was assigned the call letters WB6JOD. The station is a part of the Electronics Technology Communications Laboratory, as well as serving as the Tri-C (Cabrillo College Communications) Electronics Club station.

Mr. Pollock, a charter member of the Institute of Amateur Radio and a lifetime subscriber to *73 Magazine*, is an inspiration to past and present Cabrillo electronics students. Well over two hundred students have obtained amateur radio licenses as a result of his efforts with the Tri-C Club. The club holds practice sessions at noon during the regular school year and in the evenings during the summer. Tri-C has scored high or won several DX and Field Day contests.

WB6JOD is a busy station with many users. It operates up to 30 hours some weeks, the total time depending upon the number of personnel available for supervision. Contacts have been made with approximately 150 foreign countries and all states in this country.

Licensed personnel attached to Cabrillo include: Eddy Pollock W6KHS, First Class Radio Telephone Engineer, Amateur Extra Class, and Citizens Band; Dr. Larry Edler WB6MVK, Extra Class; Jim Marshall WA6HCL, Advanced Class; George Jurichovich K6PPZ, General Class; Royce Krilanovich K6QJZ, Advanced Class, Adult Evening Program teacher; Mary Duffield WA6KFA, General Class, Electronics for Young People teacher.

During the 1976-77 school year Cabrillo will add specific seminars for radio. ET 84AB will prepare students for an Advanced Class FCC license, and ET 84CD offers preparation for the Extra Class FCC license.

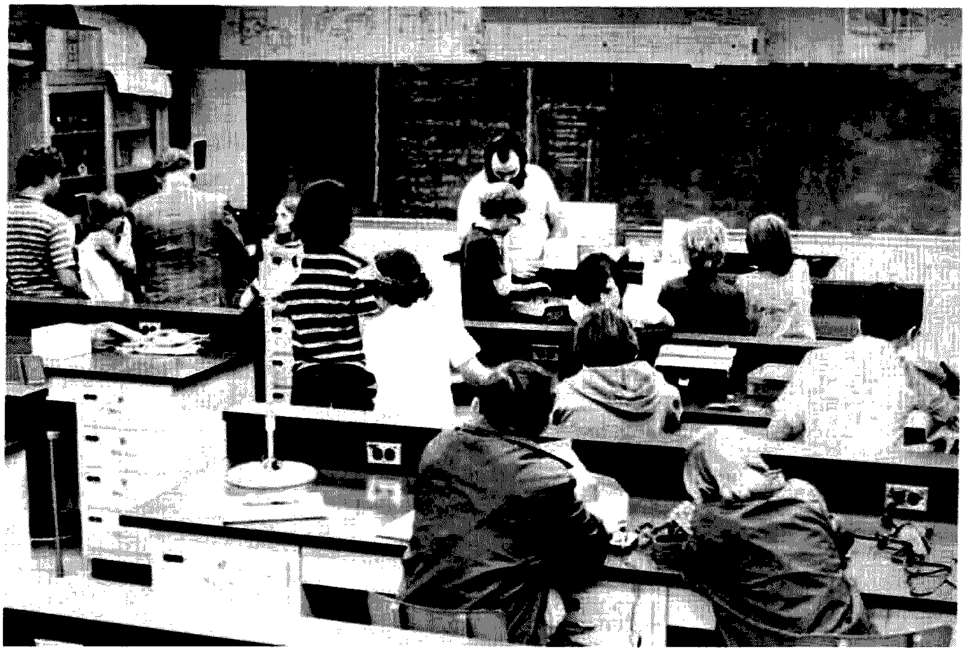
All age groups and both sexes were represented in the CW class this summer. Intense interest was highly evident in the class as members offered

constructive criticism and encouragement to each other's efforts. This attitude seems to pervade the amateur hobby groups with which I have come in contact.

Community colleges, such as Cabrillo, help to fill a vacuum that is being created in our public secondary school systems. As school financing gets more critical, special interest classes such as radio, computer programming, and other electronics courses are in trouble. As schools become more crowded, the administration begins to examine the smaller classes for possible elimination. A teacher is thus freed to take the overload. By their very nature, laboratory classes are usually small due to equipment and safety factors. Therefore, they become the prime target for elimination. New courses being suggested in the rapidly expanding computer field are failing to get off the ground for the same reasons.

Many of us in the education field feel that these classes are important – even more important than some of the traditional classes which are "required" courses for all students. We must find ways to provide this kind of knowledge to our young people. It is in this area that community services offered by such community colleges as Cabrillo prove so valuable.

Another aspect of Cabrillo's Community Services was opened to me recently. My 12 year old son participated this past year in two electronics courses offered to youngsters. One striking feature observed was the creation of a soft-sell technique for education. Public school teachers, as well as parents, could learn something from this approach. No pressure for grades and no fact-memorization to pass tests were evident. Each session was a fun-filled and information-packed experience. From the surprise gift package of electronic components, which opened



Class members of "Young People's Seminar in Electronic Projects" at work.

the first meeting, to the drawing for electronics books, which closed the final meeting, the course provided something for every participant.

This first course entitled "Electronics for Young People" was limited to 10-14 year olds. While the instructor introduced electronics fundamentals, the students were able to examine, feel and ask questions about the components under discussion. Color codes, component units, values, etc., were tied into the physical components in a meaningful way. A code oscillator, a frequency counter, a two meter transceiver and other electronic "goodies" received lots of attention during the break of the three hour sessions.

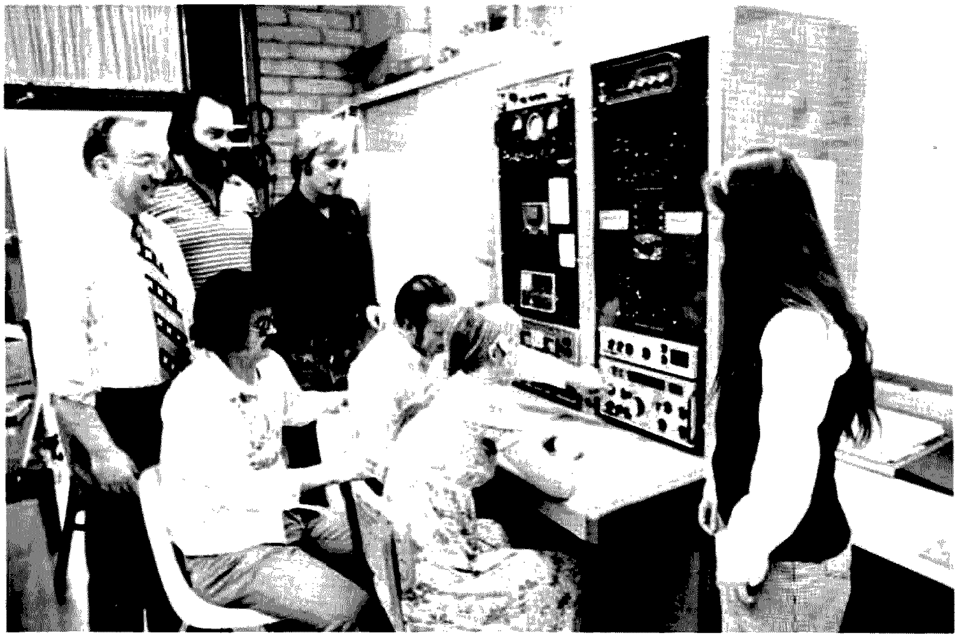
During the second session of this course, my son and I contributed a computer demonstration. An Altair 8800 with 1K of memory, operating in machine language, was used. This equipment is part of a system being built up by the Mountain Digital Group, a small local organization dedicated to providing the schools with an introduction to computers and computer programming.

While a brief description of the computer's operation was being given, Kurt programmed the computer. He loaded a few number guessing games for the students to play. (For those of you with new computer equipment but no input/output devices – take heart. There are a number of interesting things you can do through the front panel switches with only a small amount of memory.) In Kurt's first number guessing game, a correct guess triggered a music program and "Daisy" was played over a nearby radio. A guess too high turned on all the data lights, and a guess too low turned off all the data lights. The kids really went for this game. There were many "Far out!", "How neat", and "Ah" and "Oh" remarks from the young audience.

A visit to Cabrillo's amateur radio station highlighted the final meeting of the class. On one wall was a world map with a pin for each foreign contact made by the station. QSL cards were posted alongside from many stations. Eddy Pollock fired up the transmitter, and each student was allowed to speak into the "live" mike. It was several minutes before each student had sent the sounds of his voice over the airwaves. Eddy then spoke a few words into the microphone, and suddenly the students were confronted by the sound of their own voices coming back over the receiver. It seemed that Eddy's father, Earle WA6OSQ, another ham, had recorded the students' transmission and was now playing it back from his own transmitter. The students also visited the Radio and TV Lab of the college during this session.

During class breaks and at other times, Mary Duffield WA6KFA, the instructor of "Electronics for Young People," tuned in her transceiver to one of the amateur bands. While students gathered around, Mary explained how to get a ham license and encouraged all to take a crack at it.

Mary recently retired from 33 years in the public schools. Owner of a 35 foot sailing vessel, Mary was drawn to the field of radio communications out of necessity. Cabrillo provided her with the opportunity to learn electronics, and she now holds a General Class license. She has become so enthused over amateur radio that she is now thoroughly involved in



Members of Tri-C Electronics Club at the Novice station.

passing along her new-found knowledge to youngsters. As I write this, Mary is out at sea with a group of young people. They are involved in UNESCO work, contacting other young people from other countries. They're making friends via radio communications and face-to-face contact. Her summer experience should be a story unto itself.

Eddy Pollock is the real mover behind these courses for youngsters. He set up and taught the original course in 1971 at the urging of Community Services. Twelve students showed up for the original offering, and classes have been full ever since. Over four hundred children have poured through Cabrillo's doors to take part in this one course.

A natural follow-up to this introductory class was one called "Electronic Construction" taught by Eddy himself. This class opens with a quick review of the previous course. The students were then given a handful of components and a printed circuit board in order to learn and practice soldering techniques. Enough college students, who volunteered as lab assistants, were provided for almost a one-to-one ratio of supervisors to students. Recognition of components, their characteristics, and methods of mounting on printed circuit boards were demonstrated and practiced. Correct usage of hand tools, with particular stress on safety, was brought into play.

Students were allowed to select their projects from a suggested list for group purchase or to select one of their own choosing from some other source. Quite a variety of projects were chosen, including code oscillators, battery checkers, walkie-talkie AM radios, three-band radios, strobe lights, a parabolic microphone, and an infrared burglar alarm.

At the second session, all kits had arrived. An air of anxious anticipation filled the room. Before construction began, the students checked their parts lists for any omissions or incorrect parts. They were then on their own to construct their kits from the assembly manuals furnished. There was much excitement evident as boxes and plastic bags full of components were opened and examined.

"Is this a capacitor?"

"What is this?"

"Look at your parts list."

"Which resistor is the 1k?"

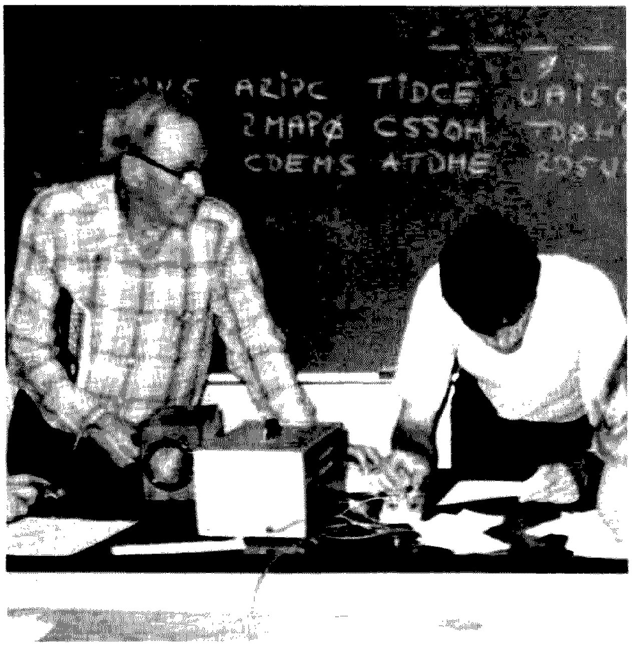
"Look at your color code."

Questions flew faster than the assistants could respond, at first. What an ideal learning environment! Then the class settled down to a semi-quiet concentration as parts began to be put into their proper places.

Two class meetings were largely devoted to actual construction of the projects. Lab assistants provided advice and aid when troublesome areas were encountered. Test instruments were provided to check out the projects at various stages of completion. Happiness and satisfaction glowed in the young faces as projects checked as desired. If the results were not satisfactory, a grim determination to find the cause and set things right was seen.

At the fourth, and final, meeting, the students were allowed some time to put final touches to their project. The projects were then arranged in groups, according to the age of the builders. Each student then inspected each project and cast a vote for the best constructed project in each age group. Students voted for the best overall project, also. Each winner received a prize, either an amateur radio book or a project construction book. The grand prize winner received a walkie-talkie construction project as well.

The future of amateur radio and other hobby groups seems secure as long as people like Mary Duffield and Eddy



Code practice even during break at 1976 summer Special Projects class at Cabrillo.

Pollock can be found. But, they need help. Look around your own community and see if such courses exist. If not, find out if facilities and personnel to start such courses can be found. Find the persons who are putting their hearts, as well as their energies, into providing for those children whose education is rapidly approaching a "no frills" condition. Give them some of your time and help if you can.

At the present time, most schools feel that they have neither the facilities nor the personnel to handle programs of this nature. They also have problems scheduling nontraditional courses in an overcrowded situation. It is my contention that provision should and must be made. Certain techniques of learning in a laboratory environment are vastly superior to the lecture-test methods of many traditional classrooms.

My particular field of interest is in computers, and I feel very disturbed in meeting strong resistance to the implementation of courses in this important and fast growing field. As a member of the Mountain Digital Group, it has been my privilege to present demonstrations in our local intermediate and high schools, as well as at Cabrillo College. We also presented a session at the California State Science Teachers Convention in an effort to interest teachers in computer kitbuilding classes. With the appearance of inexpensive kits spreading at a rapid pace, it is obvious that there is no reason a student should be denied access to a computer.

Projects carried out this past year in my own classroom have shown that high school students, with little electronics experience, are capable of putting together microprocessor kits. In addition, they acquire an amazing amount of electronic knowledge in an enjoyable, informal atmosphere. ■

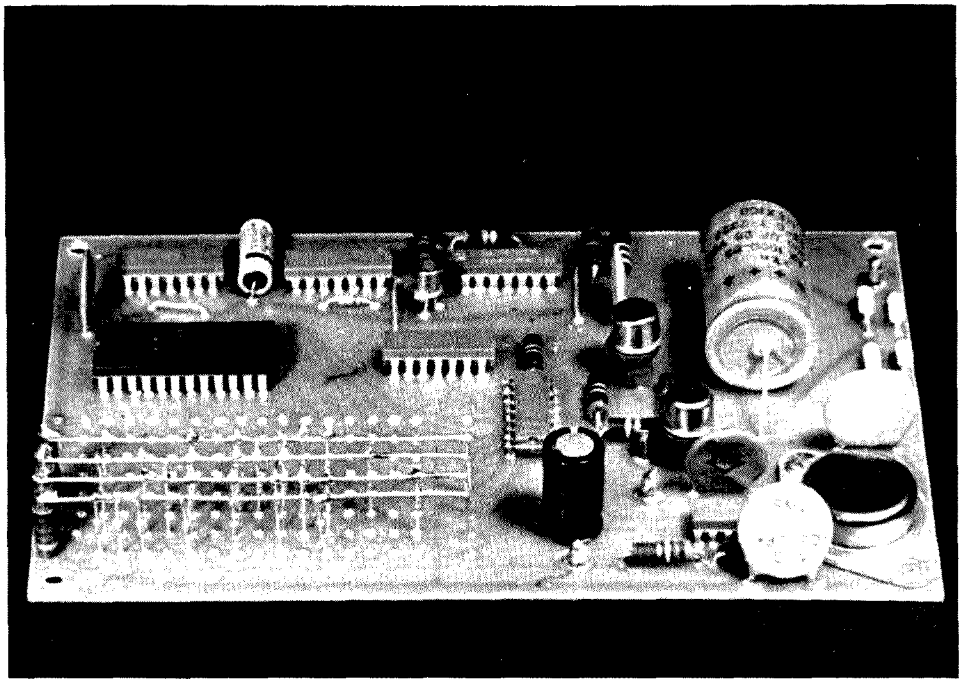
Fig. 1. Block diagram of CW IDer.

A Super Cheapo CW IDer

-- for FM repeaters and RTTY



Side view of board showing construction of matrix.

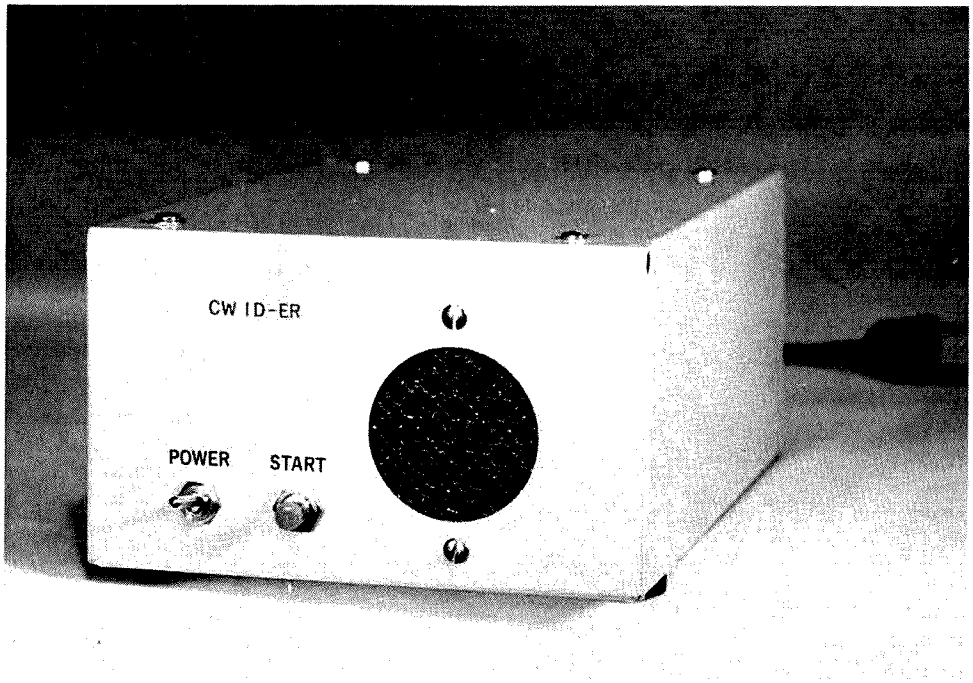
This device automatically generates your call letters for the FCC required CW identification and can be started by either a push-button or a pulse from other equipment. If you have been hand sending CW or using a mechanical code wheel on RTTY, here is a way to improve operation at low cost. It also has an audio output that can be used as a monitor or to modulate FM repeaters.

The IDer is complete on a small 4" x 6" circuit board with built-in power supply, provision for either positive or negative voltage keying without relays, monitor, and an adequate 128-bit diode memory. Its simple design is its best feature because the TTL logic required is cheap and available. The diode memory is easily programmed or, if necessary, changed when needed. Contrast this with more sophisticated designs using programmable ROMs which must be programmed correctly the first time with no mistakes. The code speed is derived from the ac line for a fixed 18 wpm. This eliminates a few parts, and adjustment, but fully complies with regulation 97.87(h). Last, but equally important, a circuit board is available to help you in construction.

Circuit

The block diagram (Fig. 1) shows the functions of the integrated circuits. U1 is a start/stop control and resets U2, U3 and U5 so they start each sequence from the same point. A push-button or pulse sets U1, the control line goes low, and U2 starts dividing 60 Hz pulses by four, driving U3. The BCD output of U3 determines the status of U4, a four line to sixteen line decoder/multiplexer – actually a sort of single pole, 16 position rotary switch. As U3 counts, U4 advances and grounds each of the sixteen outputs in sequence. In the meantime, U5 is counting each time U4 finishes a complete sweep, and with U6 is used to select the eight output lines A through H, so that only one is active for each sweep of U4. This multiplies the 16 position output of U4 by a factor of eight, giving a matrix with a 128 position or "bit" capacity. When U6 has completed its sequence, U5 generates a pulse which automatically resets U1, and concludes the transmission.

The eight input lines to U6 are pulled to a logic one by 2200 Ohm resistors mounted vertically on the circuit board. The inverted output of U6 then remains low and the keying transistors are inactive unless the scanning sequence is started and reaches points in the matrix where diodes are connected. They allow U4 to ground inputs of U6 without short-circuiting all the connections together. If we assume the IDer is at rest, pin 1 of U4 is grounded, and the input line A of U6 is positive via the 2200 Ohm resistor. Since this is the at rest or starting point, no output is wanted and therefore this position has been omitted from the circuit board layout. When the button is pressed, the matrix is scanned from the resting point A0 through A1, A2, etc., to A15, then B0, B1, B2, etc., until operation concludes at H15. Viewing the trail side of the circuit board, it is in reverse to the way you read a paragraph in a magazine. The schematic (Fig. 2) shows an example of the IDer as programmed for "DE K4EEU."



Front view of CW IDer.

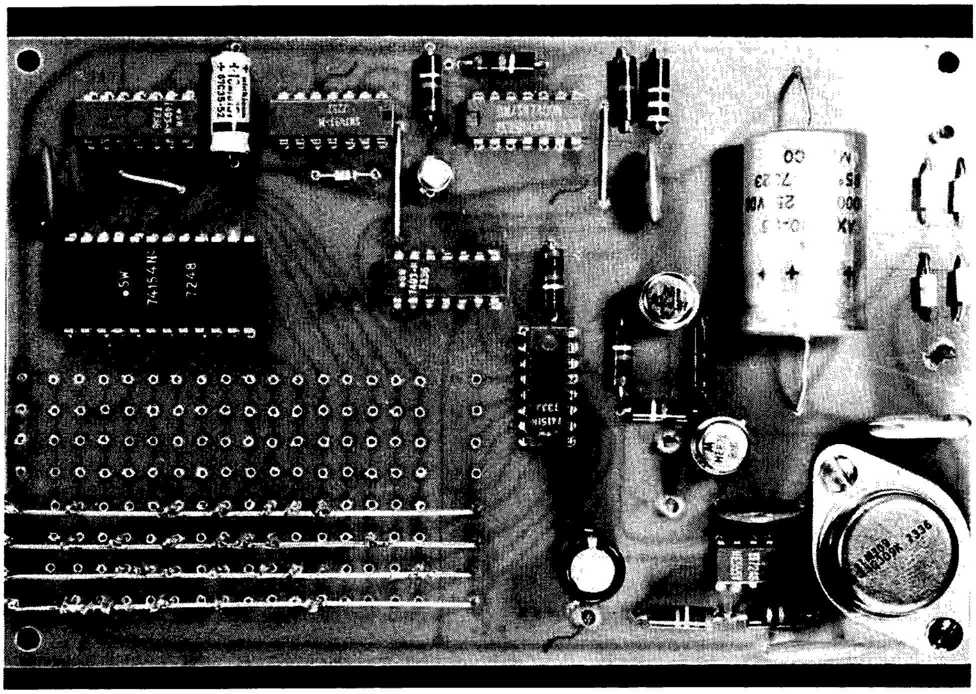
Q2 and Q3 are high voltage keying transistors. If you are keying a positive voltage, only Q2 is installed. For negative keying, add Q3 and a 1k base resistor as shown. Naturally, Q2 can be used to operate a relay if you want to key an isolated voltage in a B plus line, for example.

Monitor

The 555 timer makes a simple and effective monitor. The frequency will be about 800 Hz with components shown, a square wave which is more than adequate to drive a small speaker directly. The tone is all right for monitoring but may be cleaned up with a simple low pass filter.

Parts and Construction

A circuit board layout is given in Fig. 3 for those who want to make their own. An epoxy, undrilled, but plated circuit board with parts list is



All parts mounted on board. Note ample reserve space in diode matrix.

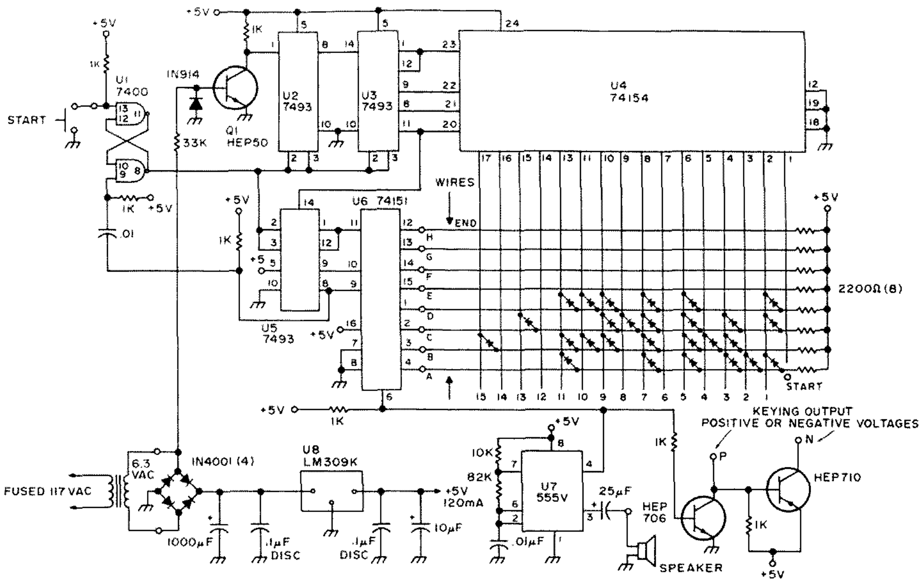


Fig. 2. Schematic of CW IDer programmed for "DE K4EEU."

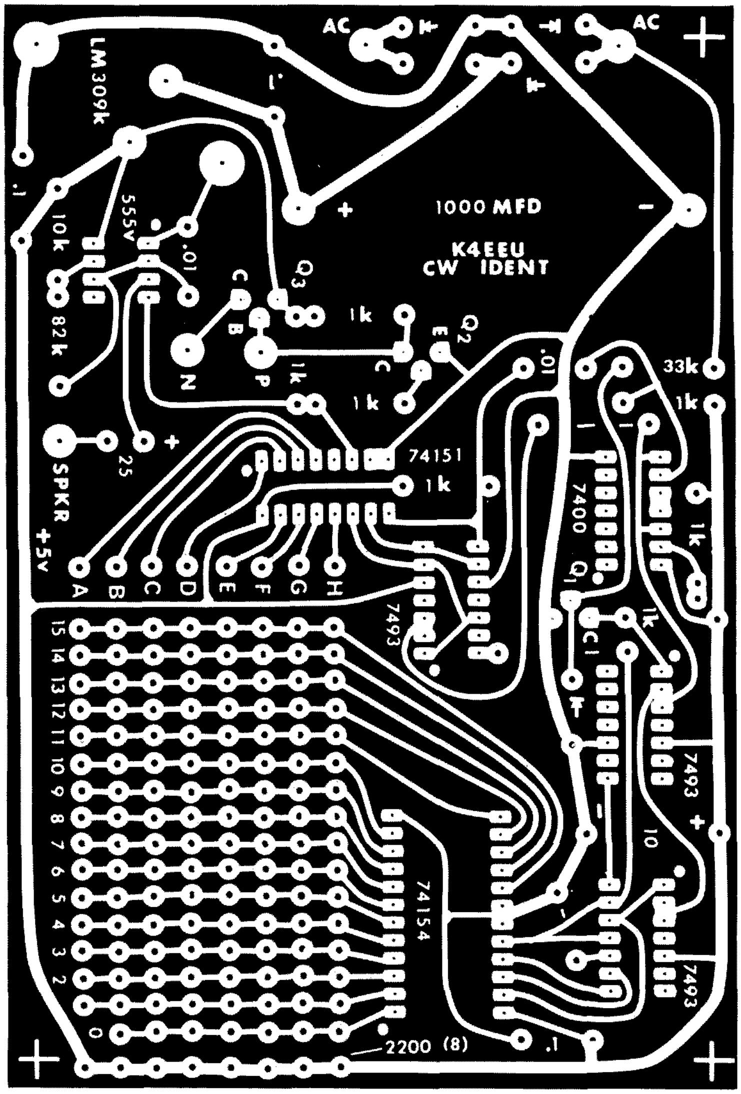

Fig. 3. PC board.

available from me for $8 postpaid US and Canada only. Parts locations are screened on the board to make construction fast and easy.

The HEP transistors are shown because they are stocked by many local parts houses as universal replacements. RCA has a similar line and SK-3018, SK-3103, and SK-3025 may be substituted for Q1, Q2 and Q3. The remaining parts are sold by advertisers in this magazine.

Note that the mounting screws on the LM309K regulator are also circuit connections, and verify that the regulator output is 5 V within a few tenths of a volt. Diodes may be either silicon or germanium, but should be checked on an ohmmeter. They are mounted vertically with cathode band toward the circuit board.

The speaker impedance is not critical. Once the holes are drilled with a #60 drill all parts can be mounted on the circuit board and the unit bench-tested in about one hour. The completed device can be installed in a small 5" x 7" x 3" chassis or mounted in vacant space in other equipment such as a RTTY demodulator.

Programming

This is done by installing diodes at locations where a tone is wanted on the matrix according to the following rules: The first bit, A0, is reserved for standby. A dash is three bits, or three diodes in a row; a dot is one bit, or one diode; a space is one bit, or no diode. Three vacant spaces between characters, and seven bits or vacant spaces between words. An L-shaped bus is formed of stiff plated wire and connected above the board between each A, B, C, D, E, F, G, H input of U6 and supported at the other end above the board by the vertical 2200 Ohm resistor. The anodes of the vertically mounted diodes are soldered to these buses. ■

The ZF Special Antenna

-- double-D "beam"

Have you been in search of an antenna with gain, directivity which you can use on all bands, and low cost? Your prayers have just been answered, because out of VP2, ZF1 comes an antenna which will satisfy all these requirements – as three years of on-the-air tests have verified.

The antenna consists of two equal triangular loops 69'9" in overall length. Both are coupled very closely by passing the loop of the driven side through the undriven side, as shown in the diagram at B.

The support boom can be made from any type of material: wood, bamboo, aluminum, PVC tubing. Nylon fishline was used for guying.

How does it work? Fantastic! Numerous hams around the world have asked me to let them have information on the antenna. The ZLs say they hear me when they hear no other station in this area. How would a 30 over 9 from New Guinea grab you?!

On 10, 15, and 20 meters, 75 Ohm coax cable provides a good match; however, on 40 and 80 meters a transmatch is recommended.

The antenna I am presently using has 4 elements at right angles to each other, with all the vertical elements connected to the center conductor of the coax and all the horizontal portions connected to the braid. Needless to say, the results have been fantastic on all bands. ■

CT7001 Clockbuster

-- the ultimate clock/calendar (for now)

For several months, I have been toying with the idea of building a digital clock using one of the many integrated circuits that are out on the market today (see the ads in this magazine). A recent sale on the Cal-Tex CT7001 clock-on-a-chip integrated circuit was too much to resist. I quickly ordered one along with six readouts and was soon on my way to constructing a digital clock. The results of using the CT7001 have exceeded my expectations, and this article is an attempt to provide you with sufficient information to build your own.

The CT7001 has many features which may be selected according to how the various scanned inputs are connected to the digit output pins. The chip is also available in either seven segment outputs (CT7001) or BCD outputs (CT7002).

General Description

Fig. 1 is a block diagram of the integrated circuit and external connections. All that is necessary to make use of the integrated circuit is a power supply, 4 or 6 readouts, and the external switching matrix which will be described in complete detail later in the article. The integrated circuit makes use of a 60 Hz timebase frequency from the power line to count the hours, minutes and seconds. There are also provisions for battery backup should the power line fail, and the integrated circuit has its own internal oscillator to take over the 60 Hz timebase. The actual frequency is determined by the RC circuit connected to pins 25 and 26 of the integrated circuit. There are no particularly critical parts of the external circuitry with the exception that you should use an integrated circuit socket rather than soldering the IC directly into the circuit. The reason for this is that the MOS type circuit is sensitive to static electricity which could destroy some of its inputs.

The particular mode of operation is determined by connecting various digit outputs to the three scanned inputs of IN1, 2 and 3. The chip was designed so that setting any one particular counter such as the time, alarm, calendar, etc., is possible without upsetting or affecting the contents of any other counter.

Since there are so many options available with the CT7001, I have not made this a detailed construction article, but rather a description of how to apply the CT7001 and by so doing, allow you to choose the options you desire in constructing the digital clock. This way, it will be possible to tailor the external circuits according to your own individual requirements.

The integrated circuit will accommodate 4 to 6 seven segment displays as shown on the block diagram. It will direct drive luminescent anode display tubes, and the application brochure from the manufacturer states that it will direct drive common cathode LEDs. However, one word of caution is in order. It will

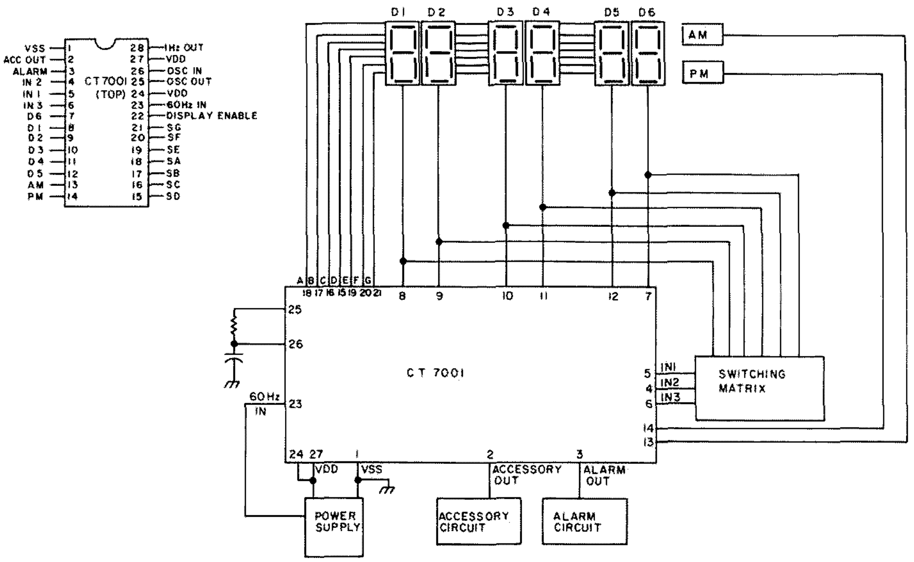

Fig. 1. Block diagram of CT7001.

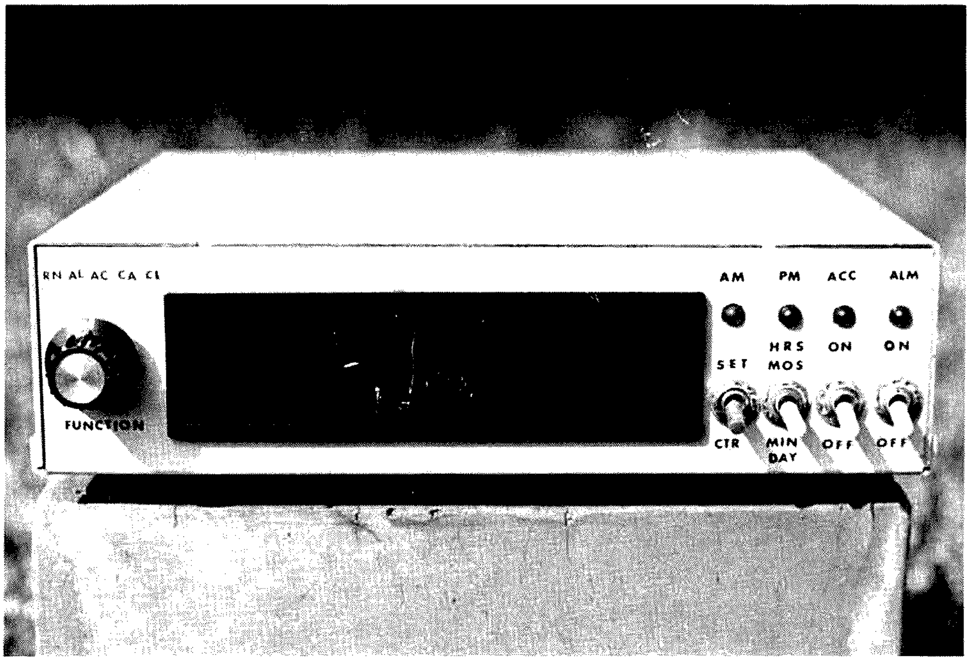
direct drive common cathode LEDs as long as the segment current does not exceed five milliamps. If your particular LED will draw more than five milliamps per segment, it will be necessary for you to incorporate either the transistor driver or integrated circuit driver that will be described later in the article.

To summarize, the CT7001 incorporates a 28/30/31 day calendar, 12/24 hour clock operation with true 24 hour alarm setting, snooze alarm, 50 or 60 Hz timebase, 6 digit direct drive display, clock radio features, on chip 60 Hz backup oscillator and easily settable counters which will be explained in the following section.



Front view.

Operational Modes and Switching Matrix

Referring to Fig. 2, we have a chart showing the scanned input options which are available with the clock. The first input is IN1 and by connecting various digit output pins to this IN1, the operational mode of the clock will be changed accordingly. Likewise, the same holds true for inputs IN2 and IN3.

For example, there are three display modes available, depending on the connection of IN3 to either D3 or D4. With no connections to the C1 or C2 inputs, the time will be displayed for eight seconds and the calendar for two seconds. If the C2 input is closed (D4 to IN3), only the calendar will be displayed on a continuous basis. Likewise, if the C1 input is closed (D3 to IN3), only the time will be displayed on a continuous basis. The am and pm outputs will operate during the clock and alarm display modes when the clock is operating on a 12 hour basis. If it is switched over to a 24 hour clock, the am and pm outputs will not be available.

This means that if the 12/24 hour input is closed (D2 to IN3), the clock will operate on a 24 hour basis (00:00:00 to 23:59:59). Should the 12/24 hour input be opened, the clock will display 12 hours with an am and pm indication both on the clock display and the alarm.

If the alarm switch is turned on (D1 to IN3), the alarm output will go high when the clock counter is coincident with the preset alarm counter. The alarm output will remain high until it is terminated by opening the alarm switch.

While the alarm is functioning, if the snooze switch is closed momentarily (D6 to IN2), the alarm will be disabled for ten minutes and this cycle can be repeated as many times as desired until the alarm is disabled by opening the alarm switch.

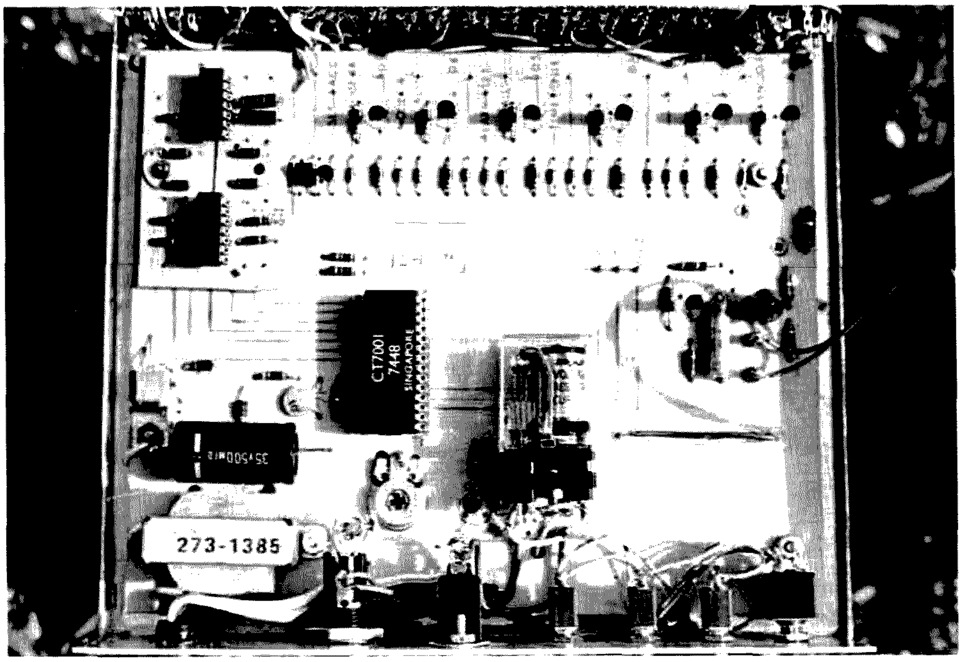
There is also a counter built into the clock chip that can be set in one minute increments from 9 hours and 59 minutes to 1 minute. This feature can be used to control some external appliance and may be utilized in three different ways depending on the setting of the Mode A and Mode B switches.

When Modes A and B are off, the accessory output will then be high for the preset time by closing the accessory switch, and this timed cycle can be interrupted at any time by opening the switch. When the accessory switch is closed again, the countdown will continue where it left off.

If Mode A is on and Mode B is off, the accessory will go high for the preset time period and also go high at the alarm time, providing the accessory switch is on. This mode may be used to turn a sleep/learning tape off automatically and then wake you up at the preset alarm time.

Input Pin	Scan Time	Input Name	Definition, Connection	Definition, No Connection
IN1	D1	Set	Set Counter	
IN1	D2	Set H/M	Set Hour or Month Digit	Set Minute or Day Digit
IN1	D3	Clock Radio Switch	Clock Radio Switch - On	Clock Radio Switch - Off
IN1	D4	Mode A	Mode A - Off	Mode A - On
IN1	D5	Mode B	Mode B - On	Mode B - Off
IN1	D6	50/60 Hz	50 Hz Input	60 Hz Input
IN2	D1	Set Calendar	Set Calendar Counter	
IN2	D2	Set Clock	Set Clock Counter	
IN2	D3	Set Alarm	Set Alarm Counter	
IN2	D5	Set Clock Radio	Set Clock Radio Counter	
IN2	D6	Snooze Switch	Snooze Switch - On	Snooze Switch - Off
IN3	D1	Alarm Switch	Alarm Switch - On	Alarm Switch - Off
IN3	D2	12/24 Hour	24-Hour Operation	12-Hour Operation
IN3	D3	C1	See note below	See note below
IN3	D4	C2	See note below	See note below

Fig. 2. Scanned Input Options. There are three display modes: (1) If the C1 and C2 inputs are left unconnected, time will be displayed for 8 seconds and the calendar displayed for 2 seconds; (2) If the C1 input is closed (C2 open), the time will be displayed on a continuous basis; (3) If the C2 input is closed (C1 open), the calendar will be displayed continuously.



The third possibility is to have both Mode A and B turned on with the accessory switch on. This will allow the accessory output to go high for the preset time *only* at the alarm time. This function may be used to turn an external appliance on for a certain length of time at any desired time. The individual counters are very easy to set with this particular integrated circuit and the procedure is as follows:

The counter to be set is selected by closing the set calendar clock alarm or accessory switch, which is accomplished by connecting either D1, D2, D3 or D5 respectively to the IN2 input. Then, if D2 is connected to IN1, the hours or month digit will be advanced. Or if D2 is not connected to IN1, the minute or day digit will be set. Once this is determined, connecting D1 to IN1 advances the digits of that particular counter at the rate of one digit per second. During the set clock function, connecting D1 to IN1 also sets the seconds to zero and freezes this particular register until the clock is started again. This allows you to set the time say one minute ahead of WWV time, wait for the tone, then switch the function switch to run at the right moment. With this feature, it's a cinch to synchronize the clock with WWV.

The calendar display for this particular integrated circuit is very unique. It has an internal memory which can determine which months have 28, 30 or 31 days. It will count the correct number of days for each month and advance to the next month at the end of the last day of the previous month. The only day which has to be manually set is February 29. This means that once the calendar is set, it will only have to be reset once every leap year on February 29. When I think of all the times I have had to manually reset the calendar on my calendar watch, this one feature is well worth the price of the chip.

Typical Circuits

Now to discuss some actual circuits you can use to build a digital clock. It is possible to incorporate either common cathode or common anode LEDs in the display. As mentioned previously, direct driving of the LED segments can only be used if the particular LED that you are using is a common cathode with a current draw of five milliamps per segment or less. Figs. 3 and 4 show a typical application for transistor driving common cathode and common anode LEDs. Six digit driver tran-

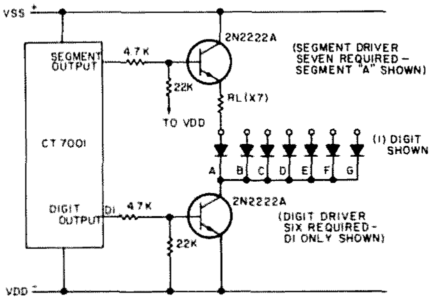


Fig. 3. LED interface for common cathode. RL is sized to limit current for specific LED used.

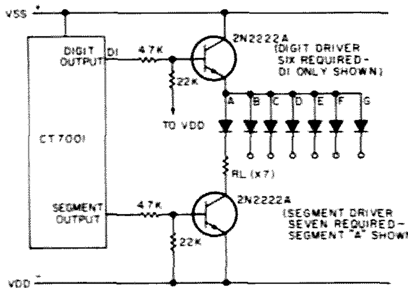

Fig. 4. LED interface for common anode. RL is sized to limit current for specific LED used.

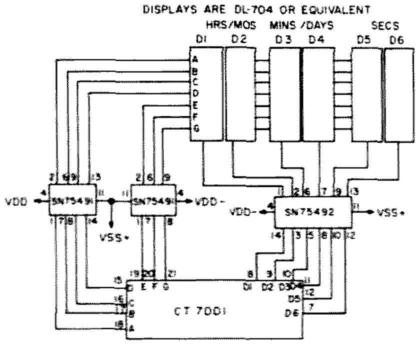

Fig. 5. Improved LED interface using SN75491 and SN75492 integrated circuits (for common cathode LED). SN75491 – quad segment driver; SN75492 – hex digit driver. Notes: (1) For both SN75491 segment drivers, pins 3, 5, 10 and 12 are connected to pin 11 through 150 Ohm ¼ W resistor. (2) Vss = 7½ to 9 V dc (10 V dc max).

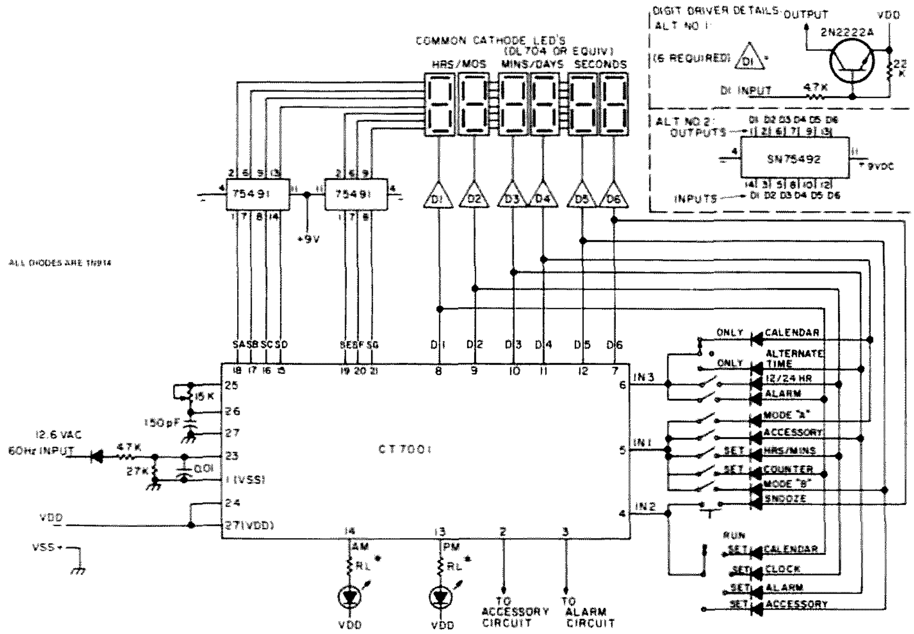

*Fig. 6. Typical clock circuit for common cathode readouts. Note: Each of the SN75491 segment drivers has pins 3, 5, 10 and 12 connected to pin 11 through a 150 Ohm ¼ W resistor. *Choose RL to limit LED current to less than 5 mA (typically 2.7k).*

sistors are required as well as seven individual segment drivers. Since the displays are multiplexed, all segments in the display are wired in parallel. This greatly reduces the number of drivers and load resistors that are required in a typical circuit.

It is also possible to use integrated circuit drivers for the digits, which greatly reduces the amount of external wiring. Fig. 5 indicates an improved LED interface using SN75491 and SN75492 integrated circuits. This diagram is for a common cathode installation. The SN75492 is a hex digit driver and the two SN75491s are quad segment drivers. For both of the SN75491 segment drivers, pins 3, 5, 10 and 12 are connected to pin 11 through a 150 Ohm, ¼ Watt resistor. The application sheet on both these integrated circuits indicated that the maximum supply voltage is ten volts and it is probably better to operate them between 7½ to 9 volts dc to avoid any damage to the integrated circuits.

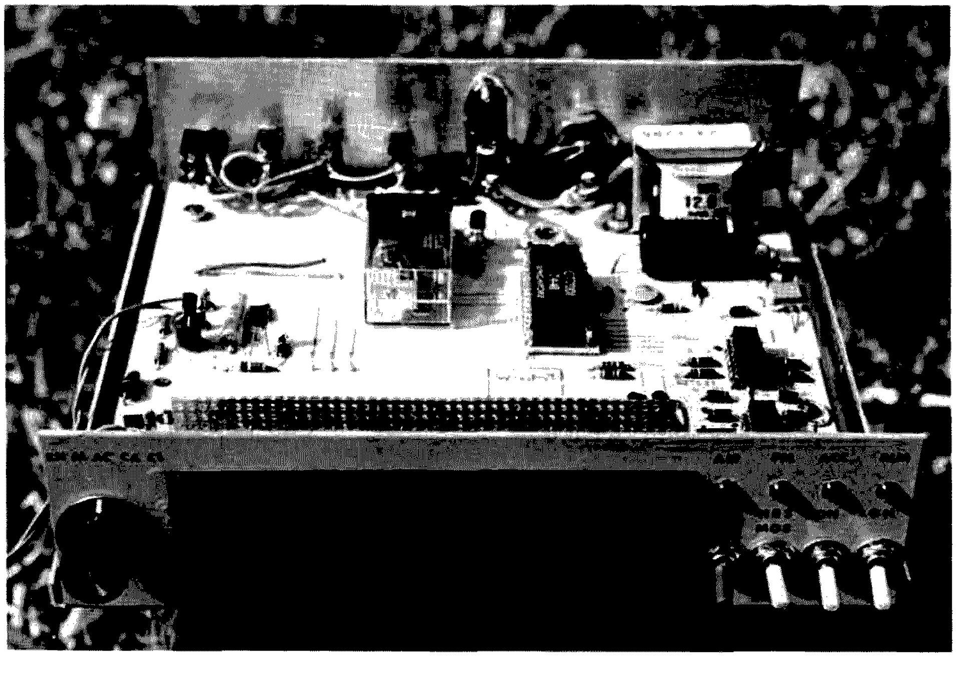
In my particular clock, I had already etched the circuit board before I realized that it would be possible to use the improved interface integrated circuits. Consequently, my particular clock is a hybrid, using six transistor digit drivers and two SN75491 quad segment drivers as a typical application. This is shown in Fig. 6 and incidentally, this diagram is a typical application which allows you to incorporate all the functions that are available within the clock integrated circuit.

In order to keep the front panel of the clock as simple as possible, I located the display select, 12/24 hour, Mode A and Mode B switches on the rear apron of the clock. The set/function switch, the set counter, and the hours/minutes selector along with the accessory and alarm switches were located on the front panel of the clock. I used LEDs of different colors to indicate the am and pm settings of the clock and also an LED for each of the accessory and alarm switches to indicate when these switches were turned on. This feature helps to remind you to turn off the alarm or accessory when you don't want to be awakened early on a Saturday morning.

There are various options in regard to the alarm circuit, and Fig. 7 shows a typical alarm circuit using a transistor driver interface to turn on a programmable unijunction transistor oscillator driving an internal 8 Ohm speaker. A potentiometer can be incorporated into the circuit to vary the tone of the alarm output to suit your own particular preference. The output from this oscillator is sufficient to awaken all but the most ardent sleeper.

A friend of mine included another unijunction in his clock to produce an alarm similar to a police siren. However, the side effects the wavering alarm tone had on his wife prompted him to quickly change the circuit back to a steady, soothing tone.

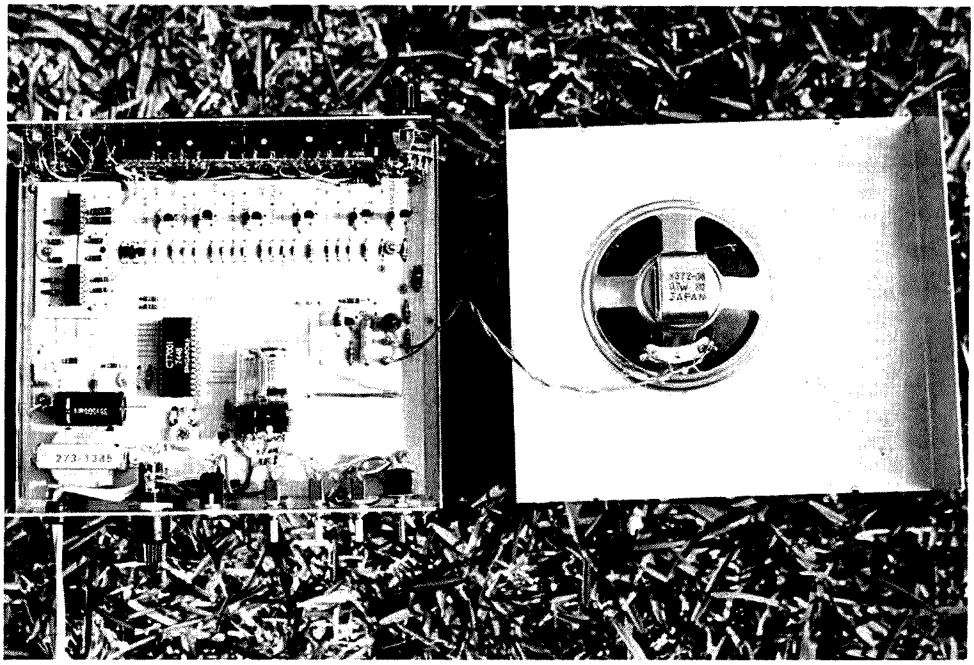
A transistor driver circuit, similar to the one used to turn on the alarm, can be used to operate a 12 volt dc relay. The contacts from this



relay can be used to control some type of accessory function such as a clock radio, lamp or appliance. In my particular installation, I am using it to switch 120 volts ac to an accessory socket at the rear of the clock which is used to turn on a small radio. However, it can also be used to turn on some external appliance or other similar function. The circuit diagram is shown in Fig. 8.

Various power supply options are available depending on your own personal requirements and the amount of regulation that is desired. Fig. 9 shows a typical power supply with a PNP power transistor used to help regulate the output for the unit. Battery backup is provided by two nine volt batteries installed with a six volt zener diode. CR2 is installed to prevent the battery from supplying power to the displays when the normal power has failed. The battery is only used to operate the integrated circuit with its on-board oscillator to keep the clock functioning during a power failure. A variation to this circuit may be used to display the time for short periods to conserve battery power. Simply connect a momentary, N.O. SPST push-button switch across CR2. This will allow you to bypass the diode to display the time.

In some cases, it may be objectionable for the leading zero to be displayed during clock operation and also during calendar display. It is possible to blank the leading zero by means of a transistor and a few resistors. Since segment F is the only segment not required to form the digits one or two, it can be used to uniquely describe zero. If segment F is present during D1 time, the 2N2222A transistor will turn off the D1 to the display while preserving the D1 signal to the input matrix. Fig. 10 is taken from a Cal-Tex applica-



Top view, showing alarm speaker.

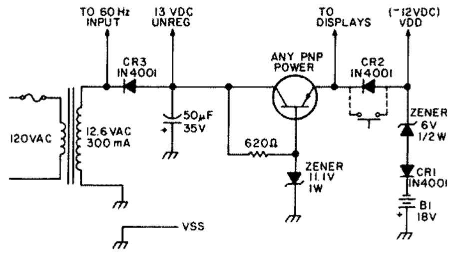


Fig. 9. Power supply for the CT7001 clock. During normal operation, all power is supplied from the ac power supply. During a power failure, the clock continues to operate from the battery backup composed of two 9 volt batteries. To limit current drain on the batteries, a diode blocks power to the displays. A push-button bypass switch across diode CR2 may be installed to momentarily view the display.

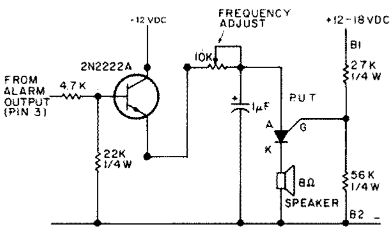

Fig. 7. PUT = programmable unijunction transistor (Radio Shack 276-119 or equivalent).

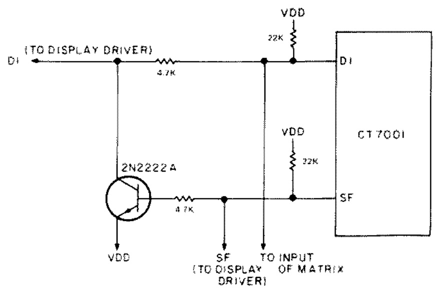

Fig. 10. Zero suppressing the D1 digit. Since segment F is the only segment not required to form digits 1 or 2, it can be used to uniquely describe 0. If segment F is present during D1 time, the 2N2222 A will turn off the D1 to the display, while preserving the D1 signal to the input matrix.

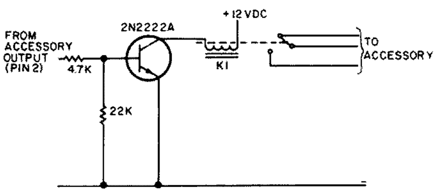

Fig. 8. K1 = 12 V dc coil relay suitable for switching accessory loads for miniature size.

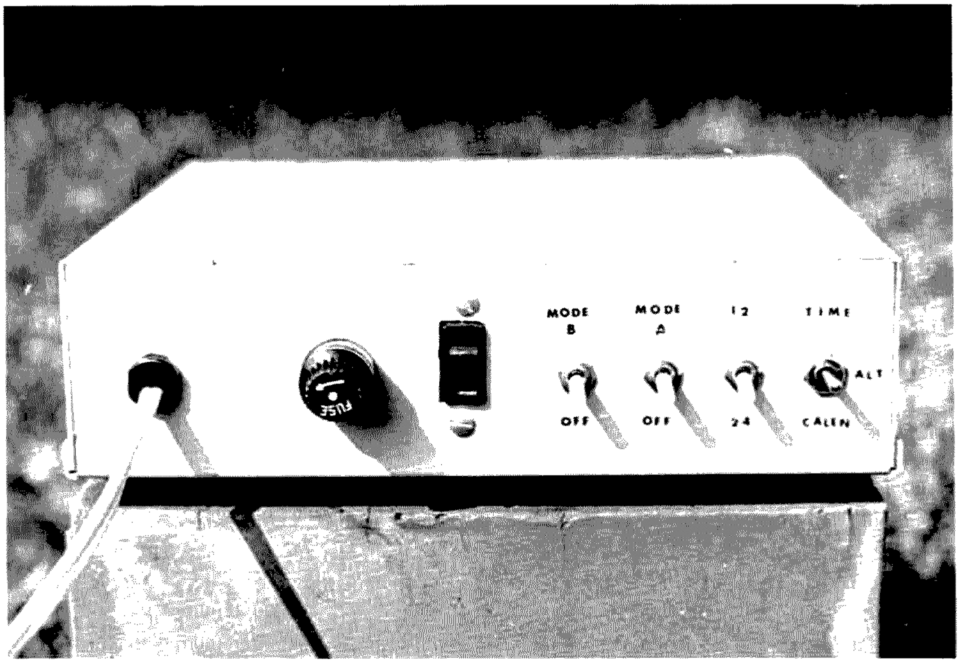

Rear view.

tion note on how the circuit should be connected to zero suppress the leading zero. Since I have not incorporated this feature in my particular clock, I can't vouch for the values of the resistors to be used, but I assume that they are the normal values that are used in the other driver transistor circuits. You might try a 4.7k resistor for the base and a 22k resistor for the bias resistor.

For those of you who desire more accuracy than the power line regulation, or for that matter, high accuracy when the power line fails, it is possible to incorporate a crystal oscillator as an external timebase. This is shown in Fig. 11 using a 100.800 kHz crystal with a one megohm resistor and a 5-50 pF variable capacitor. The frequency can be trimmed with the variable capacitor to result in a very stable external timebase whose accuracy is a function of the crystal used.

Conclusion

The clock has been in operation for several weeks now using only the timebase from the power line frequency to determine the accuracy of the clock. This timebase has proven to be adequate for most operations.

In checking its accuracy in reference to WWV time signal, I have only noticed a few seconds variation over a couple of weeks. This high accuracy is due to the fact that the power line frequency is corrected from time to time so that its average deviation cancels out. As a result, the power line is a reliable source for a 60 Hz timebase, barring momentary power lapses. When this happens, the chip displays one more feature – at the moment power is restored, the clock begins counting, but displays all 8s. This is to let you know that the count is not accurate. By momentarily closing the set counter switch, the clock display will appear. Keep this in mind the first time your clock is turned on, as all 8s is a normal indication until the set counter switch is closed.

In closing, I highly recommend the CT7001 digital clock/calendar IC, and should you decide to build your own digital clock, it's a good idea to obtain the basic application notes from Cal-Tex Semiconductor along with the supplementary application notes listed in the references. ■

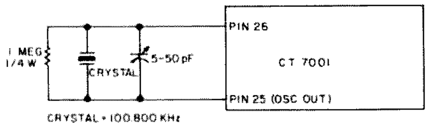

Fig. 11. External timebase. In this mode of operation, it is necessary to connect the 60 Hz input (pin 23) to Vss (Cal-Tex AN#107).

Saving a CBer

--a new resource for hams

The harsh jangling of the phone grabbed me by the eardrums, and cruelly vibrated me awake. Slowly, groggily, I fumbled at the bedside phone, resolving to leave it off the hook the next Friday night. It seemed that I had just dropped off to sleep, and a quick look at the clock confirmed that impression; it was 9 am, and I had turned the rig off only three hours ago. Trying to work Australia with my minimal antenna system was as fruitless as hunting with a water pistol – all night and no luck.

The phone had reached my ear by now, and I mumbled something into the mouthpiece. "Good morning, Karl!" said an all too awake and cheerful voice. "I just passed my Advanced exam and I wanted you to know."

"Ken, are you kidding me? You just got your General three weeks ago!" Now completely awake, I found this news to be both amazing and just a little embarrassing – this kid had done in six months what had taken me three years to do.

"Well, Karl, I had a day off from school, and I have been studying for at least two weeks now, so I decided to give it a try." He decided to give it a try, I thought; no denying that the kid had plenty on the ball.

"Well that's just great, it's fantastic, actually. I gave you your Novice not more than six months ago. Congratulations! Not many hams can beat that; not bad for a converted CBer."

He signed off and I turned over in bed, not to sleep, but to think on his brief career in ham radio, which had been nothing short of astounding. I felt more than a little satisfaction and pride. He had done the work, of course, but I had been lucky enough to provide the proper guidance and to help send him on his way.

It had started one evening, while listening on the Chicken Band (our local nickname for CB). Amid the usual strange chit chat and madeup calls, something had aroused my interest. There, he was back again. "Yes, Little Chicken, and Red Hen, this is KBC 1234 (I can't remember the exact call). I was just saying that CB is OK for some things, but everything I've heard about ham radio makes me think that it's a lot more fun, and interesting too." I couldn't agree more, I thought; let's hear more. "All the things I've heard about it sound real neat, like talking to other countries, using Morse code – I still remember that from the Scouts – and even building or fixing your own gear. You can use hundreds of Watts and not worry about the FCC. It sounds like a great hobby, but it's hard to get started. I sure wish I had someone to help me out. It's like the difference between flying a kite and flying an airplane." Not a bad analysis, and he was right. CB does have its worthwhile uses, if the legitimate stations can get out from under the cacaphony of QRM from all those "Little Chickens" on the band.

I broke in, using W5EWF's CB call and rig (which I had been testing), and asked him to drop over to my shack that afternoon, to get that help he was looking for. Expressing surprise and thanks, the young man said his name was Ken and that he lived just around the corner from my house. That was my first and last CB contact, for that rig was sold the next day, W5EWF having despaired of the way the band had developed since its early days. That one contact made for a happy result, however: the addition of a bright, talented and very enthusiastic new ham to our fraternity.

Ken was right on time for our first meeting, and I quizzed him on his background, so I would know where to start. As it turned out, he had a good start, having retained all of his Boy Scout Morse code (at a speed of about two words a minute), and having studied basic electronics in high school. All he needed was exposure to actual ham radio, as well as guidance in his studies. He went off clutching copies of "How To Become A Radio Amateur" and "The Radio Amateur's License Manual," not to mention several copies of *73*. An hour of twenty meter phone seasoned with the forty meter Novice band had whetted his appetite.

Before I knew it, I was giving Ken his Novice test. Naturally, he was nervous, and he wrote hunched over the forms, in intense concentration. After it was over, I could not help but notice that the answers (which I had accidentally seen) were all correct. Although I reassured him, Ken was anxiously waiting for the mailman for the next month or so, calling me up every other day (after three weeks had gone by), wondering if such a long delay was normal.

Then one day, Ken came running up as I shoveled snow in my driveway. Giving the last shovelful a heave, I straightened up and greeted him.

"I made it!" he shouted. "I'm a Novice, I'm a ham!"

"That's great, Ken – but I knew you'd make it. What's your call?" I wondered how far down the list they had gotten.

"I'm WN9QDL!"

"Well, WN9QDL, why don't you hustle on over to your QRP Heath rig and I'll work you." Snow shoveling really never excited me that much anyway, I thought, as I headed for the shack.

One thing led to another, and one day about mid-April, the new Novice became a new Technician, and then (after borrowing some of my code tapes and a little technical advice on theory and its practical application), guess who was a General? I was only a little bit surprised at that, for Ken had been working hard. We put up some improved antennas and I loaned him my rig so he could try phone for a while, and got almost daily landline reports on how he was doing. It seemed to me that the thrill of being off the limited Novice bands would kind of slow down the climb up through the license grades, while he concentrated on making lots of contacts. Well, I was sure wrong on that score. His radio library had been steadily expanding to the point that I was sometimes borrowing books from him, and they were all well used when I received them – he had been studying.

So now Ken was an Advanced class ham. As I got dressed, I counted the months since he had received his first call – six months, to the day. Perhaps there were more good potential hams marking time on CB; a little encouragement might be all that would be needed to find them and bring them into the hobby. I resolved to listen in on 27 MHz some more. Just then, the telephone rang again, interrupting my thoughts. It was Ken again, asking to borrow my 21 wpm *73* code practice tape; he said he's just started working on his amateur Extra and his records only go to 18. Hmmm, I wonder if he can help me with my code – maybe I'll get that Extra class myself!■

by Wayne Green W2NSD/1

I/O EDITORIAL

ATLANTIC CITY!

The Trenton computerfest last spring was such a remarkable success that another computer convention in the same general area was organized . . . this time by a group of three hams . . . and in Atlantic City for the end of August. They named it Personal Computing '76.

PC-76 was a success by any measure. There were over 75 exhibitors and over 3000 attendees (at $5 to $7.50 per head). Judging from a show of hands at my talk (the room was jammed full and several hundred were turned away at the door), and from the number of people who came to the *73 Magazine/Kilobyte* booth, about one third of those present were hams. Since the computer hobby is duck soup for hams to get into, I suppose I shouldn't be all that surprised.

This was the first public announcement of the coming of *Kilobyte Magazine*, and I was most gratified by the enthusiasm. A very simple explanation of the need for *Kilobyte* was that I wanted a computer hobby magazine that *I* could understand. An awful lot of people agreed with me and signed up for subscriptions to *Kilobyte* . . . about three times what we've ever done with *73* at any ham convention! More surprising was that 75% of them signed up for three year subscriptions . . . and the first issue won't be out until December.

MITS was there with their latest equipment set up and running. A few of the firms didn't show up . . . Imsai let their dealers do the showing . . . Sphere had one dealer there with a unit. Quite a few new manufacturers of small computer systems showed up and won converts to their hardware. It was an exciting convention.

I got into my usual troubles. A few days before the convention I got a request from the group running it to tape the technical sessions. There were going to be as many as five going simultaneously and they couldn't handle it. Hmm . . . I'd have to get some more cassette recorders and have at least five people there to make tapes . . . plus a couple more to sell subscriptions at the booth. It would be expensive, but it would be good PR. A man in the booth would probably be able to sell an average of $600 per hour in subscriptions, and Big Bill Edwards, our advertising manager, sells about $20,000 per hour in advertising during a show like that.

The idea was for us to tape the talks and then make copies to be given to computer clubs for use during meetings . . . and to sell additional copies of the tapes at $4, which wouldn't really pay for the effort, but would help take some of the sting out.

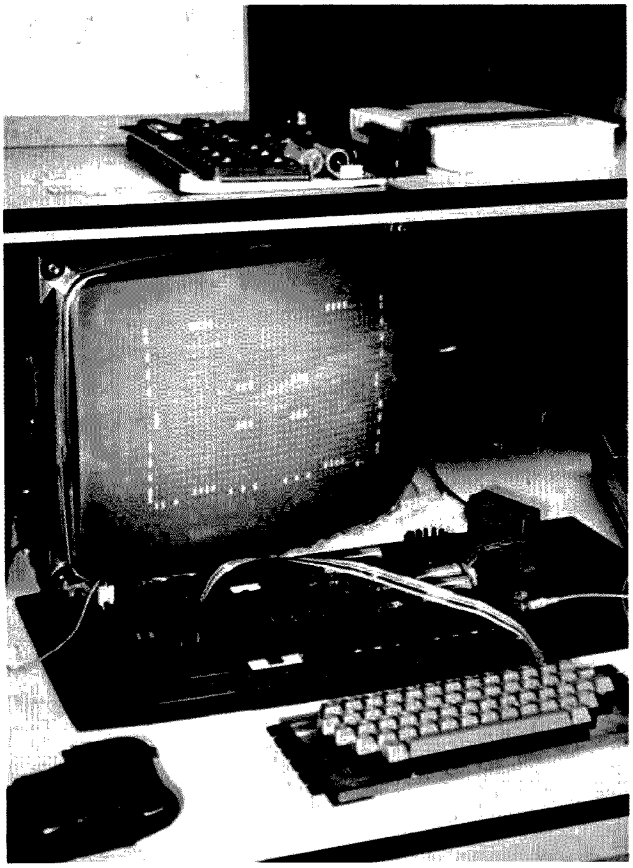
All went well for the first three hours . . . then came the word . . . no more taping. I gather that one of the computer hobby magazines made a big complaint about it and all of the money that *73* and *Kilobyte* would make out of the deal. I was angry . . . and delighted. A lot of people and clubs would miss first rate talks as a result of the politics, and that was irritating. I was glad because it saved us an awful lot of work and expense . . . probably for little return of any kind.

It was a pity, since *73* is so well set up to handle this type of thing. The tough part is having enough people to make the tapes . . . and then editing them down a bit to fit a one hour cassette . . . from there on it is easy . . . except for the sales or distribution. This means letters to clubs, handling orders, keeping records. And the sales of cassettes means writing ads, having them set in type and published (a page ad in *73* is not cheap . . . over $1000 these days), so anything advertised *has* to sell and sell well.

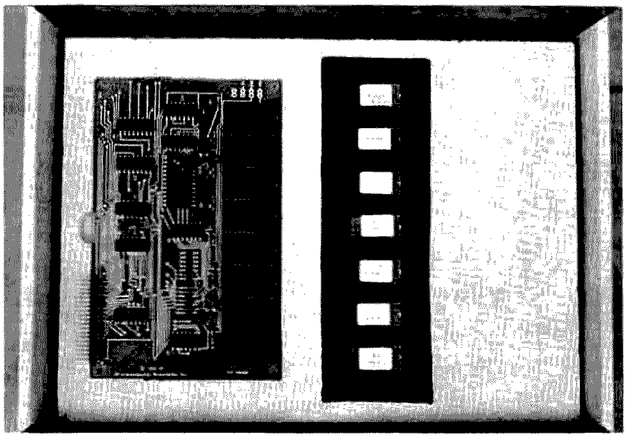
Last year at Dayton I tried to set it up so that we could tape the more interesting talks, only to have an RTTYer put in a very loud protest at "commercialism" . . . he would tape for *free*. As far as I know he taped one lousy talk and very few people ever got a copy of it – while thousands of ham clubs were prevented by him from having very interesting material for meetings . . . and the Dayton Hamvention missed out on a way to get fantastic publicity both via the audiences of thousands of clubs and via ads for the tapes in *73*.

A lot of people go to conventions in order to hear the talks, and a lot more would if they were exposed to more. And one of the most frustrating things at a convention is to have two sessions going on at the same time, neither of which can you bear to miss! I noticed that the Boston convention had their talks taped by a commercial outfit and the tapes were being made available for considerably more than *73* would charge. I do think the idea is a good one, but the cost should be kept down to ham levels and not just be a way for some commercial outfit to make a big killing.

Outside of the taping brouhaha, the incredibly miserable hotel, the

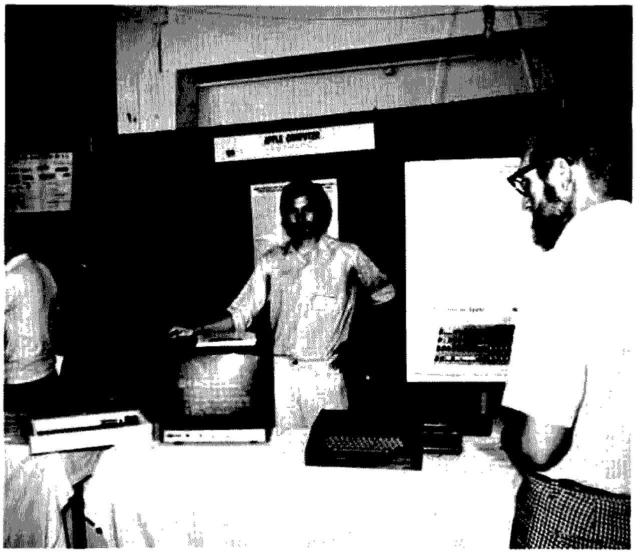


Here's the Apple computer system up and running a game of Life. Note the tiny cassette I/O board at the right! This is a complete computer and video generator, all on one board. Any wonder there was a lot of interest in this system at PC-76?



The Jolt 2K PROM board is shipped in a plastic foam package inside a carton, complete with detailed instructions. The PROMs are shipped mounted on conducting foam, to be plugged in after receipt. Jolt sells their boards in kit form or assembled. Their 1K assembler is supplied on four PROMs . . . not a bad deal for under $100 including PROMs.

Jimmy Chiang checks out Sphere boards after final assembly and debugs them.



This is Steve Jobs, the president of Apple and the chap who designed the system. How many twenty year old computer designers do you know with their own manufacturing firms?

sauna-like atmosphere much of the time in the convention hall . . . it was a resounding success. Atlantic City is difficult to get to . . . too far from any large airport for many exhibitors (a great portion came in from California). The boardwalk and amusements were tacky, but if you have a chance to get into a penny arcade (they are 25¢ now) don't miss the computer games they have for you. You'll find yourself jumping around and screaming with delight at the tank game or the dogfight flying games. These are expensive, but worth it. We found one arcade where eight people could play at once, each driving his own tank and shooting at the other seven. The games are quite sophisticated, so be sure to give 'em a try the next time you see one.

These arcade games are just a hint of some of the goodies coming for home computer use. The new six game television toys are now on the market and are fun (under $60 some places . . . Unisonic), but they are simple compared to some of the microprocessor games that are coming. The arcade games use an F8 Fairchild microprocessor and are run by software. It won't be long before those programs are available for computer hobbyists.

I/O A WINNER

A large percentage of the hams at the Atlantic City computer convention and sauna said that the I/O articles in *73* had been their introduction to hobby computing. The fact is that aside from interesting the people already in the computer industry in going into their work as a hobby, there has been little effort so far to attract outsiders to hobby computing.

One big problem is that, other than the material in *73*, there has been practically nothing published which is understandable to the beginner. The series of articles which ran in *73* introducing newcomers to the world of computing have been gathered into a book called *Hobby Computers Are Here*. This is being sold through radio stores for $4.95 by *73 Magazine*.

The computer hobby magazines have gotten into the hands of people who are more interested in esoteric articles for professionals than in helping novices come up to speed in this difficult field. *Kilobyte Magazine* promises to help solve this impass by publishing a high percentage of articles written for the beginner . . . and further, there will be a glossary of the technical terms and buzzwords in each issue.

73 has so far withstood the temptation to try and promote the I/O section of the magazine to computer hobbyists. While this would make for better results for I/O advertisers, it might be somewhat detrimental to ham advertisers, since only about 25% of the computer hobbyists are into hamming so far. This may change. The current issue of *Computer Notes*, the official publication of MITS, has a lengthy editorial on the benefits of amateur radio for computerists . . . and president Ed Roberts is hard at work aiming at a General ticket as soon as possible. Perhaps the two fields will grow even closer together.

VISITING

During August I made a quick trip around the country to see how the hobby computer industry was doing . . . and to update myself on the similar trip I made the year before.

My first visit was to Ray Holt and the Jolt computer. This is an interesting development, and far too little has been written about it. Ray has agreed to explain some of the interesting ideas he has built into the system in an article for *Kilobyte*. I suspect that Ray would be a whole lot busier if more people understood what he has done with the Jolt.

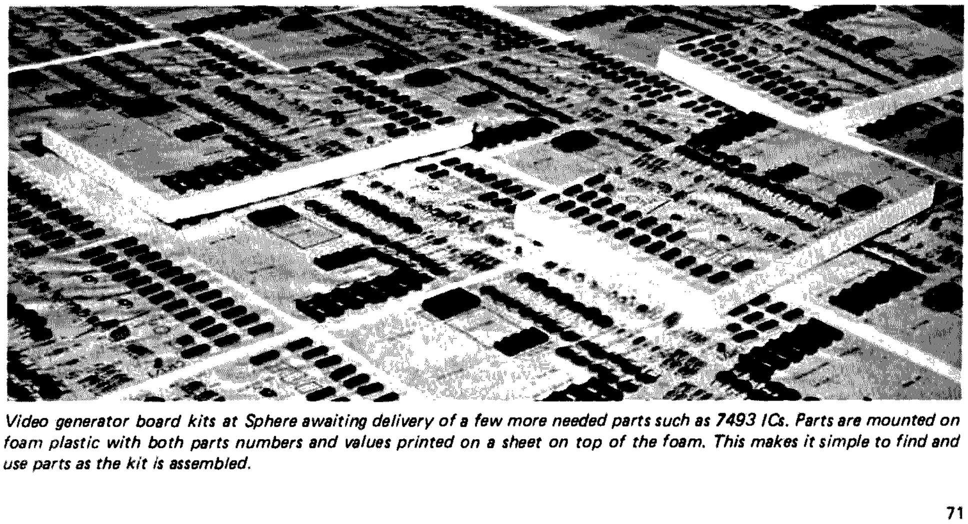
Next was a visit to Imsai. They'd just moved to a new and larger plant, but refused to let me see anything or take any pictures of the operation. That's the first time I've ever run tino anything like that and I didn't know what to make of it.

Apple Computer was a surprise . . . a corner of a garage in a home. Steve Jobs, twenty years old, designed and built the system with programming help from friend Steve Wosniak. He has some remarkably good ideas in the system and I was very impressed. I strongly suggested that they pack the system off to Atlantic City for the PC-76 show coming up. They did, and Steve came back with a bunch of orders and dealers (about 40 orders, I believe) . . . not bad! He's going to have his hands full as his company grows rapidly. Steve has promised an article on his design for *Kilobyte*.

Todd Anderson of Byte Shop #2 has promised an article on the Z-80 computer system the Byte Shops will be manufacturing soon. Todd is giving classes on the fundamentals of computers, and has promised articles for *Kilobyte* on the same subject.

One of the really exciting visits was with Bill Godbout in Oakland. He sells an incredible amount of ICs and associated parts. His warehouses are piled up to here with stuff . . . and any ham

Continued on page 173



Video generator board kits at Sphere awaiting delivery of a few more needed parts such as 7493 ICs. Parts are mounted on foam plastic with both parts numbers and values printed on a sheet on top of the foam. This makes it simple to find and use parts as the kit is assembled.

by John Craig

I/O REPORT

PERSONAL COMPUTING '76

We just returned from Atlantic City NJ after a tremendous weekend at one of the best conventions the hobby community has had yet. The convention was sponsored by the Southern Counties Amateur Radio Association of New Jersey, Inc. The whole thing was practically a three-man show, with the bulk of the work and coordination being done by John Dilks K2TQN Dave Jones WA2AML, and Jim Main WB2UON With over 3,000 in attendance, you can bet these three gentlemen (and their associates) had their hands full!

About the only thing I found lacking were booths set up for individuals to display their systems. Since ham radio is one, if not *the*, area which has found some truly interesting applications for microprocessor systems, it would seem there could have been some fascinating exhibits set up by local hams. Needless to say, an adjustment to the $100 fee for a booth would be necessary before many folks would even consider bringing their systems to Atlantic City for just show.

KILOBYTE

Personal Computing '76 provided the "launching platform" for our new magazine, *Kilobyte*. (As you probably know, the publisher of *Kilobyte* is also the man who started *Byte* magazine . . . and it turns out he has a neat sense of humor when it comes to such things as magazine names!) The *Kilobyte* booth was one of the most popular at the convention and I'm not sure if it was because we had some of the most interesting merchandise on display or because we had some of the most interesting (and cute) young ladies behind the counter! Besides the *Kilobyte* subscriptions (which were being bought left and right), we had recent back issues of *73*, computer and ham books, code tapes, and much more. We also had a *Kilobyte* drawing for a Windjammer cruise for two through the Caribbean. Byron Young of Pasadena TX was the lucky winner of that little jaunt.

One of the questions we heard most concerning *Kilobyte* was, "What is it going to provide that the other magazines don't?" It's for sure we'd be spinning our wheels if we didn't have plans for *Kilobyte* to be unique and special. One of the things we will definitely be providing through the pages of *Kilobyte* will be articles dealing with both hardware and software for the beginner. Now, stop and think about that for a moment: There are hardware types *and* software types in this computer "business" and it's very seldom that a person is well-versed in both areas. If you're one of the hardware group who enjoys designing and building state of the art circuits, it's very likely you have a lot to learn about the programming end of things. And, if you're a top-notch programmer, you probably have a lot of questions about the hardware end. (Heck, you might even have those questions if you're a mediocre programmer!) Then, of course, there's the poor guy just getting started in this whole mess who doesn't have much to carry him through except determination and a keen desire to learn.

These articles are going to be just what you've been looking for. We're not going in for straight tutorial material . . . instead, you'll be reading articles which have good practical examples we can all relate to, and good, useful, practical applications.

Kilobyte will also be covering applications in both the home and small businesses (and you can be sure that a lot of these "hobby" efforts are going to be shifting over in the direction of developing small business systems). You can be just as sure of keeping up-to-date on developments in this area through *Kilobyte*.

We're looking for programs for the *Kilobyte Software Library*. This is going to be *the* place for getting applications programs, games, educational programs, diagnostics and other software for making your home system something more than just an ol' light blinker. It's going to be a fantastic deal for you, the programmer, because you will have a means of marketing your programs and being paid a royalty on each copy sold. (These programs are going to be distributed throughout the country at computer stores, as well as being advertised and sold through *73* and *Kilobyte*.) It's going to be great for *everyone* because we'll finally have somewhere to go for the software we've all been craving!

PETERBOROUGH, NEW HAMPSHIRE

After the Atlantic City convention, I drove up to New Hampshire with *73*'s computer engineer, Jim Muehlen. This was my first trip to the northeast and I'm still in a state of shock over the fact the toll road charges we paid during that trip were almost double the cost of the gasoline!

Looking at the brighter side of things . . . let me tell you about Peterborough! It's a truly beautiful and quaint little New England town with some of the friendliest people you'll find anywhere. And, if you're ever passing through around eatin' time, be sure and stop at the *Folkway Restaurant* for some fine dishes (and some unusual company . . . such as Carl Helmers, the editor of BYTE).

The group at *73* is a sight to behold, also. Some wonderful and dedicated people put together this magazine you all enjoy so much. The house in which all this takes place is a 200 year old mansion which has more rooms than any one man could count in a lifetime. It's a beautiful place with a lot of atmosphere, and if you ever read one of Wayne's "ads" for help up in Peterborough, *you could do worse than to answer it.*

STEVE CIARCIA'S VIDEO GAME ARTICLE

The October *73* had an article by Steve Ciarcia entitled, "Hey, Look What My Daddy Built!" It described the construction of a video game using the 6 game AY5-8500 chip manufactured by General Instruments. It seems there aren't too many places where one can get hold of this chip. He (Steve) has been deluged with requests on where to get it, and the phone at *73* hasn't stopped, either. We've been told that the chip is available for $39.95 from Advanced Micro-Computer Products, P.O. Box 17329, Irvine CA 92713. The latest Heathkit video game (released in October) uses the same chip and sells for $49.95.

NEW PRODUCT REVIEW

Oliver OP-80A Tape Reader

The OP-80A "high speed" paper tape reader is probably one of the least expensive and easiest devices you're going to run across for getting programs into your computer. Unlike most other paper tape readers, you won't have to worry about mechanical repairs and alignments . . . since the movement of the tape is accomplished by pulling it through the reader. Then, on the other hand, you're not going to

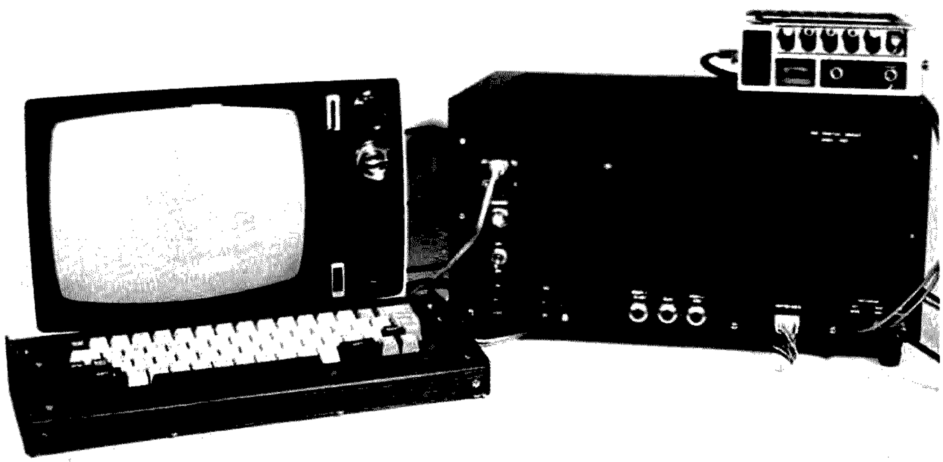
A Ham's Computer

-- CW/RTTY the easy way

For several years I have experimented with, built, and operated different items of SSTV equipment. From that experience I tried my hand at building an all solid state RTTY TVT which was recently described in *73 Magazine*.[1] In monitoring ham RTTY transmissions on the West Coast, it was noted that the subject of microcomputers and their application to ham radio was being discussed in increasing frequency. My curiosity was aroused about this new development in ham radio.

I was fortunate in being able to visit Dr. Robert Suding WØLMD several times during business trips, and observed the development of the microcomputer that is now marketed by The Digital Group of Denver, Colorado.[2] For my "hands-on" experiments in microcomputers, I purchased their type 8080-4BD kit. I feel that I was probably like other hams and did not have the slightest notion of how this thing worked, but figured to just jump in and have a go at it. I must say it has been a very interesting project. I am slowly learning to live with the new system and to use it in some practical applications.



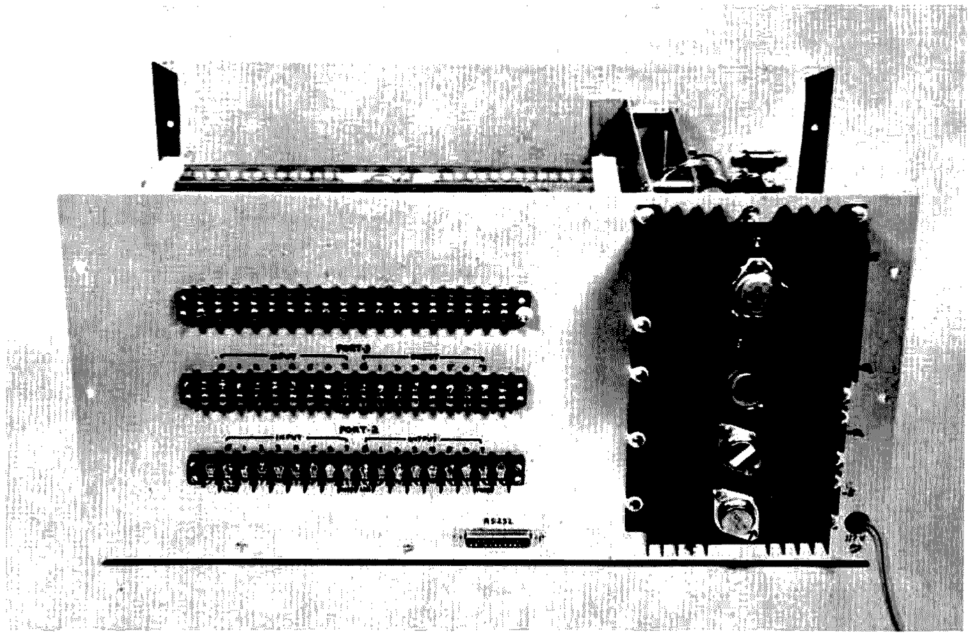
System Description

The 8080-4BD system as shown in the block diagram consists of several PC boards and the components that must be mounted on the boards. This includes the standard mother board, a CPU board with 2K of memory, an 8K memory board using 2102 ICs, a video display and cassette interface board, and a 4-port parallel I/O board.[3] The mother board will accommodate two more 8K memory boards and three more 4-port I/O boards. Low profile sockets are used for mounting all ICs. An unmounted surplus keyboard with ASCII encoded output was also purchased from The Digital Group.

A 12 inch transistorized black and white TV set was used for the video display. The display consists of 16 lines of 32 characters per line. For the cassette "Read" and "Write" modes, I use a Superscope Model C-104 as recommended in the technical literature that accompanies the kit. Power supplies in both kit and assembled form are available from The Digital Group, but I chose to build my own. The cabinet for the mother board, PC boards and power supply was salvaged from an old obsolete tube transmitter. I also fabricated a cabinet for the keyboard assembly. The TV set was modified to accept video input from the computer.

Included in the parts from The Digital Group is a prerecorded tape cassette that is used to initialize the system and to test out the memory card. It also has a game program, a program to make the unit act as a digital counter, a bicentennial demonstration program, and a ham CW and RTTY program. The bicentennial program on the tape prints an American flag on the TV screen to the accompaniment of *The Star-Spangled Banner*. As Dr.

Suding says, "So what else would you expect in 1976?"



Assembly of the System

It is stressed in the data furnished with the kit that the builder should have some experience in building electronic equipment other than assembling detailed kits from Benton Harbor. The data does not give that kind of step-by-step instructions. The quality of the PC boards is first class, with gold-plated connector contacts and double-sided boards with through-plated holes. General instructions on how to assemble each PC board are given, with a description of how the circuit works. A schematic diagram is furnished for each board, along with a general parts layout for that particular board. Testing and troubleshooting information is also furnished in the data package.

In assembling my system, I discovered one board that was missing all the bypass capacitors. They were immediately replaced when The Digital Group was advised of the shortage. Another board had one low cost IC missing which I replaced from my junk box. Another board had one extra IC in the kit. After the unit was finally assembled and ready to test, I ran into several bugs. The characters on the video monitor were not complete, and it looked more like a foreign language than English. I found, after consultation with Dr. Suding, that I had a bit missing on the data lines going into the video board. This was determined to be caused by a lack of through-plating in one of the holes in the mother board. The next bug was that a portion of the dot structure was missing in the characters being displayed. This was found to be caused by a defective Motorola (MCM 6571L) character generator chip which was promptly replaced (once again) by The Digital Group. The last bug was that the encoder chip (TI TMS-5000) in the keyboard had to be replaced (as one row of keys was dead). With those bugs out of the way the system worked as designed.

The power supply shown in the diagram was homemade, and provides all the voltages required at the specified current loads. I had to salvage an old 6.3 volt 20 Amp transformer and rewind it with a new secondary for the high current 5 volt load. A second winding was also added for the +12 volt line. The crowbar circuit was added to protect all those expensive ICs on the memory and CPU card. Discussions with Dr. Suding indicated that anything less than 50,000 uF in the 5 volt power supply filter might lead to unwanted noise problems. I located just what was needed in a local surplus store and ended up with a 55,000 uF unit.

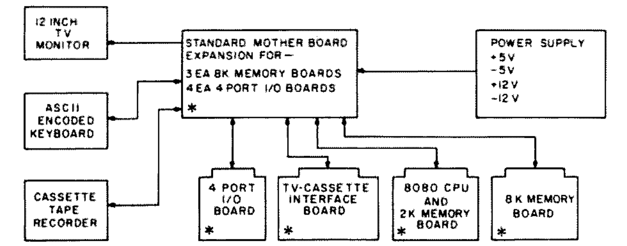


*Fig. 1. Block diagram of microcomputer system at K7YZZ. *Items basic to the 8080-4BD kit.*

The cabinet for the computer is 18½ inches wide by 9 inches high by 12 inches deep. I cut two large square holes in the top and riveted in a perforated grille for better circulation of cooling air. A 4 inch fan is mounted on the compartment divider bulkhead between the power supply compartment and the PC board compartment. The air is directed over those warm memory chips. I have had no problems with overheated ICs. The MPC-1000 5 volt 10 Amp regulator is mounted on a very large heat sink on the back bulkhead, out in the open air. This way it does not dump its heat into the unit.

The 12 inch TV set was modified as per a TV typewriter article in *BYTE Magazine.*[4] The level of the video signal from the computer was more than the TV set could handle, and required additional line loading before the set began to display the signal on the screen at an acceptable brightness and contrast level. The builder should *not* use a TV set that does not have a power transformer providing power line isolation. Be sure that the set does not have a "hot" chassis with series string heater tubes. That type will really fry the ICs in a computer.

I found that when playing the cassette into the computer I could not monitor the audio signal, so I modified the recorder by adding a 100 Ohm resistor across the output jack switch contacts so that the speaker was in the circuit even when an audio line plug was connected to the recorder output. It is convenient to monitor the mark frequency tone as the program playback begins and ends.

Initial Test

When power is applied to the system there should appear on the top of the TV screen "Read 8080 INITIALIZE Cassette." If this message appears, all is well. The first program on the audio cassette furnished with the kit is loaded in the recorder. At the start of the mark frequency tone the "Reset" button on the com-

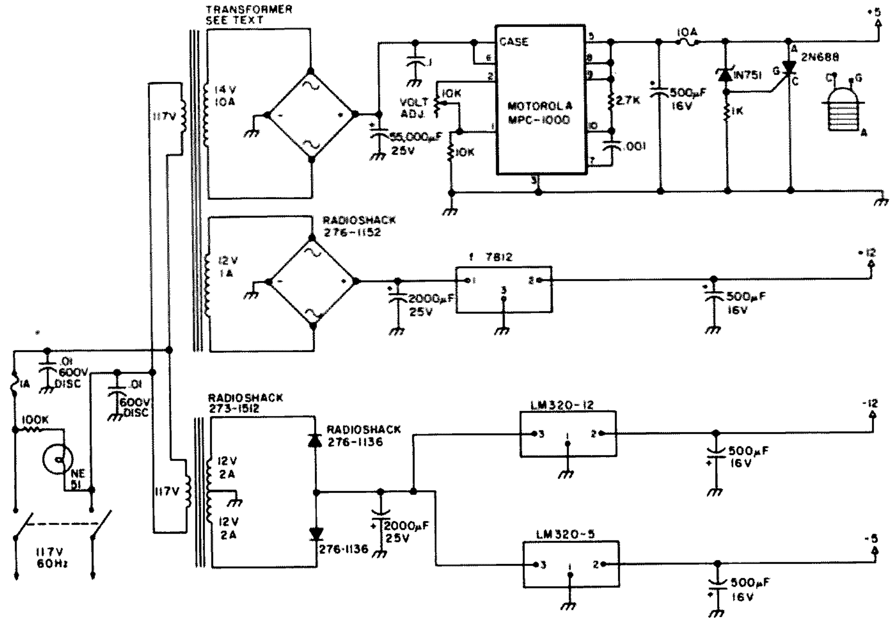

Fig. 2. Power supply for The Digital Group 8080-4BD.

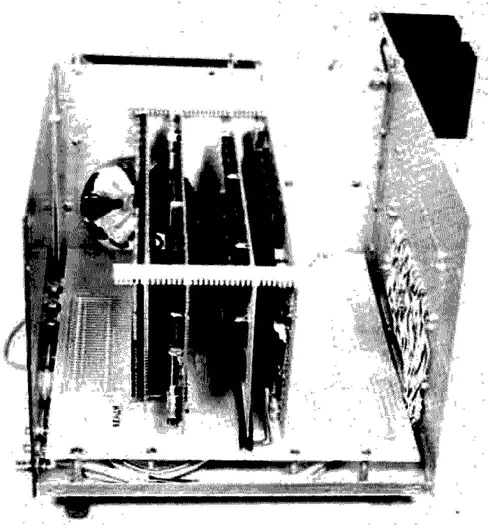
puter is depressed for a moment. The computer then begins to accept the digital data recorded on the tape. As the data is loaded into the computer, the TV screen will display lines of a running series of numbers beginning with 1 through 7, and back to 0 through 7, until the program is loaded. This represents each page of program data being loaded into memory. At the end of the program tape, the mark tone will return and the screen will display "8080 OP SYSTEM" and the options. Selecting item 4 of this listing (hit key 4) will permit the operator to begin generating a program from the keyboard beginning at page 6. Program development using this tape will be in the octal code format. Other prerecorded programs on the tape, such as the "Memory Check," are used to determine if all of the memory ICs are OK. The tape for that program is loaded and key 6 is depressed. The TV screen goes blank until all the memory chips are tested. Then, if all is OK, an alpha sign appears in the upper left hand corner of the screen and another run is automatically begun. Each successful test provides another alpha figure on the screen. For the 2K memory the check time is just a few seconds; for the 10K memory it takes about a minute to run the test. If a defective memory IC is located, it will stop the test and print on the TV screen which IC is defective and on which circuit board the IC is located. This really works, as I tried some known bum chips and it located them very promptly.

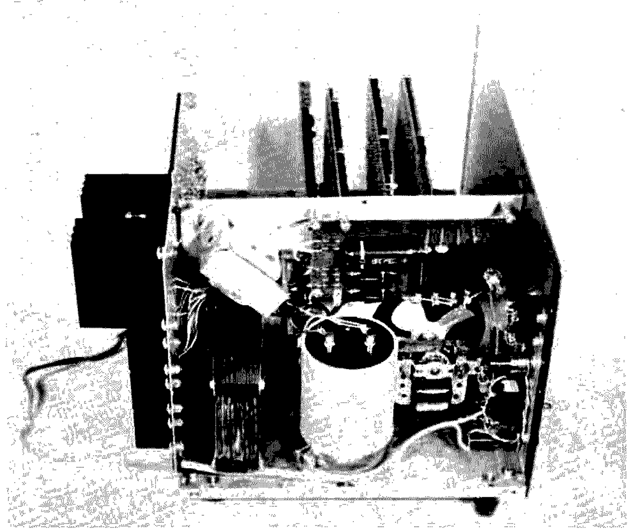
At first I was very apprehensive about pushing that "RESET" button, or switching off the power to clear the memory for a new program entry, but after a while I found that it did not damage the machine. I became more confident of the machine and its operation.

Operation

The Digital Group has established a branch called The Digital Group Software Systems, which supplies cassettes of games and other items, such as a Tiny BASIC Extended.[5] I obtained all the games (that are available to date), including the Tiny BASIC Extended. Most of the games are written in Tiny BASIC and must have the Tiny BASIC program loaded in the computer before they can be played. The machine is turned on, and when the initialization statement appears on the TV screen the Tiny BASIC tape is loaded. Then the selected game tape is loaded by keying 1 on the keyboard when the mark tone appears at the beginning of the tape.

The blackjack game is fun to play, and some of the locally trained (Las Vegas) experts tell me it is a very well written program. It has all of the game's rules well executed. I condensed all of my games onto two tapes. I recorded the Tiny BASIC program at the beginning of each tape and then recorded around 10 to 12 games on each tape. There is still plenty of tape left for additional games. The magnetic tape cassettes are of the 30 to 46





minute type. Longer tapes are too thin to make good recordings of digital data.

A new ham cassette is in the works at The Digital Group Software Systems[6] and will have expanded capability for both sending and receiving CW and RTTY (with up to 8 storage slots of 100 characters each).

I have had some success at trying to program some games using the Tiny BASIC Extended. (Incidentally, the Tiny BASIC Extended does not have floating decimal or square root math capability.) I feel that these programming efforts have been the most informative and effective way to learn just what you can and cannot do with the machine. Also, you can be sure that it will tell the operator when he has goofed, in no uncertain terms.

Conclusions

The construction of the microcomputer turned out to be no more difficult than most SSTV construction projects. The biggest problem is acquiring an understanding of the machine and learning the Tiny BASIC Extended language. Computer terminology is almost like listening to a foreign language. I can assure the reader that after continued exposure to this new technology the terms and functions will begin to make sense. I should also like to warn the reader that this machine is addictive. You will find yourself sitting in front of that keyboard for hours trying out first one thing, then another. It is absolutely fascinating. Try it, and see for yourself. ■

What's All This LSI Bunk?

-- an ostrich's eye view of the microprocessor

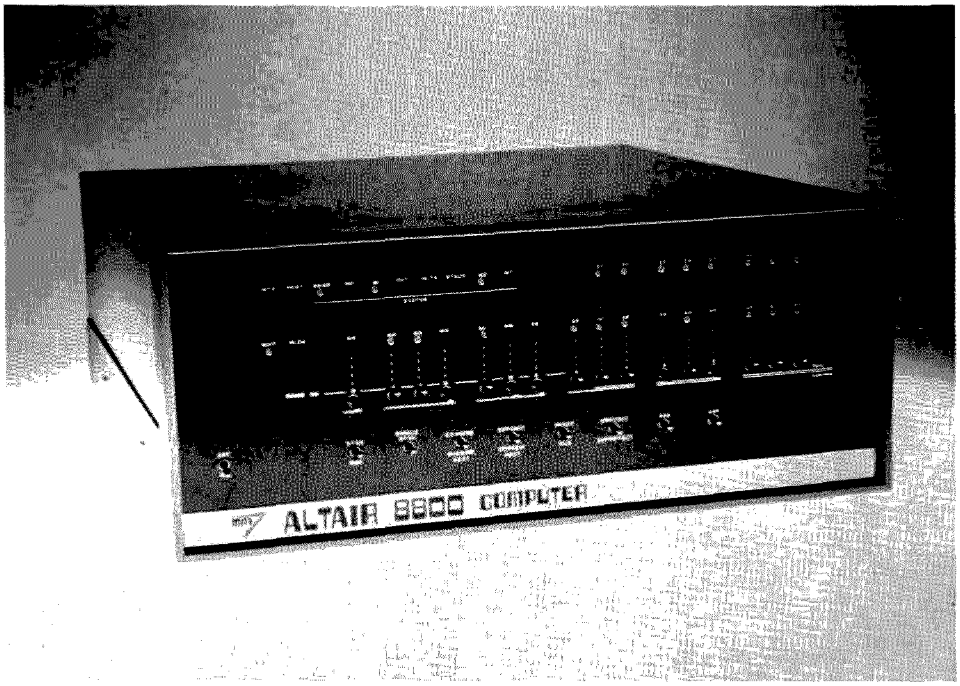

Fig. 1. The MITS Altair 8800, the first home computer (courtesy of MITS, Inc.).

Last year a small company called MITS introduced a new product that may eventually be as exciting as the first crystal radio, first FM receiver, or the first television set. The product was a computer in kit form that cost less than $500. Fig. 1 shows the completed version of the MITS Altair 8800. In this article we will explore how such inexpensive computers became possible and how we can use these new devices. The science fiction dream of a home computer has become real; already hobbyist clubs and stores that specialize in home computers have sprung up across the country. The world of computers, which was formerly only open to large institutions and specially trained experts, has suddenly become open to anyone with some time and some space in a house or garage.

Let's start at the beginning (last year!). How, in these days of 75¢ loaves of bread and $3500 Volkswagens, can a computer cost less than $500? In fact, prices for computers and such items as printers, television displays, and extra memory continue to go down. We can now buy computers and the devices that go along with them from many sources for prices that seem incredible.

The main reason for these developments is the emergence of large-scale integration (LSI) in semiconductor technology. Fig. 2 shows some of the developments in large-scale integration in the last ten years. Manufacturers can now place the equivalent of 10,000 transistors on a

piece of silicon less than a quarter of an inch square; this number has doubled each year for the last ten years and is likely to continue doing so for the next ten years. LSI has already led to the electronic calculator and the electronic watch. In the early 1970's, semiconductor manufacturers found it possible to place circuitry that would perform all the functions of the central processing unit (CPU) of a computer on one or a few chips. We call such computers on a chip *microprocessors.* Fig. 3 is a photomicrograph of the Motorola 6800, one of the most popular microprocessors; note the tremendous amount of detail present in a device with an area of less than one twenty-fifth of a square inch. Almost two years of work goes into the design and testing of such a device; however, once designed, the chips can be produced at the rate of thousands per hour for a manufacturing cost of a few cents apiece.

A Brief Historical Perspective

The main reason for the low price of hobby computers is the use of microprocessors. A microprocessor will fetch instructions from memory and decode them, accept data from memory or outside sources, perform arithmetic or logical operations and save the results in memory or send them to external displays or other devices. A microprocessor will thus do everything that a large central processor will do, even those which are the heart of enormous computers like the IBM 370, Burroughs 6700, or Control Data 7600. Yet the microprocessor is built on one or a few chips of silicon and costs only $10 to $100.

The microprocessor is an outgrowth of MOS LSI technology. MOS, metal oxide semiconductor, is the name for a device fabrication process which allows very complex devices to be placed on a single chip. The MOS LSI technology uses masking processes which we can compare to those used in photography. The manufacturing cost of MOS LSI devices, like the developing costs of photographs, is relatively independent of the amount of detail involved. The cost of developing a picture with a million precise details is the same, in terms of paper and chemicals, as the cost of developing a picture taken without removing the lens cap. Of course, the more detailed photograph requires a better camera, more attention to layout, and greater photographic skill; it is also less likely to turn out correctly. The production of complex MOS LSI chips is similar to the development of detailed photographs. Since the production cost of a complex chip is not markedly different from that of a simple chip, the more that can be placed on a single chip, the cheaper the overall system will be. Such a single-chip system will require fewer packages and connectors, less power, less labor, and a smaller amount of other supporting circuitry and equipment. LSI thus results in lower total cost if we can use the same LSI devices over and over again. LSI-based systems will also be smaller, cheaper to run, and more reliable.

MOS LSI techniques were first used to create compact, low power memories. In the late 1960's, these techniques were used to create electronic calculators; the first such devices were multi-chip systems which retailed for several hundred dollars but could do little more than today's $10.00 or $15.00 devices. Remember that just ten years ago the large mechanical calculator and the slide rule were the state of the art. In the early 1970's, the quickly changing calculator market made semiconductor manufacturers look for new ways to produce more general and more flexible devices which could be produced in large volumes

Table 1. Manufacturers of educational and hobby microcomputers. Note: Many of the largest manufacturers of microprocessors and microcomputers are not included in this list because their products are intended for industrial applications.

and yet could be modified by the calculator manufacturers to meet new or custom requirements.

The first microprocessor, the Intel 4004, was developed for a calculator manufacturer. Although it was designed primarily for the calculator market, it was programmable; its actual functions could be changed by the calculator manufacturer rather than being fixed by the semiconductor manufacturer. The power of the microprocessor and its advantages over hard-wired design soon became evident to other industries. The first 8 bit microprocessor (the Intel 8008), directed largely toward manufacturers of computer terminals, was introduced in 1971.

The complete history of the microprocessor is thus only five years long. Already, though, processors are in common use which are a hundred times as powerful as the early 4004 and 8008; such processors can do more than could large computers of 15 years ago which cost (in uninflated money) over $100,000.00. Nor have we yet come close to reaching the limits of microprocessor performance; many of today's limitations will disappear as manufacturers continue to produce more complex LSI chips.

A Microprocessor Survey

Let's take a look at some of the existing microprocessors from the hobbyist's point of view. We will pay particular attention to those microprocessors which are widely used as central processing units in hobby computers.

Current microprocessors can be divided into three

First Memory Chips (256 bits)	First Multi-chip Calculators	First Single-chip Calculators	First Microprocessor (Intel 4004)	Intel 8080	Motorola 6800	
			1K Memory Chips	4K Memory Chips		16K Memory Chips
1966	1968	1970	1971	1973	1974	1975

Fig. 2. LSI developments from 1966 to the present.

basic categories:

(1) Calculator-like processors
(2) Standard, self-contained processors with a fixed instruction set
(3) Bit-sliced processors and others with a user-defined instruction set

The three categories include a wide range of computing power, speed, price, and application areas. Category 2 contains all of the microprocessors used in hobby computers. Therefore, we will briefly describe categories 1 and 3 and focus our attention on category 2.

Category 1, the calculator-like processors, contains the simplest and cheapest devices. Typical processors in this category are the Intel 4004 and 4040, Rockwell PPS-4, Texas Instruments TMS-1000, American Micro-Systems 9209, and National SC/MP. Many of these devices are much like calculators; they are often specially designed or have special instructions to handle keyboards and lighted displays and to perform simple decimal arithmetic. However, these microprocessors are user-programmable (unlike calculator chips) and can be used in a wide variety of applications. Besides advanced calculators, such devices have been used in character printers, games, household appliances, paper tape readers, test sets, function generators, counters, microfilm readers, telephones, tuners, valves, scales, cash registers, and time and attendance terminals. We may have hundreds of these devices in a single store, factory, or laboratory.

The devices of category 1 represent the smallest amount of computing power that can be purchased as a single unit. Complete systems based on these devices cost only $5 to $30 in large quantities. They are used mainly in applications requiring low cost, low speed, and relatively limited processing power. Such microprocessors are most often found in large volume applications as simple controllers for systems whose speed is limited by human interaction or slow mechanical devices. These processors generally have very short word lengths (most can only handle 4 bits at a time) and are thus unsuited to systems requiring complex calculations, high data rates, or great accuracy. Although these simple processors do not attract much attention from writers or researchers, they are still probably the most widely used in terms of volume because of their low cost.

We should note that computer speed is relative. We often call a computer slow if it can only execute 100,000 instructions a second! A large computer may be able to execute 10,000,000 instructions in that same time but the "slow" computer still seems to work at lightning speed to the average observer.

Category 3, the bit-sliced processors, are largely intended as building blocks for special-purpose computing elements. Typical microprocessors in this category are the National IMP, Intel 3000, Advanced Micro Devices 2900, Monolithic Memories 6701, Texas Instruments SBP0400, and Fairchild Macrologic. Unlike the devices in categories 1 and 2, the bit-sliced processors are not self-contained CPUs. Rather, they involve a whole family of elements including a 2 or 4-bit processor slice which the user must combine to form a CPU. Such a CPU will generally involve 30 to 50 discrete packages. These microprocessors are thus intermediate between the self-contained CPUs and the discrete circuitry that is currently used to make large computers.

Most of the bit-sliced processors are much faster than standard microprocessors, but significantly more expensive and harder to use. CPUs based on these processors typically cost $500 to $1500. Typical applications include disk controllers, minicomputer CPUs, test equipment, intelligent terminals, and signal processing equipment. In the near future, the bit-sliced processors may become the basis for most minicomputers. However, the cost and the number of elements required for a CPU will have to be significantly reduced before such devices can be used in hobby computers.

The main category of microprocessors with which hobbyists are presently concerned is category 2, the standard, self-contained processors with a fixed instruction set. These processors are intermediate in performance between calculators and minicomputers (i.e., between categories 1 and 3). They are complete CPUs on one or a few chips and require only a small amount of supporting circuitry. Prices range from $20 to $200 in single quantities (not including memory, I/O, or other system requirements). Most of these devices will handle 8 bits of information at a time, although a few can handle 16 bits at once. The most widely used microprocessors among hobbyists are:

Intel 8080 (the Intel 8008 is an older, less powerful version)

The Intel 8080 was the first device in this category to be introduced (in 1973) and is the most widely used CPU in hobby computers. It is used in the MITS Altair 8800, IMSAI 8080, and in similar sets from Martin Research and other sources. The Zilog Z-80 is an extended version of the Intel 8080 with a larger, more powerful instruction set and other extra features.

Motorola 6800

The Motorola 6800 is comparable to the Intel 8080 in performance (it was first introduced in 1974). It is used in the MITS Altair 680 and other hobby sets from Southwest Technical Products, Sphere, Wave Mate, and Ohio Scientific Instruments.

MOS Technology 6502

The MOS Technology 6502 is also comparable to the Intel 8080 and Motorola 6800 in terms of performance. It was first introduced in 1975 and is used in the JOLT hobby computer and others. The MOS Technology 6502 is somewhat cheaper than either the Intel 8080 or Motorola 6800, but not as widely used.

National PACE

The National PACE is slower than any of the previously mentioned processors and somewhat more expensive. It will, however, handle 16 bits of information at a time (the others handle 8) and has a more powerful instruction set. Systems based on this processor are available from Godbout Electronics and from Hamilton-Avnet (the Pacer).

Intersil 6100

The Intersil 6100 is a new device which executes all the instructions of the world's most popular minicomputer, Digital Equipment Corporation's PDP-8. The advantage of the Intersil processor is that a tremendous number of programs are already available for the PDP-8. Systems based on this processor can be obtained from PCM Corp. or Ohio Scientific Instruments.

Other processors in category 2 which may eventually be used in hobby computers include the Rockwell PPS-8, Signetics 2650, RCA CDP 1802 (COSMAC), Fairchild F-8, and General Instrument CP-1600. Table 1 contains a list of some manufacturers of hobby computers and the processors they use. A new entry in this category is the Texas Instruments TMS9900 which handles 16 bits at a time like the National PACE but is just as fast as the Intel 8080 or Motorola 6800. The TMS9900 is presently more expensive (about $200 in single quantities) than the other microprocessors mentioned above, but offers much more processing power.

Of course, the devices in category 2 have found many applications besides hobby computers. Among the more common are monitoring systems, line printers, navigation systems, business machines, test equipment, security systems, programmable terminals, plotters, oscilloscopes, machine tools, industrial-control systems, message switching units, graphics terminals, and medical instruments. These processors will probably continue to have the widest variety of applications in the near future.

Semiconductor Technologies

Now let's examine the characteristics of the semiconductor technologies from which microprocessors are produced. The importance of particular features will be described as well as technological trends that may be of significance to hobbyists.

The first question that must be answered is, "What characteristics are desirable in a semiconductor technology?" Some desirable characteristics are fairly obvious:

Low cost: If devices from a particular technology can be produced cheaply, the ultimate cost will be lower. Cost depends on the complexity of the semiconductor processes and on the amount of experience that has been acquired with a particular process. We should note that semiconductor prices vary widely and manufacturers' list prices often don't closely follow the actual prices charged by distributors or supply houses.

High Density: If more complex circuits can be placed on a single chip, fewer devices will be needed to perform useful functions. More complex chips are not usually much more expensive to manufacture, but require fewer packages, fewer connections, less board space, and less power than a larger number of simple chips.

Low power consumption: If the circuits produced from a particular technology require less power, they will need smaller power supplies, use less energy, and produce less heat. Devices that use large amounts of power will need expensive power supplies and special cooling mechanisms such as fans or air conditioning.

High speed: If the devices run faster, they can simply perform more work in a given amount of time.

Even these simple characteristics can't be easily combined – devices that run at high speeds usually dissipate a lot of power, for instance. Technologies that result in high speed also typically result in low density and relatively high cost. Tradeoffs will have to be made.

Other useful features in a technology that may not be quite so obvious include:

Compatibility with standard TTL circuitry: If devices made from a particular technology can be readily used with the standard 7400 series TTL integrated circuits, they can then be easily and cheaply interfaced to peripherals and other circuitry.

Ruggedness: If devices made from a particular technology are more rugged, they will be able to withstand temperature variations, moisture, power surges, noise, and shock. Devices that are vulnerable to various conditions will have to be protected by means of special circuitry or packaging.

Wide availability and support: Technologies that are produced by many suppliers and heavily supported will have more parts available, more compatible devices, and lower prices. Such a technology is likely to continue in use for many years.

Standard parts and large memories in the same or compatible technologies: Technologies that have such devices will be relatively easy to use in complete computer

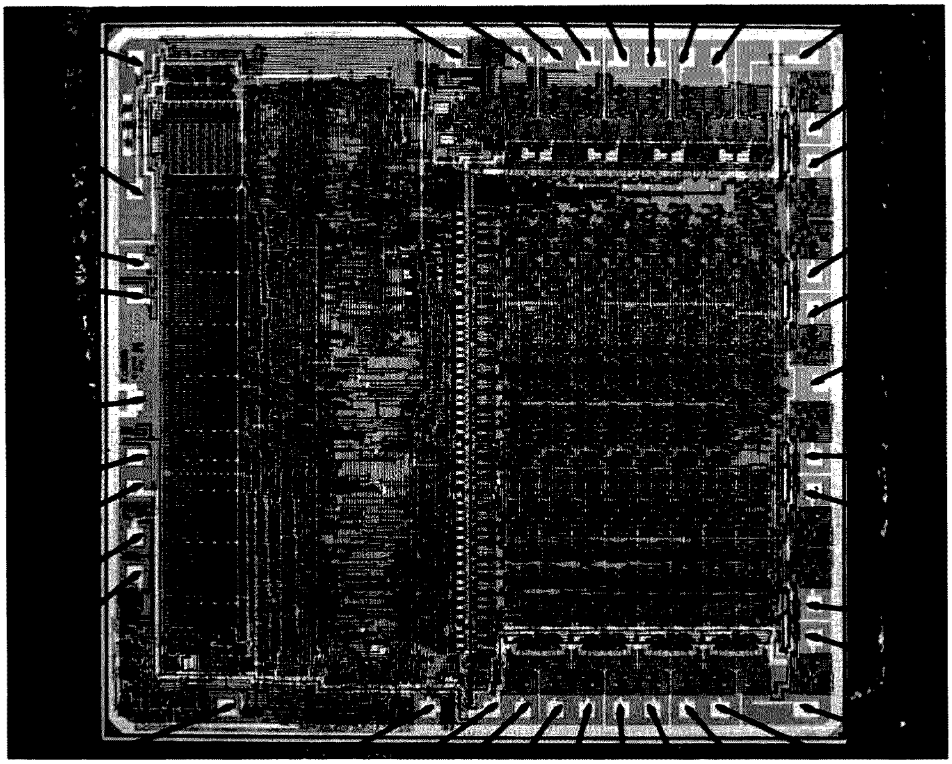

Fig. 3. A Photomicrograph of the Motorola 6800 microprocessor (courtesy of Motorola 6800 Semiconductor Products, Inc.).

systems.

Microprocessors are currently available in six different technologies:

PMOS (P-Channel Metal Oxide Semiconductor): the oldest MOS technology; high density and low cost but relatively low speed; not TTL compatible.

NMOS (N-Channel Metal Oxide Semiconductor): the present state of the art MOS technology; high density and moderate cost and speed; can be made TTL compatible.

CMOS (Complementary Metal Oxide Semiconductor): a technology widely used when low power consumption and high noise immunity are needed; medium · in density, cost, and speed; can be made TTL compatible.

Schottky TTL (Schottky Transistor-Transistor Logic): a variation of standard TTL that offers high speed, but high power consumption and cost and low density; fully compatible with standard TTL.

ECL (Emitter-Coupled Logic): A very fast technology that is very expensive and consumes a large amount of power; not compatible with TTL.

I^2L (Integrated-Injection Logic): a new technology that may ultimately combine the speed of TTL with the density of MOS.

A comparison of these technologies is shown in Table 2. Clearly, PMOS and NMOS rank highest in the important categories of cost and density, CMOS ranks highest in ruggedness and lowest in power consumption, ECL is the fastest, while Schottky TTL is the easiest to interface.

	PMOS	NMOS	CMOS	Schottky TTL	I^2L	ECL
Cost (1 = Lowest)	1	2	4	3	5	6
Density (1 = Most Dense)	2	1	3	4	4	6
Power Consumption (1 = Least)	3	4	1	5	2	6
Speed (1 = Fastest)	6	5	3	2	3	1
TTL Compatibility	No	Sometimes	Sometimes	Yes	?	No
Ruggedness (1 = Most Rugged)	5	4	1	3	2	6
Availability and Support (1 = Most)	4	3	2	1	6	5
Standard Parts and Memories (1 = Most)	4	3	2	1	6	5

Table 2 Comparison of semiconductor technologies.

At the present time, NMOS seems to have the most desirable combination of characteristics. It is relatively cheap, very dense, consumes little power, can be made compatible with standard TTL circuitry, and has a family of large compatible memories. NMOS can be used to make single-chip microprocessors which run at reasonable speeds. Such commonly used microprocessors as the Intel 8080, Motorola 6800, MOS Technology 6502, and Fairchild F-8 are made from the NMOS process.

Furthermore, new developments in the NMOS technology should lead to considerable improvements. NMOS memories (like the Intel 2115) are now available that are as fast as memories made from Schottky TTL. The maximum size of the chips that can be produced from NMOS has also been increased. New NMOS processes have been introduced that can be easily interfaced with standard TTL circuitry and can use standard TTL power supplies. Significantly increased performance can be expected in the next few years from NMOS microprocessors.

As for the other technologies, the ones that will probably be the most interesting to hobbyists are CMOS and I^2L. Only a few processors (most notably the RCA COSMAC and Intersil 6100) are presently available in these technologies, but none has been widely used in hobby computers. However, single-chip microprocessors would appear to be possible in both technologies at relatively low prices. Such processors would not only be faster than NMOS processors, but would also use substantially less power and would be much more rugged. Microprocessors and large memories in these technologies may become available to hobbyists in the next few years. ■

visiting views from around the globe

from page 9

Wednesday and said he was told at the hospital that it did not have the proper equipment to treat Carden.

By that time, Smith and other hams had managed to get Carden's bail reduced from $9,000 to $2,700. But after appeals on the air only $1,700 had been pledged.

When Johnston learned that the courts in Mexicali were to close yesterday for a 30-day recess, he decided to go there and plead with Judge Rafael Moreno Henriquez, chief justice of the Superior Tribunal.

"Why should this boy lie there and pay with his life for a minor crime?" Johnston said he asked the judge.

Reduce the bail to an amount the hams could pay, Johnston pleaded. The judge agreed to do so. "He was a fine gentleman," Johnston said. He added that all government officials in Mexicali cooperated to the fullest to free Carden.

Johnston, who is coordinating the fund-raising effort, said that he had only $22 in hand from pledges made to him over the radio.

The 17 $100 bills used to free Carden yesterday were supplied by one ham who asked to remain anonymous. He is confident that the pledges will be made good.

Another ham told Hower he would make good any shortfall between the pledges and the bail.

Hower said the hams are not judging whether Carden is guilty. "If you find a man bleeding in the middle of the road, you help him," he said.

As word of the mission of mercy spread, Johnston got a call from a man in Oregon yesterday.

"He asked me if the company that rescued Robert could also save a man in Acapulco," Johnston said. "I told him that we are not a company, but a fraternal order just trying to be of service."

The hospital was to check today to see if Carden is a former serviceman entitled to VA treatment.

If he is, about the only reason he could be turned out of the hospital and refused treatment would be if he had been dishonorably discharged, a hospital spokesman said.

The Soft Art of Programming

-- part III

(Here's the final installment of Rich Didday's series on BASIC programming. The article is written around a record-keeping program for computer club members . . . but the concepts presented will be applicable in many other areas as well. For the beginner, a lot can be learned from reading and analyzing the program — which holds true for experienced programmers, too. I'd like to invite you readers who sit down and develop the machine language routines for cassette read and write to submit them for publication. OK? — Ed.)

What we've been doing: In Part I we went over ways of learning the individual elements of the programming language BASIC, emphasizing that good programming involves planning things out long before you ever write any statements in BASIC (programming is a lot more than just coding). We played around. We had fun.

In Part II we began to put together sequences of computer instructions (BASIC statements) in order to carry out a substantial, useful task — namely, the record-keeping requirements of our computer club. We saw ways of using arrays, ways of estimating how much memory our program would need for data storage, ways of cutting down on memory usage. We got frustrated.

In this, the concluding part, we'll finish the record-keeping program by pulling together the ideas we laid out last time, with some major improvements. We'll emphasize the notion of

developing our program part by part, keeping the user's convenience and our overall objectives clearly in mind. We'll be satisfied, ready to go onward and upward.

At last! We're finally ready to finish our record-keeping program. Before plunging into the details of the finished program, let's be sure we have the big picture firmly in mind.

Fig. 1 shows the organization of our "data bank." There is a *record* for each member. Each record consists of six *fields* which store specific information about that member. A *file* consists of some number of records, the only restriction being that the number of records on a given file can be no more than will fit in memory at once. We'll store each file on a separate cassette tape, so we'll use the terms *file, tape,* and *tape file* pretty much interchangeably. In addition to the tapes storing membership records, there is one more which stores a *directory* which we'll use to enable our program to decide which tape file it needs to find a specific member's record. The directory tape together with the membership record tape files make up the *library.*

Our program must initialize and maintain the library, calling for and rewriting tape files as the need arises (based on the commands the user gives at the terminal). The four commands ADD, DELETE, LIST, and END seem sufficient for our needs. Fig. 2 describes each command and shows the basic structure of the program.

So far, the only difference from last month's plan is the inclusion of a directory. It is a big difference, though, because the directory, coupled with a more reasonable way of organizing the records (namely, keeping them in alphabetical order instead of in no order like last time), will make the system much more convenient to use. For now, let's follow through in a "top-down" way and code the main structure of the program, the part shown in the flow chart in Fig. 2. We'll leave the details for subroutines which we'll work out one by one. This general strategy is sometimes called "top-down programming" and sometimes "modular programming." The idea is that by breaking the problem down into manageable chunks, you're less likely to get confused, and more likely to keep all your objectives in mind as you go.

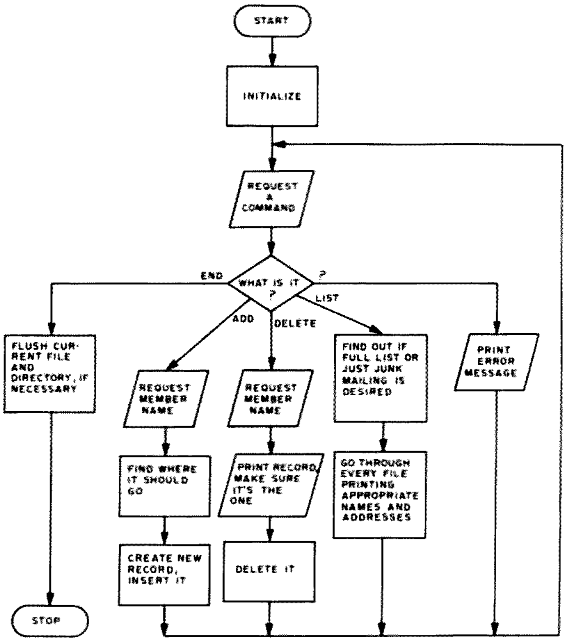
The Main Program

The main program begins by declaring the arrays to store membership records (exactly the same as last time) and the arrays which hold information about each file (i.e., the directory information). The next step is to initialize a number of the variables which we'll use to minimize the number of tape operations required. Also, there is a variable which you'll have to tailor to your own system: RI, which tells how many records can fit in memory at once.

The next thing the program does is determine how to initialize the directory information. If this is the first use of the system ever, there is no directory tape yet, so the program fills zeros into the appropriate parts of the directory, and gets ready to start creating the first file (which will eventually be stored on cassette tape number 1). If, on the other hand, the system *has* been used before, there will be a tape with the directory information on it, and the program requests the user to mount it and read it in.

Next, the program offers to print a summary of the available commands (that's handled by the subroutine which starts at statement 3000, which we'll get to soon).

Finally, the program enters the main loop (starting at statement 2000) which asks for a COMMAND, interprets it, and carries it out. The program segment for the END command begins at statement 2040, the code for the LIST command begins at 2200, the ADD at 2450, and the DELETE at 2570. If the user types in an invalid command, control passes to state-



Command	Action Taken
END	End of run. If the file currently in memory has been altered in any way, write it out to its cassette tape. If the directory has been altered, write it out also.
ADD	Insert a new record. Ask for the new member's name, figure out what file it goes on. If that file isn't in memory, get it. Get the rest of the member information and insert the new record in alphabetical order.
DELETE	Remove a record from the library. For safety's sake, print the whole record and ask again before deleting it.
LIST	Generate a mailing list. Go through the entire library, starting with tape file 1, printing names and addresses of appropriate members.

Fig. 2. Basic structure of the record-keeping program with each command described.

ment 2750.

The statements which handle the commands make frequent use of subroutines to carry out the details. As you go over the statements, keep referring to the flow chart in Fig. 2 to see how things fit into the overall scheme. Incidentally, even if you have no plans whatsoever to implement this program on your own machine, you'll learn a lot by making sure you see how the program works, and by trying to redo parts of it in different ways, seeing if you can make it cleaner and more useful. (I'm happy with it the way it is, but everyone's taste and specific needs differ.)

2770    GO TO 2000
```

The Command Summary Subroutine

The subroutine which begins at statement 3000 simply prints a summary of the available commands. Depending on your taste, it could be made more extensive, and include such details as how to load and start your cassette tape equipment, how to store the tape files, and so on. On the other hand, if your system will be used only by people who are very familiar with it, the subroutine could be shortened.

```
3000 REM  COMMAND SUMMARY SUBROUTINE
3010 PRINT "WANT A SUMMARY OF COMMANDS";
3020 INPUT Z$
3030 IF Z$ = "NO" THEN 3140
3040 PRINT
3050 PRINT "***** COMMANDS *****"
3060 PRINT "END     BE SURE TO GIVE THIS AS"
3070 PRINT "        YOUR LAST COMMAND"
3080 PRINT "ADD     ADD A NEW MEMBER"
3090 PRINT "DELETE  DELETE A RECORD"
3100 PRINT "LIST    GENERATE A MAILING LIST"
3110 PRINT
3120 PRINT "NOTE: TO CORRECT OR UPDATE A"
3130 PRINT "MEMBER'S RECORD, 'DELETE' AND THEN 'ADD'"
3140 RETURN
```

One difference from last month's scheme is that there's no longer an UPDATE command for altering a member's record. Since we're now keeping the records in alphabetical order, the UPDATE command isn't as simple as before – if the spelling of the member name changes, the program would have to remove the old record and insert the changed version of it in the proper place. It seemed simpler to me to just provide a DELETE command and let the user do updates with it. Again, it's a matter of taste. If you feel that you'd rather have an UPDATE command, or you'd like to add some other command, the way the main program is organized makes it easy to do so. For example, suppose you want to add a command called PRINT which asks for a member's name and then prints the corresponding record. All you'd have to do is insert an appropriate test at statement 2750, insert the appropriate statements at that point, and shift the statements which handle illegal commands down to the end, like this:

```
2750 IF C$ <> "PRINT" THEN 2860
2760    REM  "PRINT" COMMAND: GET MEMBER NAME, LOCATION
2770    GOSUB 4000
2780    PRINT N$(I)
2790    PRINT A$(I)
2800    PRINT B$(I)
2810    PRINT D$(I)
2820    PRINT S$(I)
2830    PRINT L$(I)
2840    PRINT
2850    GO TO 2000
2860 PRINT "SORRY, BUT "C$" ISN'T A COMMAND."
2870    GOSUB 3000
2880    GO TO 2000
```

The Get Name, File, and Location Subroutine

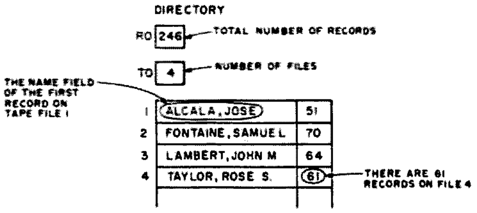
This subroutine performs a fairly simple task conceptually – namely, getting a member's name from the user and then finding where it goes. However, since the right file may not be in memory, it can take a fair amount of thrashing around to accomplish this task.

Getting the member's name is easy, but how do we use the directory to discover which file that member's record should be on? The F$( ) part of the directory gives the first member on each file. We begin by considering file number 1 (the variable T2 stores the number of the tape file we're considering). If there is only one tape file, then we're done – the member must go on file 1. If there are more, we get to line 4080. If the name we seek comes before the first name on file 2, we're done – again, the member must go on file 1. If on the other hand, the name we seek

---

There are two assumptions that heavily influence the design of the record-keeping program. First, I've assumed that (eventually) there will be many more records than will fit in memory at once. If in your particular application that's not true, you can simplify the program substantially (you no longer need the directory, the update procedure, nor any of the elaborate tape requesting and dumping machinations).

The second assumption is that we have only one simple, slow cassette recorder to work with. That means that any extra work the program can do to avoid reading or writing tapes will be well worth the effort. By keeping the records in alphabetical order and by keeping a directory showing where each tape file starts, we can figure out what tape file a particular name goes on immediately, with no extra tape reads. By keeping track of whether or not a file in memory has been altered, we can avoid any unnecessary tape write operations.



The directory at a particular point in time.

Other Key Variables:

D1	= 1 if directory has been altered at any time during the current run.
T1	= 1 if the tape file in memory has been altered in any way.
R1	= the maximum number of records per file.

Dec 1976

comes *after* the first name on file 2, the test in line 4080 fails, and we add one to T2 and go through the process again. Eventually, either we come to the last tape file (and the test in line 4070 succeeds), or else we find that the name goes before the first name on file T2+1 (and the test in line 4080 succeeds). In either case, when we exit to line 4110, we know that the member belongs on file T2.

Next, the routine checks to see if the right file is already in memory (line 4120), and if not, we flush out whatever file *is* in memory (using the flush subroutine which begins at statement 7000) and request the proper file (using the tape read subroutine – line 6000). At last we have the right file in memory and we can call the search subroutine (line 5000) to determine where the record goes in the file.

```
4000 REM GET NAME, FIND PROPER FILE AND LOCATION
4010 REM  USED FOR "ADD" AND "DELETE" COMMANDS
4020 PRINT "MEMBER (LAST NAME, FIRST & MIDDLE INITIAL)"
4030 INPUT X$,Y$
4040 LET P$=X$+","+Y$
4050 REM  WHAT FILE DOES "P$" FIT IN?
4060 LET T2=1
4070 IF T2 >= T0 THEN 4110
4080   IF P$ < F$(T2+1) THEN 4110
4090   LET T2=T2+1
4100   GO TO 4070
4110 REM  "P$" GOES ON FILE "T2"  HAVE IT ALREADY?
4120 IF T2=T THEN 4180
4130 REM  DON'T HAVE IT. FLUSH CURRENT TAPE,
4140 REM                REQUEST TAPE "T2"
4150 GOSUB 7000
4160 LET T=T2
4170 GOSUB 6000
4180 REM  WHEW! AT LAST WE CAN SEARCH FOR "P$"
4190 GOSUB 5000
4200 RETURN
```

Binary Search Subroutine

The next subroutine is a key one. It's the subroutine that searches the records in memory for a particular member's name (stored in P$). It's different from last time because now we're storing the records in alphabetical order of the members' names. The main reason we're doing that is to minimize the number of tape operations the user has to do. However, there's an added benefit. Our program will be able to look up records much faster than before. Why's that?

Imagine how horrible it would be if the phone company listed people in their phone directory in the order in which they signed up for phones! My phone book has about 72,000 listings in the white pages. Even if I could look at 5 entries per second, it would take *two hours* to find a number, on the average. (That's assuming I didn't go bananas first.) Of course, the phone company has had the good sense to put the listings in alphabetical order, and we all know how to use that fact to enable us to find a number in a few seconds. Quite a difference.

It's easy to see why having the entries in alphabetical order is such a big deal. If they're not, when I look at an entry and it turns out not to be the right one, I've eliminated just that one possibility. On the other hand, if they *are* in order, and I look at an entry near the middle of the phone book, if it's not the right one, I can eliminate 36,000 entries from further consideration by checking whether the name I want comes before or after the one I just looked at.

It's all very well to imagine looking up numbers in the phone book – now we have to devise a computer program that mimics what we do. The key idea seems to be that as we go along, we keep narrowing down the region of the phone book in which the entry must lie. Let's use two variables, one called L (for Low) which stores an array subscript value which we know to be lower than the position of the name we seek, and one called H (for High) that stores a value which is higher than the subscript of the desired element. Then, each time through the loop, we'll look at the array position midway between L and H. If it's the name we're looking for, we're done. If the name comes earlier than the one we just looked at, we'll adjust H. If it comes later, we adjust L. If L and H squeeze together before we've found the name we want, that means that the name wasn't in the array at all, but that it should be at location H. Since each step of this procedure can eliminate half of the remaining possibilities, it's called a *binary search procedure.* Follow through the flow chart in Fig. 3 with a few examples to get a feeling for how it works.

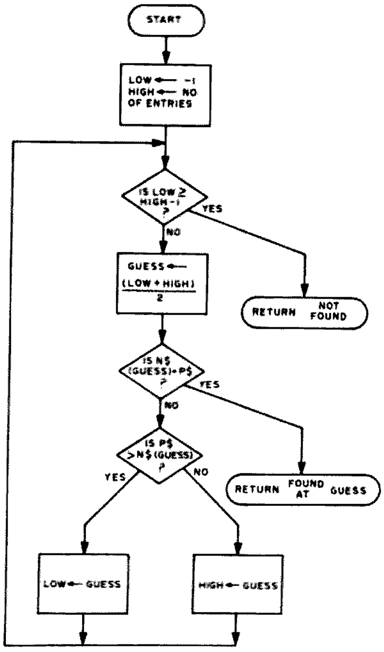


Fig. 3. The binary search procedure.

```
5000 REM  BINARY SEARCH ROUTINE
5010 REM  LOOK FOR MEMBER NAME "P$"

5260 LET F=0
5270 RETURN
```

Read Tape Subroutine

This subroutine is fairly simple, but parts of it depend on the details of your cassette tape interface. I've assumed that on your system, you can "fool" the BASIC interpreter into accepting input values from tape through INPUT statements. On our system, we dig into the interpreter code and change the I/O port specification used by the routine that handles terminal I/O. After the desired values have been read in from the tape, we switch it back so that further INPUTs come from the terminal.

The sequence of statements from 6080 to 6140 may look a little weird unless you recall that every time BASIC comes to a comma in the input, it assumes that's the end of the value, so that, for example, the comma after the member's last name divides the entire member's name into two separate strings.

```
6000 REM  REQUEST AND READ TAPE "T"
6010 REM  DETAILS OF TAPE READ DEPEND ON
6020 REM  SPECIFIC IMPLEMENTATION
6030 PRINT "PLEASE MOUNT TAPE FILE #";T
6040 REM  CALL MACHINE LANGUAGE SUBROUTINE TO
6050 REM  SET UP TAPE READ OPERATION
6060            (call goes here)
6070 FOR I=0 TO G(T)-1
6080   INPUT X$,Y$
6090   LET N$(I)=X$+","+Y$
6100   INPUT A$(I),X$,Y$,Z$
6110   LET B$(I)=X$+","+Y$+","+Z$
6120   INPUT X$,Y$
6130   LET U$(I)=X$+","+Y$
6140   INPUT S$(I),L$(I)
6150   NEXT I
6160 REM  CALL MACHINE LANGUAGE SUBROUTINE TO
6170 REM  STOP TAPE READ OPERATION
6180            (call goes here)
6190 REM  CHECK TO SEE IF THIS REALLY IS TAPE T
6200 IF N$(0)>=F$(T) THEN 6230
6210 PRINT "THIS ISN'T TAPE ";T;" PLEASE CHECK."
6220 GO TO 6030
6230 REM  RESET "TAPE CHANGED" FLAG
6240 LET T1=0
6250 RETURN
```

Flush Current File Subroutine

If the file that's currently in memory hasn't been changed in any way, T1 will equal 0, and we get away with doing nothing (and the user can just rewind the tape and put it away without waiting for the file to be rewritten). If it has been altered, we copy the new version back to cassette tape for storage using the tape write subroutine. "S2" is a parameter which tells the tape write subroutine where to start from in memory. In the "flush" operation, we want to write the entire file, so we set S2=0.

```
7000 REM FLUSH CURRENT TAPE SUBROUTINE
7010 REM IF TAPE "T" HAS BEEN ALTERED
7020 REM THEN REWRITE IT ELSE DONE
7030 IF T1=1 THEN 7050
7040 RETURN
7050 PRINT "PLEASE REWIND AND RESTART
7060 PRINT "THE TAPE (IF T)"
7070 LET T1=0
7080 GOSUB 8000
7090 RETURN
```

Tape Write Subroutine

Like the tape read subroutine, this one is simple conceptually, but depends on your ability to write a machine language program to "fool" the BASIC interpreter. In this case, we want to make the output from a PRINT statement go to the tape machine instead of the terminal. If that's hopelessly messy on your system, you may wind up having to write a machine language routine to handle all the details of memory-to-tape operations. Maybe someday there'll be standards adopted and accepted so we don't have to keep "reinventing the wheel" everytime we want to do I/O!

```
8000 REM TAPE WRITE SUBROUTINE
8010 REM WRITE ALL RECORDS FROM "S2" TO END
8020 REM CALL MACHINE LANGUAGE SUBROUTINE
8030 REM TO SET UP TAPE OUTPUT OPERATION
8040            (call goes here)

8160 RETURN
```

Insert New Record Subroutine

This subroutine is used to carry out the ADD command. It, like the search routine, is more complex than last time because we now want the records to be in alphabetical order. If you look back at the main program, you'll see that this subroutine is called after we're sure the right tape file is in memory, and after we've determined where the new record should go in that file (the binary search routine returns the location in memory cell "I"). In order to keep the records in order, we have to shift some of the records already in the file to make room for the new entry.

The old adage "you don't get something for nothing" applies here. Although keeping the records in order lets us look things up faster, it makes inserting a new record slower. With last month's scheme, we just stuck the new records in the next unused location in the arrays. Now we have to move records (half of them on the average) to make room for the new record. The time difference will be barely noticeable compared to the tremendous savings we make by eliminating tape read operations, so we're still miles ahead with our new scheme.

After adding a new record, we need to change the directory and, since we've just altered the file, we have to make sure that T1 is 1 to reflect that fact (see lines 9200 through 9230).

Before we RETURN, there's one more thing we have to check. What if adding this record has completely filled memory? If so, the next ADD command would cause the file to overflow. Since R1 tells how many records are allowed on a file, we see if we've hit the limit in line 9260. Remember that G(T) tells how many records are on file T. If we have, we initiate an update operation by calling the update subroutine.

```
9000 REM INSERT NEW RECORD AT LOCATION "I"
9010 REM CALL SHIFT SUBROUTINE (D=1 MEANS
9020 REM           SHIFT FROM "I" UPWARDS
9030 LET D=1
9040 GOSUB 11000
9050 REM GET REST OF MEMBER INFO
9060 LET N$(I)=P$
9070 PRINT "STREET ADDRESS"
9080 INPUT A$(I)
9090 PRINT "CITY, STATE ZIP"
9100 INPUT W1$,Y2$,Z$
9110 LET E$(I)=W1$+", "+Y2$+" "+Z$
9120 PRINT "DUES EXPIRATION DATE MONTH YEAR"
9130 INPUT M$,Y$
9140 LET D$(I)=M$+" "+Y$
9150 PRINT "SYSTEM DESCRIPTION"
9160 INPUT S$(I)
9170 PRINT "MAILING LIST (YES OR NO)"
9180 INPUT L$(I)
9190 REM NOW THERE'S ONE MORE RECORD ON THIS FILE
9200 LET G(T)=G(T)+1
9210 LET R0=R0+1
9220 LET F$(T)=N$(0)
9230 LET T1=1
9240 REM IF THIS FILE IS FULL INITIATE
9250 REM AN UPDATE OPERATION
9260 IF G(T)<R1 THEN 9280
9270 GOSUB 12000
9280 RETURN
```

Delete A Record Subroutine

This subroutine carries out the details of the DELETE command. It uses the shift subroutine to shift all records after the one to be deleted, updates the directory, and notes (by making sure that T1 is 1) that the file has been altered.

```
10000 REM DELETE RECORD "I" SUBROUTINE
10010 REM USE SHIFT SUBROUTINE
10020 LET D=-1
10030 GOSUB 11000
10040 LET G(T)=G(T)-1
10050 LET F$(T)=N$(0)
10060 LET T1=1
10070 LET R0=R0-1
10080 RETURN
```

Shift Subroutine

This routine does the shifting required by the insert and delete subroutines. For some reason, it was a real pain in the neck to write. It seems like such a simple thing to do, and now that I've got it working, it looks so reasonable, but ... I wrote it slightly differently at first, only to find that it blew up the first time I did an ADD. The problem was that G(T) is 0 before file T has any records on it, and the way I had written the stupid thing, it tried to access array location -1. I'm sure it demonstrates some Grand Principle about programming, but which one I don't know. Probably some variant of Murphy's Law.

```
11000 REM SHIFT SUBROUTINE
11010 REM SHIFT ALL RECORDS BETWEEN "I"
11020 REM AND END. DIRECTION DEPENDS ON "D"
11030 IF D<0 THEN 11080
11040 REM INSERTING GO FROM END DOWN TO "I"
11050    LET S0=G(T)
11060    LET F0=I
11070    GO TO 11110
11080 REM DELETING GO FROM "I" UP TO END
11090    LET S0=I
11100    LET F0=G(T)-1
11110 REM DO IT
11120 IF S0=F0 THEN 11210
11130    LET N$(S0)=N$(S0-D)
11140    LET A$(S0)=A$(S0-D)
11150    LET E$(S0)=E$(S0-D)
11160    LET D$(S0)=D$(S0-D)
11170    LET S$(S0)=S$(S0-D)
11180    LET L$(S0)=L$(S0-D)
11190    LET S0=S0-D
11200    GO TO 11120
11210 RETURN
```

Update Subroutine

When repeated ADDs have filled up a file, we have to do something about it. The most reasonable thing to do seems to split that file in half and make two tape files out of it. Why does that seem reasonable? Another option would be to add a new tape file at the end of the library, and then spread the records from all the files out evenly. Since that would mean a tremendous number of tape reads and writes if the library was big, I ruled it out (we don't want people sitting around muttering subversive things like "Why don't we up the club dues and get a disk?"). After I had ruled out the second option, I came up with another reason for ruling it out: If a particular file has overflowed, it might be because a lot of club members have names in the same part of the alphabet, so it makes more sense to make more room right around that file than to make a little more room throughout the alphabet.

Since the update yields two tape files where there was one before, and since the tape files themselves have to be kept in alphabetical order for the directory scheme to work right, the user has to

Debugging: Some Tips

The first principle of debugging may seem obvious, but for some reason it gets violated all the time. *You have to know what's supposed to be going on before you can tell what's wrong.* In practical terms, that means that you should have your flow charts, plans, and notes by your side (and you should *use* them) as you try to figure out why the program's responses are wacky, why you're getting that error message, why you feel nervous.

BASIC provides some nice features that aid debugging. It's easy to toss STOP statements at suspect places, and when the program stops there, to use the system in the "console mode" to investigate what's happening.

For example, when I ran into trouble with the shift routine, I typed

```
11125 STOP
```

and ran the program again. When it stopped at 11125, I typed

```
PRINT S0, F0
```

and the system responded

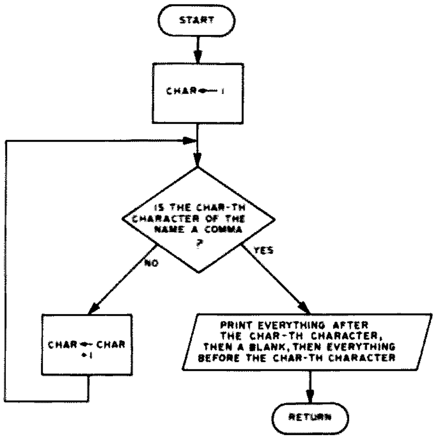
```
-1        0
```

That told me why I was getting the "subscript out of range" error message, but why was S0 starting off at -1?

The important thing at this point, and the thing that takes some discipline, is to resist the temptation to slap in the first fix you can think of that will cure the immediate symptom. You'll be much better off if you take your time, prowl around checking values, figuring out what the real problem is. In this case, it turned out that my whole strategy for shifting was wrong. If I had just changed the statement that set S0 to its initial value, the program would have failed in other situations.

Some Possible Improvements

One added feature that would be worthwhile would be for the LIST command to convert the member names to the "first middle last" form before printing out the mailing labels. Most people would probably rather have their mail addressed to them that way. Your version of BASIC should have built-in string manipulation functions which will make it easy to code this flow chart:



Another problem that could use some work is that the program is totally unforgiving about misspellings. You might find it nicer to have the program check just the first letter of the commands, so that misspellings like the one in the sample run (DELTE for DELETE) wouldn't make any difference. A similar but bigger problem is that if you don't abbreviate a member's name the same way on different occasions, the program will treat each different spelling as a different member. One solution would be to write a subroutine which can tell if two names are "close." It could decide that two names were "close" if the last names were the same and the first names have a lot of letters in common. Then if the user types a name that the program can't find, the program can look for names that are "close" to the one the user wants. If the program manages to find such a name, it should then ask the user if the two names actually refer to the same person.

One last thing: If you're tight on memory, you'll probably benefit by redoing the part of the program that decides when to do an update. If you have the program count the number of *characters* on each file instead of just the number of records, you'll be able to squeeze every last byte out of your memory. Hopefully your version of BASIC has a built-in function that computes the length of a string (it's called LEN in Altair BASIC), which will help greatly.

renumber all the tapes after the one being updated. That's a possible source of error, so anyone who is going to have access to the system should be warned about it. If the tape files *do* happen to get out of order, the tape read subroutine will catch the error (see lines 6190 through 6220), but it might take a number of laborious tape reads to get things working again.

The subroutine should be pretty easy to follow. It copies the second half of the file in memory to the new tape and then updates the directory appropriately. It leaves the rest of the old file in memory, and since it's still file number T, nothing has to be done except to record its new (shorter) length in the directory (line 12240).

```
12000 REM  UPDATE SUBROUTINE
12010 REM  MOVE SECOND HALF OF CURRENT FILE
12020 REM  TO A NEW TAPE, PATCH UP DIRECTORY
12030 PRINT "THIS FILE IS ABOUT TO OVERFLOW
12040 PRINT "GOING TO BE A BIT OF WORK HERE
```

```
12050 PRINT "FIRST REWIND CURRENT TAPE. IT WILL
12060 PRINT "STILL BE CALLED TAPE FILE  ";T
12070 LET T0=T0+1
12080 IF T+1>T0 THEN 12120
12090 PRINT "UNFORTUNATELY, YOU MUST RENUMBER
12100 PRINT "OLD FILES WITH NUMBERS ABOVE ";T
12110 PRINT "TO MAKE ROOM FOR A NEW FILE."
12120 PRINT "NOW LOAD A FRESH TAPE, CALL IT #";T+1
12130 LET [illegible]
12140 GOSUB [illegible]
12150 PRINT "NOW PLEASE TOSS TAPE ";T;" BACK"
12160 PRINT "ON THE MACHINE, BUT DON'T RUN IT
12170 REM  SHIFT ENTRIES IN DIRECTORY TO MAKE ROOM
12180 FOR J=T0-1 TO T+1 STEP -1
12190    LET [illegible]
12200    LET [illegible]
12210    NEXT J
12220 LET [illegible]
12230 LET [illegible]
12240 LET [illegible]
12250 PRINT [illegible]
12260 RETURN
12270 END
```

Using The System

To use the record-keeping program on your system, you need to copy the statements in the program, fill in the calls to machine language subroutines to do the cassette tape operations, find a good, safe place to store the cassette tapes which hold the directory and files, and let 'er rip! Here's a sample run showing some of the features (I've underlined the parts I entered).

```
RUN
IS THIS THE FIRST USE OF THIS SYSTEM? NO
PLEASE MOUNT AND RUN THE DIRECTORY TAPE
(I did as directed.)
THANKS. YOU CAN REMOVE DIRECTORY TAPE
WANT A SUMMARY OF COMMANDS? NO
(Surely I know them by now, I said.)
COMMAND? ADD
MEMBER (LAST NAME, FIRST & MIDDLE INITIAL)
? PINSKY, PAUL D
PLEASE MOUNT TAPE FILE #3
(As I did, I wondered if I should have added
    AND RUN IT to that message.)
ADDING A NEW RECORD FOR PINSKY, PAUL D
STREET ADDRESS
? 12300 HAMILTON AVE
CITY, STATE, ZIP
? PALO ALTO, CA 94301
DUES EXPIRATION DATE (MONTH, YEAR)
? MARCH, 1977
SYSTEM DESCRIPTION
? [illegible]
MAILING LIST (YES OR NO)
? YES
COMMAND? ADD
MEMBER (LAST NAME, FIRST & MIDDLE INITIAL)
? SMITH, ALVY RAY
ADDING A NEW RECORD FOR SMITH, ALVY RAY
STREET ADDRESS
? 10 GARBONZO LN
CITY, STATE, ZIP
? LOS GATOS, CA 94030
DUES EXPIRATION DATE (MONTH, YEAR)
? MARCH, 1980
SYSTEM DESCRIPTION
? ALTAIR 8800A
MAILING LIST (YES OR NO)
? YES
COMMAND? DELTE
SORRY, BUT DELTE ISN'T A COMMAND
([illegible])
WANT A SUMMARY OF COMMANDS? NO
COMMAND? DELETE
MEMBER (LAST NAME, FIRST & MIDDLE INITIAL)
? CALDWELL, ERNIE
PLEASE REWIND AND RESTART
THE TAPE (FD)
(Right. The first part of the alphabet is on tape 1
    [illegible] ADDs, so
    tape 3 has to be rewritten.)
PLEASE MOUNT TAPE FILE #1

CALDWELL, ERNIE
2203 POWELL ST
SANTA CRUZ, CA 95063
JAN, 1976
NONE
YES
STILL WANT TO DELETE IT? YES
([illegible])
COMMAND? END
PLEASE REWIND AND RESTART
THE TAPE (FD)
([illegible]
    [illegible])
PLEASE MOUNT DIRECTORY TAPE
([illegible])
THERE ARE 4 FILES IN THE LIBRARY
CONTAINING 347 RECORDS
SEE YOU AGAIN
```

The only things that aren't demonstrated in the sample run are the mailing LIST option, which prints names and addresses (we cut them out of the listing and use them as address labels), and the update operation, which happens whenever a file gets full.

So that's the record-keeping program. In one sense, it's finished – it works, it does what I wanted it to, it's useful. In another sense, it'll never be finished – as it gets used, inconvenient features come to light; occasionally other ways to organize it enter my mind. I guess the ultimate record-keeping program would be one that did absolutely everything all by itself, from reading the morning mail, to cashing checks, to sending notices to people who are behind in their dues, to keeping me company when nobody is around. That one will have to wait a while.

As The Smoke Clears . . .

Well. We've covered an incredible amount of material in these three articles. Possibly too much. Certainly too much to absorb completely if you really were starting from scratch in Part I. But even if it doesn't all fit together for you yet, I hope the feeling of what it's like to program got across. The feeling that when you actually start doing something, you're in for a struggle at times, some ups and downs. The feeling that to create a finished product you have to keep refining, testing, and revising your plans. No one has ever written even a medium-sized program by just sitting down at the terminal and pounding out lines of BASIC. If that was all there was to it, it wouldn't even be much fun. What I really like about programming is that it involves many apsects of life itself: dreaming, planning, testing, bringing your dreams down to the hard reality of what the machine can do, getting the bugs out, refining your plans, finally seeing your program run, using it, and then starting to dream about the next grand scheme. It's great! ■

Getting By the Friden-8800 Communications Gap

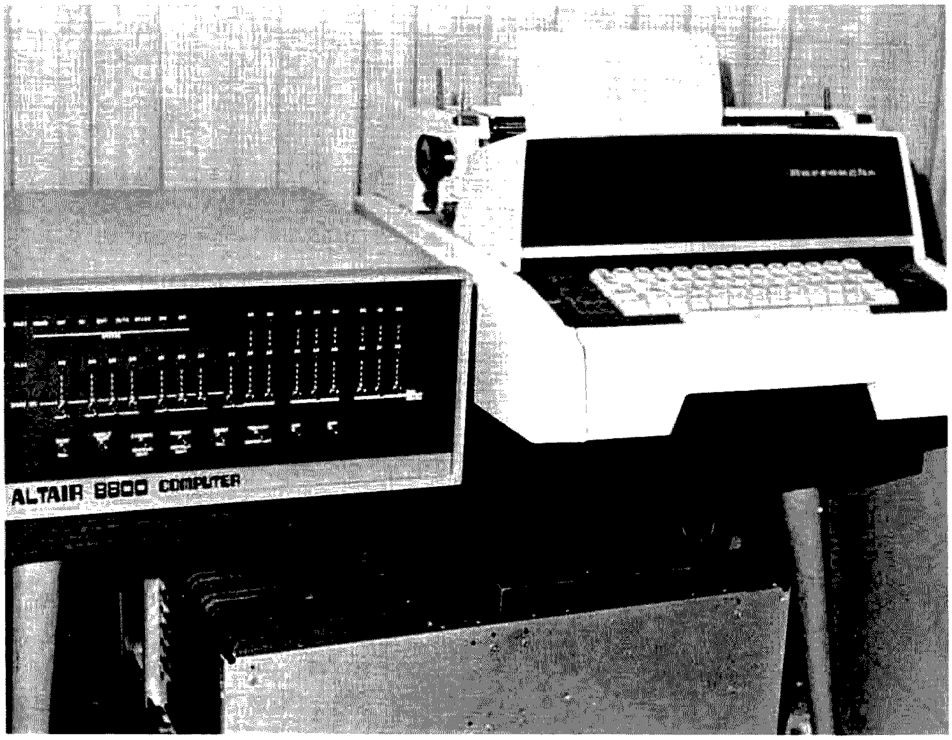
-- interface made easy

Recently, a number of Friden keyboard-printers and associated controllers have appeared on the surplus market. This article is concerned with the TM 20K714 keyboard-printer and its companion TM 20K715 controller, which, in combination, formed the heart of the Burroughs 9350-2 Communications Terminal. While these are certainly impressive looking units, hobbyists have been experiencing difficulty in getting them "on-line" with their home computer systems. This article describes the hardware modifications and the software which were implemented to overcome the communications gap which existed between my 8800 and the asocial Friden.

Hardware

Hardware modifications to the 8800 and the Friden's control unit are relatively straightforward.

Photo by Doug Wood



The Altair/Friden system. The 8800 is sitting next to the Friden TM 20K714 keyboard-printer. The TM 20K715 controller (without its cover) is visible under the table.

The input and output of the controller is RS-232-B compatible. In this configuration, the resting, mark, or logic 1 condition is more positive than +3 volts and the space or logic 0 condition is more negative than -3 volts. The EIA serial interfaces, which are being used by most hobbyists, conform to RS-232-C specs. This configuration defines the logic 1 condition as more negative than -3 volts and the logic 0 condition as more positive than +3 volts. Consequently, for 150 baud serial transmission to and from the Friden it is necessary to invert the polarity of the transmitted and received data signals.

Due to the fact that I have a Processor Technology 3P+S interface, the parts necessary to invert the signals already existed on the board (see Fig. 1). Pin 25 (the "Tx Out" of the UART) was connected as usual to the appropriate gate of IC5, which provides the RS-232-C output. The output of this gate was connected back to the input of a second gate of IC5. The output of this second gate now provided the appropriate polarity signal for transmission to the terminal, i.e., the output signal now conformed to RS-232-B specs as a result of

the additional inversion provided by the second gate. In order to receive data from the Friden, two gates of IC10 on the 3P+S were similarly cascaded. The additional inversion provided by the first gate makes the Friden's RS-232-B transmitted signal appear as RS-232-C to the second gate. The output of this second gate is connected to pin 20, the "Rcv In" of the UART.

For those of you who have other I/O interfaces, all that is required is to connect an inverter (such as a TTL NOR gate) between the data pins of the UART and whatever circuitry (be it transistor or IC) which presently boosts the I/O signals to the RS-232-C level. By inserting the inverters between the UART and the existing circuitry, you will invert the data signals and still maintain the RS-232 drive levels. Such would not be the case if the TTL inverters were external to the existing circuitry.

The only other hardware modification required is at the 25-pin connector of the Friden's controller. Tie pin 5 (Clear to Send Line) to pin 20 (Terminal Ready Line). With pin 5 positive and the ON-LINE switch activated, the orange ON-LINE light will be illuminated, confirming the status of the Friden. The Friden is now capable of transmitting to, and receiving from, the 8800.

To help clarify the logic of the software routines which I developed, it is beneficial to examine the terminal's transmission and reception procedures.

Keyboard Transmission Procedure

To transmit from the keyboard, assuming the terminal is operating properly "on-line," the operator presses the TRANSMIT key. This initiates the transmit mode, lights the TRANSMIT and SEND lamps, unlocks the keyboard, and causes the transmission of an STX character to occur. The operator may then enter a block of data, terminating it by pressing the ETB or ETX key. (Data are provided to the line as keyed, and also stored in the terminal's buffer for possible later retransmission.) For simplicity's sake, we will not make use of this retransmission feature. Following transmission of the ETB or ETX character, the SEND lamp then turns off and the terminal generates a Longitudinal Redundancy Check (LRC) character, which it also sends down the line to the computer. The terminal then waits for an ACK status character from the computer. If this is received when the transmission was terminated by an ETB, the terminal is cleared, the keyboard unlocks, and the SEND lamp comes on. The last block of a transmission should be terminated by an ETX character. Now, following reception of an ACK character by the terminal, the TRANSMIT lamp goes out and the terminal returns to the idle mode.

A conventional input routine will readily accept data from the Friden. Since instances of these are common, I will not get into a description of one here. However, a few suggestions concerning the routine are in order. You may choose to have the routine ignore the STX character, since it is not a piece of valid data with reference to your text. However, the routine should recognize the ETB/ETX characters as flags, and upon their detection send an ACK to the Friden. Your input routine should also ignore the terminal generated LRC character; like the STX, it is not relevant to the actual text being transmitted. You could use a routine, similar to the one presented later, which will use the LRC for detection of transmitted errors, but it is not necessary for the input routine. (As you will soon see, the LRC character plays a major role in outputting data to the Friden.) Note that it is important (necessary) to reply to transmissions from the Friden by sending back the ACK character; otherwise, the keyboard will remain locked up and the TIME-OUT and ERROR lamps will come on. Keep in mind that the Friden's buffer has a maximum capacity of 150 characters before the OVERFLOW light comes on.

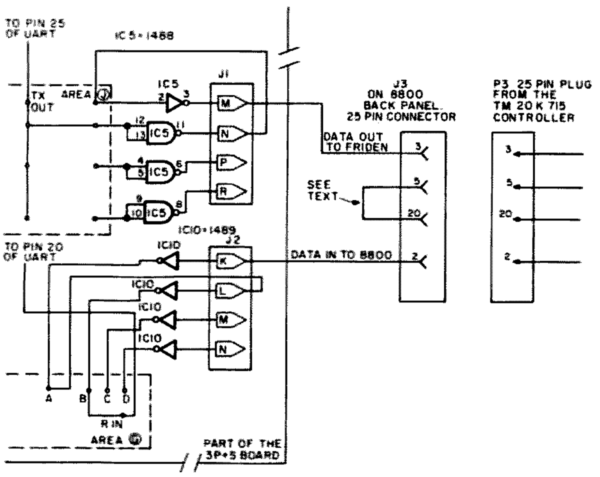


Fig. 1. The interconnection between the Friden's TM 20K715 controller and the Processor Technology 3P+S interface. Note the cascading of the top two gates of IC5 and IC10, to provide the necessary inversion.

Printer Reception Procedure

When the terminal is neither transmitting nor actively receiving, it is in an idle mode. Message reception begins with the detection of an STX character from the computer. As characters are received, they are placed in the Friden's buffer. Upon reception of an ETB/ETX character, the terminal generates an LRC character and looks for an identical LRC character to be sent down by the computer. If no LRC errors have been detected, the terminal transmits an ACK character to the computer and commences to print the contents of its (the terminal's) buffer. The terminal resets the green RECEIVE lamp and returns to the idle mode following reception of the ETX character.

The software presented below causes the 8800 to simulate the transmit conditions which existed at the Burroughs B3501 (the Friden's host computer). As can be seen, the requirements necessary to make the Friden accept data from the 8800 are much more stringent than the conditions required to make the Friden "talk" to the 8800.

The Software

For explanatory purposes, the program is divided into two main routines: BUFFIN and PRINT. BUFFIN is called up by the output routine of my MONITOR program. (Any general output routine can be used to call BUFFIN.) In my system, as the MONITOR outputs data the characters are displayed on a CRT display and stored in a buffer area in the 8800's memory, for eventual transfer to the buffer of the Friden. When a CR character is detected, BUFFIN calls up the PRINT routine. PRINT is responsible for the actual transfer of data from the buffer in the 8800 to the Friden's buffer, and for the generation and transfer of the "handshake" characters described previously. BUFFIN and PRINT will not interfere with the outputting of data to the

CRT display, other than causing a 4 to 7 second delay at the end of a CR-terminated line. This time is consumed by the 8800 transferring data from its buffer to the Friden's buffer, and for the detection of the Friden-generated ACK flag.

Use has been made of memory storage and the stack, to save the status of some of the registers which are redefined when BUFFIN and PRINT are called. The data are assumed to reside in register B prior to calling BUFFIN. The program, as presented, resides in the top 1K of my 9K memory; when you relocate it, pay close attention to the memory references. Nothing can make you wish you had taken up another hobby faster than having to track down an errant memory reference.

As you study the program,

BUFFIN	Pg. 041-100	345	Push H	Save main mem pointer
	101	041	LXI H	Initialize buffer pointer

it will become apparent that the main calling routine could call PRINT directly, circumventing BUFFIN. You may elect to do so. However, if you use the Friden to get hard copy while you are getting soft copy on a CRT, you may have problems. Some programs, such as those for games, may only output half a line; they may then wait for an operator response before finishing the line and generating the CR character. This is OK on a CRT display, where printout is instantaneous (well, almost instantaneous) and not being timed. But remember that the Friden has a 25 second timer which starts with the reception of the STX character. If the ETB/ETX and LRC characters are not received in the 25 second interval, a TIME-OUT-ERROR condition will be displayed. Consequently, the Friden's buffer will be cleared and no printout will be obtained. Use of BUFFIN ensures the existence of a CR character in the 8800's buffer, and the generation of the all-important ETX and LRC characters by PRINT, within the timed interval. Alas, this is one shortcoming of this configuration of the Friden; it isn't particularly suited to interactive work.

Conclusion

Well, there it is. It isn't the most efficient program, memory-wise. (I don't profess to be a programmer.) But it does work, and the Friden produces a hard copy with a style all its own. Before configuring it to your system, be certain that you understand "everything" in the program. I wouldn't want to see anybody have to put the days (and sleepless nights) into this project which I put into it. Actually, it was fun, but it had its moments.

Good luck with it. If you have any difficulties, send an SASE and I will try to help you out. Keep on computing! ■

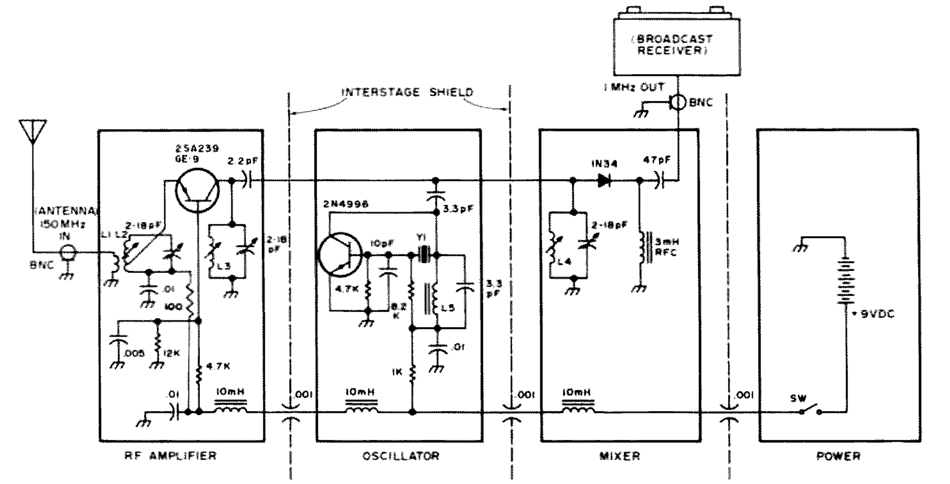

Fig. 1. Two meter to broadcast band converter. L1: 2 turn link on low end of L2. L2: 4 turns #20 on 7 mm slug-tuned form spaced to 5 mm; tap at 1½ turns from low end. New Improved Repeater Monitor

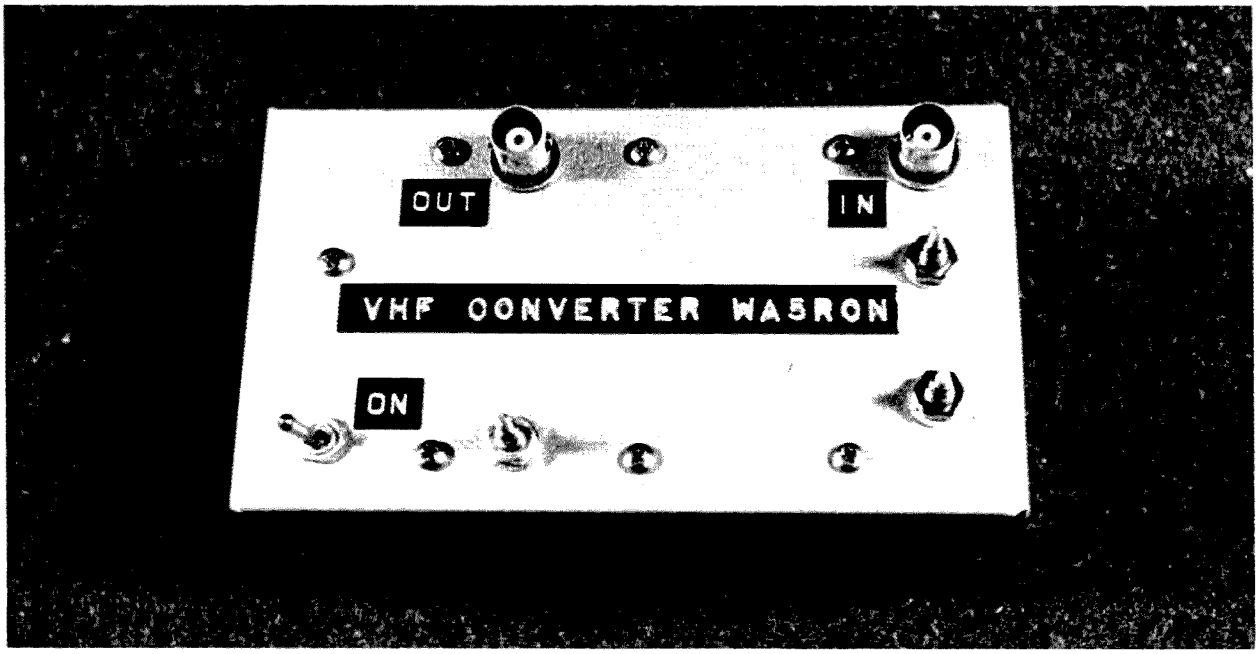
-- 2 transistors

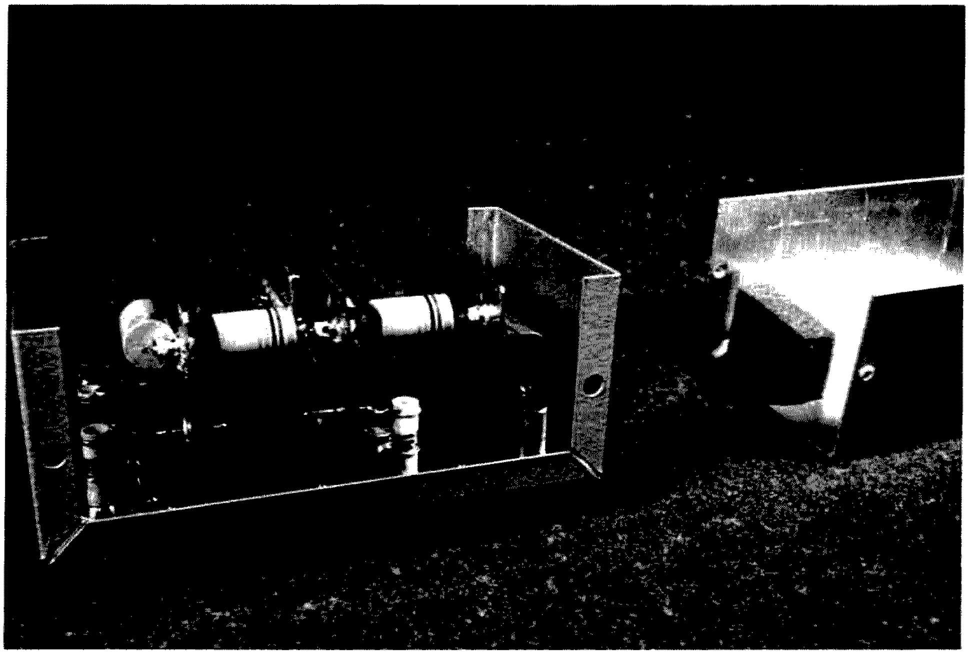
Another converter? Well, maybe there have been an awful lot of converter designs published in these pages, but take a careful look at this one before you say you don't need a converter. The unit described here is designed to let you tune a 1



MHz band on two meters using your automobile radio. Even if you already have VHF gear in your car, chances are that you can only receive at a few crystal frequencies, and you would appreciate being able to tune the band to see what is going on. You could also use this converter in a rented car, your wife's car, or for one way communication when traveling with other (non-radio equipped) vehicles on the road. I suppose that you could even build it for the police frequencies or other VHF services.

I thought of building this converter one day when I noticed the push-button AM radio mounted nicely in the instrument panel of my automobile, and realized that it had not been turned on for at least two years (if you reside in Texas but don't like cow music, the AM broadcast band has little to offer). I thought how nice it would be if the coverage of that receiver were in one of the ham bands instead of 300 meters, and I decided right there to build a converter.

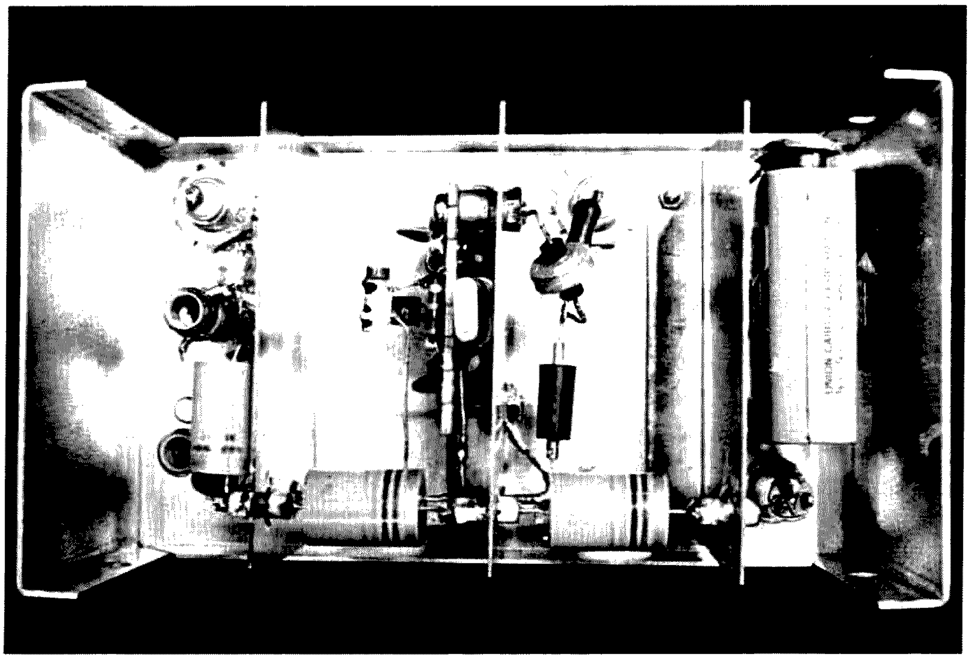
I found a simple converter design in an issue of *73*[1], and quickly built one up as in the article. The unit worked, a two meter QSO on one of the repeaters was heard, but it was competing (and losing) with all the 50 kW cow stations that were there, hardly attenuated at all by the converter in the antenna line. It appeared to me that any converter I built to work into the broadcast band as an i-f would have to have considerable isolation between input and output, and that at least one stage of rf amplification ahead of the converter was certainly desirable. The design that evolved is noteworthy in its attention to shielding, compartmentalization, and rf blocking along the power lead, considerations that are necessary in preventing the bleed-through of broadcast stations. Fortunately, automobile radios are already well shielded and bypassed, and they make sensitive i-f receivers with plenty of audio output.



Converter interior is divided by copper shields into four compartments. Block of foam-rubber glued to case half keeps the battery in its clip on bumpy roads.

A 5.5 x 7.5 x 13.5 cm Bud minibox was divided into four compartments by shields cut from sheet copper (hobby or arts and crafts shop). A .001 uF feedthrough capacitor is mounted in each of these shields to pass (and bypass) the power lead, and two of the shields are also fitted with an insulated feedthrough (a grommet will do) for rf. The four compartments contain preamp, oscillator, mixer, and power supply. This last is a 9 volt battery that will run for a long time at 25 mA drain, providing you remember to turn the unit off when not in use.

The preamp is a non-FET design found in Japanese VHF receivers, with a link-coupled input circuit added to discourage the beastly broadcast band from getting deep into the converter. If you don't have a 2SA239 lying around, then any of the



Converter sections are (left to right): 1 — Input and rf amplifier stage, 2 — Crystal controlled oscillator, 3 — Mixer stage and output, 4 — Battery and switch.

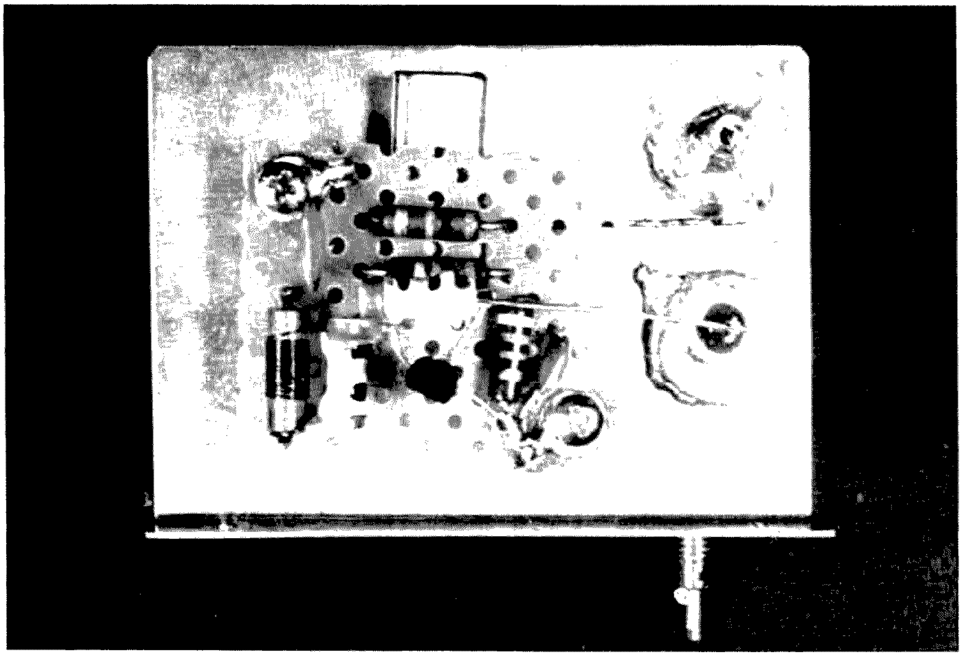
Shielding and separation of input and output sections, plus elaborate bypassing of low frequency signals on both rf and power leads is necessary to keep powerful broadcast stations from shoving their interference through the converter.

"equivalent" transistors they sell nowadays in the wholesale stores should work. I tried a GE-9 and it did just fine. Component leads must be very short or they will add inductance in series with the coils, which are quite small. Ground points can be soldered directly to the copper shield.

The oscillator was wired together on a small piece of vectorboard, held by machine screws and short standoffs to the copper shield. The oscillator stage was put between amplifier and mixer to maximize the physical separation between input and output. A third overtone crystal in the 48-49 MHz range is employed, giving a third harmonic at two meters that is used by the mixer stage. Choose a crystal frequency such that when multiplied by three, the resultant frequency is 600 kHz below the bottom of the range you would like to tune. For example, if you wish to tune the popular FM frequencies between 146 and 147, a crystal near 48.4667 could be selected. The third harmonic would be 145.4, putting 146 at the 600 kHz mark, and 147 at 1600. This should be fine for locating repeaters in unknown towns as you travel about, or just keeping tabs on local FM activity. If you would like to preserve the usefulness of the original dial calibrations, then you need a crystal cut for 48.6667 (146.0). This will put 146.55 MHz at the little "55" on the dial, and 147.6 will come in at "160" or "16" or whatever you have at the top end. When you order a crystal, include a drawing of the oscillator schematic, and tell the manufacturer what third harmonic frequency you want to get, as well as the 48 MHz third overtone frequency.

You will note that the tuned circuits in this converter have both variable capacitors and slug-tuned coils. This allows one to roughly peak the circuits using the capacitors with the box open, and then fine tune all stages after the unit is closed up and mounted in the vehicle. Cut a length of antenna cable to go between converter and radio, with a Motorola plug on one end and a BNC on the other. The car's telescoping whip antenna will work just fine when pushed down to quarter wavelength, and if the feed line is replaced with RG-58 or RG-59. The original automobile antenna cable seems to be some sort of cheapo shielded stuff with a kinky wire for a center conductor. I suspect that it was not intended for VHF, and certainly not very good for transmitting.

Many new cars seem to come with a solid steel whip. This could be used as is, but cutting it to quarter wavelength will improve VHF



The oscillator board mounted on one side of a shield. Crystal socket and miniature crystal are the only components on the backside of the board. Power feedthrough capacitor is at upper right and insulated feedthrough for the rf line is below. Mixer stage (part of coil visible at bottom) is on the reverse side of shield.

reception and broadcast image rejection. I can't recommend those imbedded-in-the-windshield type antennas at all. This novelty was foisted on the car buyer at about the same time as the something-else-to-malfunction hideaway headlight. If you got stuck with one (or both) of these, you might as well punch a hole and mount a decent two meter antenna. After all, you are a ham, aren't you?

Plug the converter in and tune up the circuits on a signal somewhere near the middle of the band. Look for the antenna trimmer capacitor on the broadcast radio and tune for maximum signal reception. This capacitor may be found near the antenna input connector, or behind a hole above the tuning shaft that can be reached by pulling a knob (instead of pulling the whole radio). This adjustment does make a difference.

My little converter should give you good reception on two meters of both AM and FM stations. The ability of the automobile radio to slope-detect FM depends upon the sharpness of its i-f tuning. I found that I was able to improve the tuning and tracking across the band of both i-f and rf stages within the receiver by tweaking on the slugs. Getting the radio out and back into most modern automobiles is made easier by turning the vehicle upside down and moving the firewall forward a few feet.

You might even go so far as to cut into the original AM board and add one of the FM limiter and discriminator integrated circuits. I think that you will find, however, that FM reception is quite acceptable without any modification to the broadcast receiver. ■

Put Snap in Your SSTV Pictures

-- using a $20 freq standard

E. Sommerfield W2FJT
49 Spring Road
Poughkeepsie NY 12601

Frequency measurement has always been an expensive problem for the radio amateur; the least expensive frequency counter costs about $150. Frequency measurement by counting is not the only method of measurement, however. Another less expensive, and equally accurate, alternative for specific applications is called frequency comparison. This article will describe a crystal calibrator/comparator for SSTV that will permit adjustment of various SSTV frequencies to within 1 Hz for as little as $20. The calibrator can either be built into the Robot Research 80A camera, or implemented as a self-contained unit for an additional $10.

Overview

The basic requirement in any frequency comparison system is an accurate frequency source. One such source is a crystal oscillator in the 1200 Hz to 2300 Hz range. Crystals in this frequency range are somewhat difficult to fabricate; however, crystals in the 256th multiple of this range (300 kHz – 600 kHz) are easily obtained. All that is required is a division by 256, and a frequency comparator.

In both the 80A and self-contained versions (Fig. 1), a crystal controlled square wave generator at 307,200 Hz (1200 Hz x 256) is fed into a 256 divider chain and emerges as 1200 Hz. This 1200 Hz signal is then compared to the 1200 Hz SSTV video. The resultant "beat note" is displayed on an LED (Light Emitting Diode).

In the 80A version, Fig. 1(b), the divider chain in the NORMAL mode is used to convert the 15 Hz horizontal input to a 1/8 Hz (8 second) vertical signal by dividing by 128; the last counting position is not used. In the COMPARE mode, the input to the 256 divider chain is changed to 307,200 Hz and the output at 1200 Hz is taken from the last position. The same "beat note" detector is used. If operation at 2300 Hz is desired, a crystal frequency of 588,800 Hz would be required. Since crystals in this frequency range cost $37.50, a crystal at 1/2 the frequency, 294,400 Hz, costing $13.50 is used, and the output is taken at the divide by 128, the next to the last, divider position.

CIRCUIT DESCRIPTION

The oscillator and comparator are both contained in an RCA CA-3046 5 transistor DIP module.

Oscillator

The oscillator is a standard 2 transistor free-running

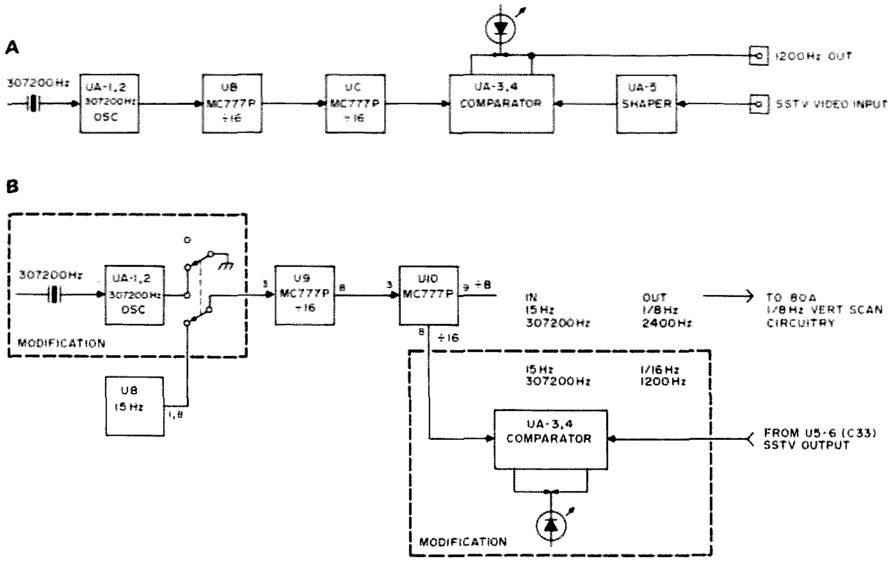

Fig. 1. Overview of crystal clear 1200 Hz.

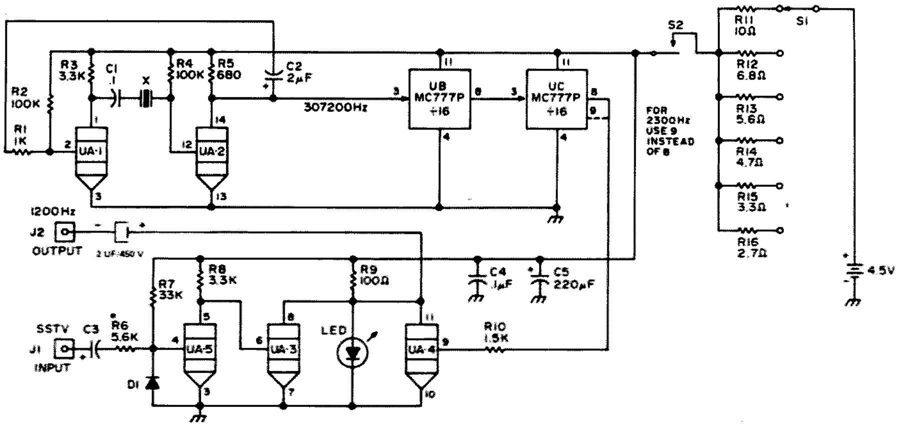

*Fig. 2. Self-contained crystal clear 1200 Hz. U1 — RCA CA3046; U2, U3 — Motorola MC777P; S1 — Archer 2751386; LED — Archer 276-041; S2 — Calectro E2-140; R1-R10 — ¼ W 10%; R11-R16 — ½ W 10%; D1 — Archer 276-612 or 276-114; chassis box — Calectro H4-742; battery holders — 1 cell, Calectro D3062; 2 cell, Calectro D3063. Calectro = Lafayette, Archer = Radio Shack. *R6 was designed for an 80A output greater than 2 V p-p and a low output source impedance. X — see Crystal Specifications.*

multivibrator in which one of the RC networks has been replaced by a crystal. The free-running frequency, originally controlled by the RC networks, is now controlled by a .01% tolerance crystal. The maximum crystal error is 30 Hz at 307,200 Hz. When the frequency is divided by 256, the error, which is also divided by 256, becomes .12 Hz; this is far more accurate than any SSTV requirements. The output of the oscillator is a square wave which when loaded is about 1.0 volts to 1.7 volts at 307,200 Hz. The oscillator was designed to have a minimum loading effect on the +3.6 volt regulated supply (80A). The 80A +3.6 volt supply already has about a 200 mA load, and the regulator transistor is "hot" to the touch.

Comparator

The comparator is composed of 2 inverters with a common collector load resistor and shunting LED. The LED has a minimum voltage threshold of about +1.2 volts. Current will flow in the LED only when BOTH transistors UA-3 and UA-4 are off. The amount of time that both are off, and in turn the LED is illuminated, depends upon the frequency relationship of the 1200 Hz crystal controlled reference frequency and the SSTV input frequency. As the two signals "beat" together, the LED will "flicker" at the rate of the difference frequency. Since the two signals will rarely lock together at the same frequency, there will always be some flicker. The comparator output when no SSTV video is inputted consists of a 1200 Hz square wave of about 1 volt p-p. This signal, with a very low source impedance, is ac coupled to the output jack, J2, and can be used as a 1200 Hz signal generator.

Divider Chain (Self-Contained Only)

The divider chain in the self-contained version is identical to the one used in the 80A, and consists of two Motorola MC777P binary counters connected in tandem. Since the divider chain counters are unloaded, I found that the most reliable operation was obtained at about +3.2 volts.

Switch (80A only) Fig. 3

Many methods were analyzed in order to find a method of injecting the 307,200 Hz signal into the 80A divider chain without disturbing the land pattern. The only solution found, however, was to "break" the land pattern on the back of the component board as shown in Fig. 4. Leads to the modification can be run from either the land pattern on the back, or touch soldered from the pins of the DIP modules on the front, depending on the skill of the user.

The switch, S1, provides the means by which the 307,200 Hz signal is injected into the divider chain.

Power Supply (Self-Contained Only)

The divider chain, unloaded in this application, works optimally at about +3.2 volts ± .2 volts. The load current is about 150 mA. A power supply could have been constructed for about

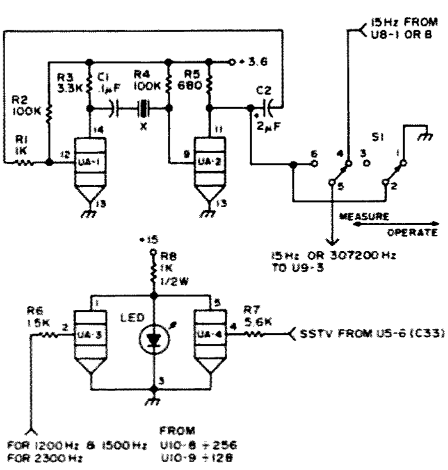

Fig. 3. 80A modification. All resistors except R8 can be as low as ¼ Watt 10%. U1 — RCA CA3046; LED — Archer 276-041; S1 — Calectro E2-105; C2 — Calectro A1-125; X — see Crystal Specifications; term strip — Calectro F3214. Calectro = Lafayette, Archer = Radio Shack.

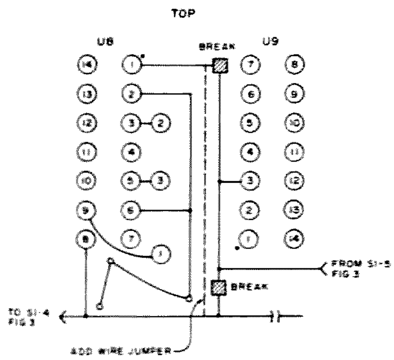

Fig. 4. 80A land pattern modification. Wiring (back) side of board.

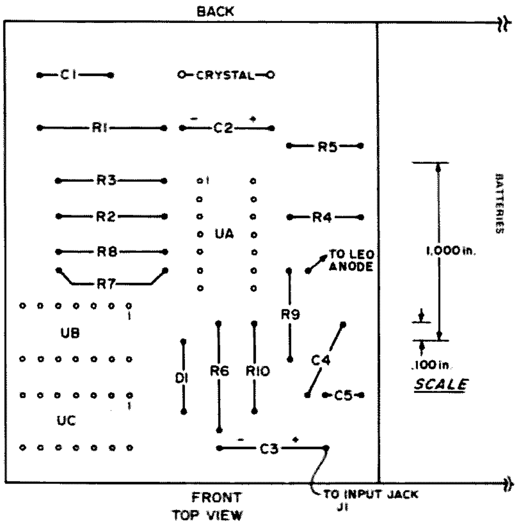

Fig. 5. Self-contained perfboard component locations.

$10, but the intermittent use of this unit pointed to the use of a battery supply for about $1. In order to obtain maximum use of the battery as its voltage decreases with age and use, a variable resistor, or as in my case, a switch with resistors (Fig. 2), was used to permit adjustment of the supply voltage. Too high a supply voltage causes a 2400 Hz output; too low a voltage results in no output. The correct voltage is easily obtained by first connecting earphones to the 1200 Hz output jack, J2, and then, starting at the maximum resistance, slowly reducing the resistance until the 1200 Hz signal is heard.

CONSTRUCTION

Self-Contained

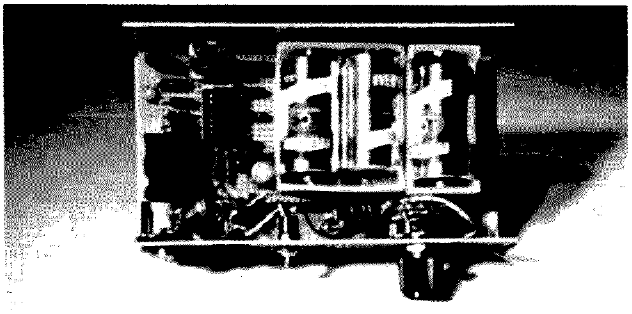
The self-contained version layout is shown in Fig. 5 and the photograph. It is constructed on a 2.5" x 6" piece of .100 x .100 inch perfboard (Archer – Radio Shack – #276-1394). R11-R16 are mounted on the chassis, supported between S1 and S2.

80A

The 80A layout requires more effort, but it has the advantage of a more built-in feature. Fig. 6 shows the location of the components. The crystal socket, switch S1, and the module DIP socket were epoxied onto the component board. The terminal strip was anchored using the screw that attaches the component board to the camera chassis.

Operation

Adjust the 80A output control, R50, to 2/3 full scale (self-contained only). In order to measure only 1200 Hz, the SSTV voltage controlled oscillator (VCO) must first be forced into a 1200 Hz only mode. This can be done in the 80A by shorting the collector of Q8 to the emitter of Q8, by grounding the junction of resistors R34, R35 and R134. This method will result in a sync frequency of about 1190 Hz. The reason for the 10 Hz difference is that the normal "on" condition for Q8 is not a shorted collector to emitter, but rather a .1 volt collector to emitter. Since the more positive the collector of Q8 is from -15 volts, the lower the frequency, 0.0 volts = 1190 Hz, whereas 0.1 volts = 1200 Hz.



After the 1200 Hz only condition is satisfied, adjust R42, SYNC, so that the LED just barely flickers. This setting will result in about 1210 Hz when the short is removed. If a more accurate adjustment is desired, readjust R42 away from zero beat in a clockwise direction so that the LED flickers at about 10 beats/second, and then remove the short. This should result in an output very close to 1200 Hz.

Important Note (80A Version Only)

In the compare mode, the 1/4, FULL, 1/2 vertical scan switch must be in the FULL scan position in order to allow the divider chain to divide by 256.

Crystal Specifications

The crystal used in my model was ordered from International Crystal Mfg. Co. Inc., 10 North Lee, Oklahoma City OK 73102, according to the following specifications for 1200 Hz output: Frequency – 307,200 Hz, .01% tolerance; Type – GP; Calibration – room temperature; Holder – F605 (HC 6/U); Circuit Load – use Fig. 2.

The frequencies for other SSTV outputs are:

OUTPUT	CRYSTAL
1200 Hz	307,200 Hz
1500 Hz	384,000 Hz
2300 Hz	294,400 Hz (divide by 128)

Other Configurations

Other configurations that used the crystal controlled 1200 Hz output signal gated directly into the SSTV output during sync time were considered and analyzed. The 80A VCO mode was found to maintain more than sufficient stability at considerably less cost. These other designs are available by SASE.

Conclusion

The calibration capability described in this article provides the missing link towards ease in obtaining accurate alignment of not only the SSTV camera, but also the SSTV station monitor. An A-B comparison using the crystal controlled source calibration vs. a Yaesu model YC-355D has shown no significant difference in accuracy, but a substantial difference in cost. ■

What's All This Wire-Wrap Stuff?

--talk about cold solder joints!

The advent of digital electronics in amateur radio has paved the way for a new method of construction practice already widely used in industry. This is called the Wire-Wrap* method. One might ask, why Wire-Wrap? Just talking about the number of lines coming from an IC could make one's head reel. For example, let us assume that we have thirty 16 pin ICs, and that we have just one wire per pin as either a voltage, a ground, or a signal line. We now have 16 x 30, or 480 lines to interconnect. Can't you just picture the complexity of the printed circuit board required to accommodate such a circuit? Note that I'm talking about a 16 pin IC in this case. Now we are well into LSI and MSI with 24, 36, or 40 pin ICs becoming very popular. This is one reason why industry has gone the Wire-Wrap route. The mechanical design effort in laying out such a PC board is a time-consuming, costly operation. Most of the time a double-sided PC board with plated-through holes would have to be used. And in even more complex circuits, multi-layer boards would have to be designed.

A second advantage of Wire-Wrap over PC is the ease with which a design change can be accomplished. All one needs to do is unwrap the wire and put the new one in between the proper two terminals. We all know what it is like to modify a PC board. I have several scarred fingers from a slip of the knife as proof.

Now let's talk about some of the electrical and mechanical attributes of Wire-Wrap. A Wire-Wrap connection consists of approximately seven turns of 30 AWG solid copper wire. The wire is wound about a 0.025 inch square terminal in a helical manner, without the aid of solder. As the wire is wound about the terminal, the corners of the terminal bite into the wire, as the wire notches the sharp corner of the terminal. In this manner, a gastight, oxidationfree joint exists between the terminal and the wire. As the connection ages, a solid state diffusion process takes place, which enhances the mechanical strength of the connection. Through exhaustive tests it has been determined

* The term "Wire-Wrap" is a registered trademark of Gardner-Denver Co.

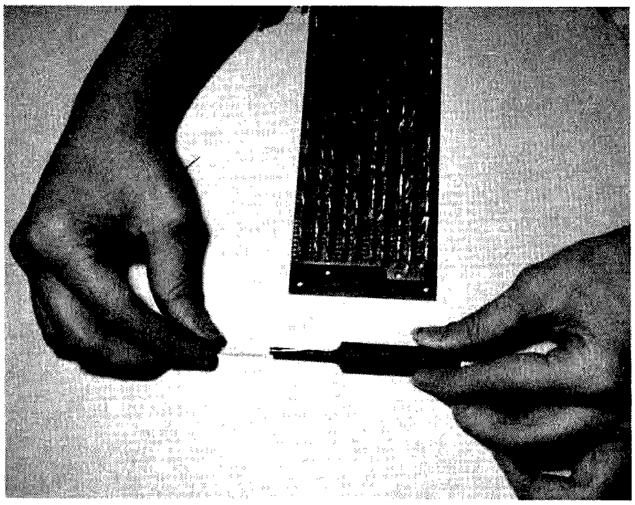

Fig. 1.

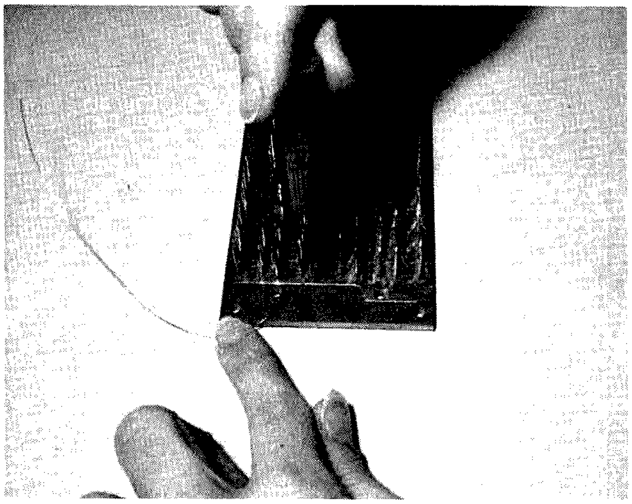

Fig. 2.

that a Wire-Wrapped connection has a life expectancy in excess of forty years. This tremendously exceeds the reliable life of a solder connection.

Wire-Wrapping can be accomplished through several methods. There are hand Wire-Wrap tools which are readily available and inexpensive. If many wraps are to be done, I would suggest the electrical hand gun; where a small run of similar boards are to be Wire-Wrapped, there is the semi-automatic method. A "head" with a Wire-Wrapping bit is indexed over the proper terminal through the use of a numerical controller. The fully automatic method would be chosen on a large run of similarly Wire-Wrapped boards.

Let's go through a step-by-step procedure to show the simplicity of the Wire-Wrap process:

Step 1. Insert the stripped end of the wire into the tool, as shown in Fig. 1.

Step 2. Place the tool with the wire over the terminal (Fig. 2).

Step 3. Twist the tool clockwise, until the stripped portion of the wire is used up in the wrap.

Fig. 3 shows a completed "modified" wrap. "Modified" means that there is approximately one turn of insulation around the terminal for strain relief.

Well, that about "wraps" it up. ■

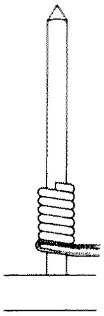

Fig. 3.

The staff (both of us) at ON_LINE wish to acknowledge our readers and advertisers as being the true cause of our successful first year. Our thanks and wishes for a 1977 full of events, satisfaction and peace.

with an Altair . . . it has an 8800 with floppy disk, Imsai, Wavemate, Jolt, Apple, Southwest Tech, Sphere, Ebka, Intelligent Systems, Astral 2000 . . . various cassette systems such as the National Multiplex . . . printers by Southwest Tech, Teletype, Dec, MPI . . . terminals by Lear, Burroughs, Intelligent Systems . . . etc.

With this lab Kilobyte is able to check out the many systems available to the hobbyist . . . to interface I/O systems . . . to check memory and other new modules . . . and (most important) to check out programs submitted to Kilobyte for publication or for royalty distribution.

KILOBYTE TO SUPPORT COMPUTER STORES

Older hobbyists will recall that publisher Wayne Green predicted the proliferation of the computer store even before the first one was opened. Kilobyte will be available in every computer store that meets the Kilobyte requirements . . . as will the Kilobyte program cassettes.

In August 1975 the very first computer store was opened (in California) . . . by August 1976 there are over 50 recognized computer stores . . . and perhaps 150 one-man shops which hope to grow into stores soon. Considering the growth of the hobby computer it will not be surprising to many if there are about 500 stores by August 1977 . . . and 5000 by 1978.

Since only hobbyists have the wide background in all phases of computers to provide the services of a computer store, a great many of the readers of Kilobyte will find themselves faced with an economic opportunity of a lifetime . . . once they are qualified. This is all the more reason for getting your own computer system . . . and reading Kilobyte.

KILOBYTE TO COST ARM AND LEG AT STORES

Since Kilobyte is going to be a good deal better than the other hobby magazines it is only reasonable that it should be a little more expensive. $2.00 per copy at your stores.

WHO IS BEHIND KILOBYTE?

The staff of 73 Magazine will be putting Kilobyte together . . . it is a staff of over 40 people and every aspect of publishing is done right at the big 73 Magazine headquarters building in Peterborough except the actual printing of the magazine. Kilobyte requires very large web offset presses and equipment, so it will be printed in Columbus, Ohio . . . and mailed from there.

The editor, John Craig, has been running the I/O section of 73 Magazine since last February . . . a section of about 40 pages of hobby computer articles and advertising every month. Before that John was one of the editors of the famed Cabrillo newsletter. John works out of Lompoc, California.

At the Kilobyte/73 headquarters the type is set, articles proofread, pasted up, artwork prepared, advertising sold and prepared for publication, subscriptions and readers service handled by a professional group which has been working together for years. Add to this the new Prime computer system and you have a first rate organization. Visitors to New Hampshire are invited to join the thousands of amateur radio operators who visit the HQ and say hello.

WHO IS THE KILOBYTE PUBLISHER?

Wayne Green is not totally unknown in the hobby computer field. It was his frustrations with trying to get a computer system to use with 73 Magazine that resulted in his idea for Byte magazine in 1975. In a period of seven weeks Green managed to find an interim editor, get enough articles to get the magazine started, get mailing lists of prospective subscribers, write letters for subscriptions, get envelopes printed, send out the subscription letters and get in enough subscriptions to warrant printing 15,000 copies of the first issue . . . far too few, it turned out . . . but a lot more than the 2000 envisioned at first.

Green's visit to the microcomputer manufacturers in August 1975 was reported in detail in Byte and did a lot to help this small new industry grow. Green has followed this 1975 visit up with one in August 1976 and this will be reported in the first issue of Kilobyte.

Green started publication of 73 Magazine in 1960 and gradually built it from a one man operation to the present staff of over 40. 73 is the fastest growing ham magazine . . . over 30% increase during the first six months of 1976 . . . and soon will be the largest in circulation in the ham field. It is already more pages than any others and has more advertising.

Green, who is listed in the latest issue of Who's Who, in addition to being the editor and publisher of 73, starting Byte last year (no longer connected with Byte), also is the writer of a nationally syndicated newspaper column on CB radio.

MANUFACTURERS WHO CANNOT ADVERTISE

The 73 Magazine policy of not permitting firms to advertise where there are problems of stability, of service, a questionable product, etc., will be carried on in Kilobyte. Unless current problems with Minimicromart, Processor Technology, E&L instruments and Ebka are resolved you may not be seeing them in Kilobyte.

CAN YOU GET RICH VIA KILOBYTE

Of course you can! With Kilobyte paying about double what the other hobby computer magazines are (you *do* want to read the best authors, don't you?), you can parlay any field of expertise of your own into enough money to buy more hardware. Be sure that you know what you are talking about . . . and that you explain it simply, avoiding all the usual buzzwords. Write to Kilobyte, Peterborough NH 03458, or John Craig, RFD 100D, Lompoc CA 93436, for instructions on writing for Kilobyte . . . it's easy . . . and lucrative.

COMING ARTICLES

Articles have been promised for Kilobyte by some of the top people in the field . . . a rundown on just about everything available . . . a sort of super buyers' guide is being prepared by Eric Stewart of Computers and Stuff. This will probably run to three parts to cover everything. Eric started with his first store in Provo, Utah and then moved to the San Francisco area . . . he is moving to a larger building to try and keep up with the business.

George Morrow (Morrow's Micro Stuff) will be writing on cassette systems and interfacing . . . on a fantastically simple prototyping system he uses . . . Dennis Brown (Wavemate) will be writing about the benefits of wire wrapping and also give us the inside dope on how the Wavemate was designed . . . and why. We've also been promised good authoritative articles on the Jolt system, the new Godbout PACE computer, the Apple computer and the Z-80 CPU coming out by MITS. Marlin Shelly of MPI (printer) has promised an article on parallel I/O standards and connectors . . . George Tate of Computer Mart (Orange, Ca) will be writing on I/O configurations . . . Dick Wilcox, a teacher of computer systems in elementary schools will be writing about fundamental software terms . . . monitors, debuggers, editors, executives, and such.

WHAT ABOUT THE I/O SECTION IN 73?

This will continue, as it has, to bring fundamental computer info to radio amateurs through the pages of 73 . . . as well as computer applications for amateurs such as pointing beams for DX automatically, reading Morse Code, etc.

WHEN WILL KILOBYTE START?

The first issue will be out in December 1976 . . . dated January 1977. The deadline to be sure of getting this issue is November 1st . . . after that you may or may not, depending upon the demand. Remember what happened to Byte subscribers who waited.

Exploding the Power Myth

-- to set the record straight

Hubert Woods W9IK/XE1ZX
Calle Las Nubes 1760
Guadalajara 5
Jalisco, Mexico

It is widely believed, and often written, that reflected waves on an rf transmission line represent power flowing in the line toward the load and away from the load. Encouraged for many years by the teaching of a prestigious amateur organization, many amateurs take this belief as an article of faith.

But it is not only amateurs who so believe – some professionals do, also. They construct ingenious explanations of transmission line phenomena that are based on power flowing forward and backward on a transmission line terminated by a load not equal to the characteristic impedance of the line. They devise equations containing terms purporting to give the magnitude of power flowing toward the load and of power flowing in the reverse direction, and by subtracting one from the other get the "net power" flowing into the load. Never mind if the "forward power" is sometimes considerably larger than can be accounted for by the energy supplied by the transmitter in unit time – that is the way it must be, they say. Some of these professionals attempt to prove that "real power" flows both ways on the line, by referring to the readings of so-called directional wattmeters, and overlook the unproved and hidden assumptions that their explanation involves.

In this article I will attempt to show that power cannot correctly be said to flow in transmission lines in any direction. I will also point out inherent fallacies in some of the arguments presented to support the notion of power being associated with reflected waves. To accomplish these purposes, it will be essential to have a clear understanding of the basic definitions of energy and of power, and of the differences between them. In physics, *energy is the capability for doing work.* A bent spring possesses energy; a charge of gunpowder possesses energy; an electric current possesses energy because it can run a motor, or generate heat in a resistor, or be transformed into electromagnetic waves which then do work. In such cases, the work done (or heat generated, or electromagnetic waves produced) is also energy in other forms, in compliance with the laws of the conservation of energy.

Power is defined in the ARRL *Radio Amateur's Handbook* (50th edition, p. 22) as *the rate of doing work.* However, the ARRL now prefers (ref. 1) a somewhat different wording, taken from the *IEEE Standard Dictionary of Electrical and Electronic Terms* (1972 edition), as follows: *Power is the time rate of transferring or transforming energy.* To avoid any misunderstanding with the ARRL over the correct definition of power, I will use the one it prefers. A careful look at this definition shows clearly that the words "transferring" and "transforming" in that definition refer to energy, not to power. The definition would become absurd if it were taken to mean that "power is the time rate of transferring or transforming power." Therefore, the thing that is being transferred in an electric circuit or transmission line is energy, not power. The thing being transferred, energy, is what flows on the line, and any assumption that the definition supports the conclusion that power flows on the line is wholly unwarranted.

There is another cogent reason supporting the view that power does not flow in transmission lines. Power is a scalar quantity, that is, a quantity completely specified by a number (of basic units, such as the Watt) and having no direction in space, as contrasted with a vector quantity which requires not only a number but also a direction for its complete specification. Because power has no direction, it cannot correctly be said to flow in any direction (ref. 2). But what of the power quantity (E) (I) (cos Θ) as measured at the line input? Does this mean that power is flowing in the line? No, it does not. It means that the flow of electric energy in the line is such as to cause work to be done at the rate of (E) (I) (cos Θ) at some suitable place or places in the circuit, namely at one or more resistive loads (ideally, only in the equivalent radiation resistance of the antenna).

I know that it is commonplace to speak of power as flowing in rf and other electric circuits, and such informal speech often carries a useful, if inexact, meaning. But, in dealing with the rather complex phenomena on rf transmission lines, it becomes essential to use such terms as energy and power in accordance with their exact meanings.

Having discussed the basic definitions of energy and power and their significance, we can now examine some of the fallacies offered in support of the conclusion that reflected waves on a transmission line represent or contain power flowing in two directions.

1. An equation has been published (ref. 3) in the following form:

$$P = \frac{(E^+)^2}{Zc} - \frac{(E^-)^2}{Zc} = \text{"Net Power Flow"}$$

in which, to use the author's words, "the first term to the right of the P expresses the power associated with the incident wave, and the second term, the reflected power."

This equation treats power as if it were a vector quantity; it clearly implies, as do the author's words, that power flows both ways on the line simultaneously, and that power flowing one way can cancel, partially or wholly, the power flowing the other way. All of this is in direct conflict with the fundamental definition and meaning of power, as previously discussed.

2. It is sometimes claimed that the readings of "directional wattmeters" prove that power flows both ways on the line, thus representing power associated with the incident and reflected waves (ref. 4). These instruments are actuated by samples of the line current and line voltage (ref. 5). There is no uncertainty about the derivation of these meter readings. However, endowing these readings with meaning with respect to power in the incident and reflected waves requires two assumptions: first, that the incident and reflected waves have a physical existence on the line; and second, that they represent power flowing on the line. Neither of these assumptions is automatically shown to be correct by the meter readings themselves, which, as stated, are actuated by line current and line voltage, and which would continue to be the same readings obtained from the same line current and line voltage with the same phase angle *even if the incident and reflected waves had no physical existence on the line.* Thus the "directional wattmeter" readings do not prove that there is any power associated with these waves, or, in fact, that these waves have any physical existence.

3. When the line and load are considerably mismatched, the "directional wattmeter" indicates a much larger forward power (it is said) than can be accounted for by the energy output capability of the transmitter. This has been said to be "a normal condition which must exist in order for a mismatched load to absorb all the power delivered by the source, while at the same time reflecting a percentage of the total power it receives" (ref. 6). But as power is the time rate of transferring or transforming energy, how could the time rate of transferring or transforming energy *anywhere on the line* be greater than the energy put into it in unit time? This would be manufacturing energy out of nothing!

In summary, I have shown, I hope, by recourse to basic definitions and their meanings, that power does not flow in transmission lines or other electric circuits. I feel that there have been errors in some of the statements that have been published in support of the contrary view. It must therefore be concluded that reflected waves do not represent power flowing in a transmission line, in any direction. Let us hope that professionals (and amateurs, too) will take seriously the basic definitions of the terms they use so frequently. I confess that I have not always done so. ■

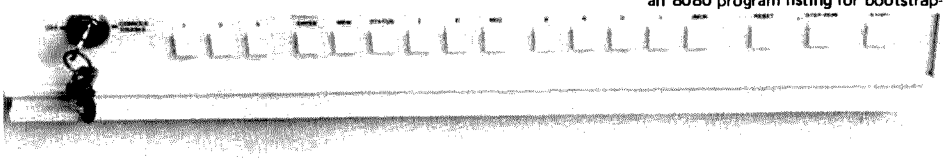
I/O REPORT



from page 74

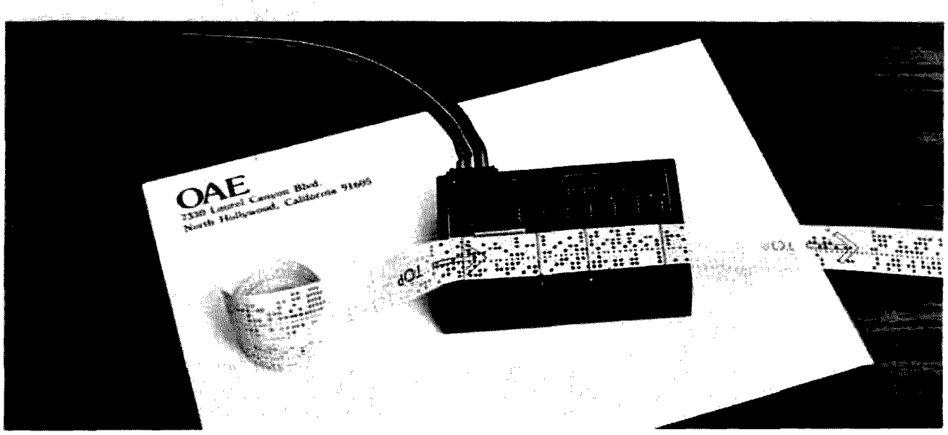
have any nifty software control of starting and stopping the tape.

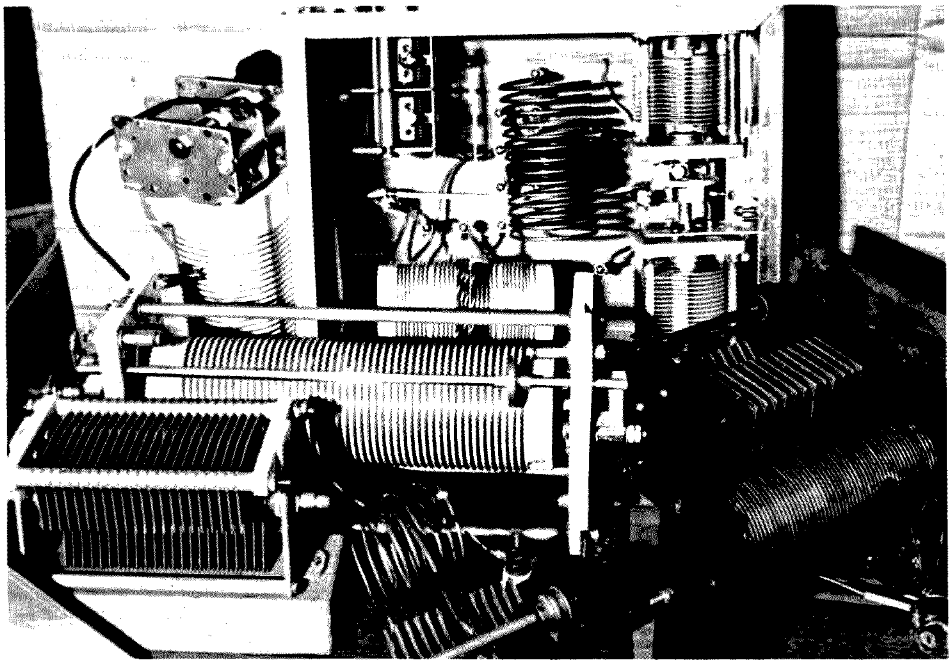
The manual provided with the reader is excellent. It includes the theory of operation, construction (if you buy it in kit form), parts list, interfacing instructions, schematic, board layout, and most importantly, an 8080 program listing for bootstrapping programs in from the reader.

Interfacing the OP-80A is a breeze. The diagram of the I/O socket shown here illustrates the interface signals. These include the eight data lines, an acknowledge and a ready line (the S1 and S2 status inputs are optional and can be whatever you desire). The "data ready" (or Reader Data Available) is generated from the sprocket hole and the acknowledge signal must be generated by either hardware or software from the computer. (We interfaced the OP-80A to our Varian V-73 and its paper tape controller was kind enough to provide us with an acknowledge signal. For an 8080-based system, an output port would be used to provide this signal through software.)

One item which is missing from the "posed" photograph is a small high-intensity lamp (using a 12 volt auto lamp) which is placed directly over the read station. The light intensity "alignment" procedure is simply a matter of placing the light over the read station until the SP (sprocket) LED comes on.

The OP-80A is available from Oliver Audio Engineering, 7330 Laurel Canyon Blvd., North Hollywood CA 91605. The price is $74.50 in kit form or $95.00 assembled and tested (add $2.50 for shipping and handling). A lamp kit option is also available at $19.95 and a tape transport unit will be available in the future (for you lazy types).





The graveyard of abandoned matchits.

Exploding the SWR Myth

-- to set the record straighter

As a regular user for years of end fed antennas, I have felt there should be some correct length, and some ideal or best way to tune the antenna and couple it to the transmitter. The latter item – the fabulous matchit – would peak up transmitted signal strength very well, rather like tuning a receiver pre-selector when receiving. (Admittedly a flatter response was expected, due to lower Q.)

Signal strength reports from contacts did not confirm this, nor did a remote pickup antenna, with diode and indicating meter. So tests were made to try to discover if the fabulous matchit existed, and to find it if it did.

As it had been amply demonstrated that an rf ammeter in the antenna lead gave maximum reading for maximum radiated signal, if operating frequency and the whole antenna-ground system remained unchanged, such a meter was used as the indicating instrument.

The Beginning

Putting the antenna directly on the Tx, Fig. 1(a) was the start. PA tuning and loading controls were far from their usual settings with the PA dipped, but PA grid and anode currents were noted, and also antenna current.

The roller-coil favorite matchit B was then introduced, set to its usual values. Complete readjustment of PA tuning was needed. Loading was set to get the same plate current as before. Hey ho, antenna current was exactly the same. Nor was any improvement possible, with changes to L and C, followed by PA re-tuning.

Never mind: Parallel tuning of this antenna length had often been used, so Fig. 2(a) was substituted. With customary adjustment of this parallel matchit, current shown by the rf meter was exactly as before. So both L and C were grossly changed from their "correct" values for the band, and tap T was moved to unusual positions. Provided it was still possible to load the PA to the noted input, antenna current was the same with all changes made.

Oh, Dear!

An excellent matchit well known for its ability to provide 1:1 swr on coax from the Tx was substituted, as shown in Fig. 2(b). With the swr at 1:1, antenna current stood at exactly the same figure as before. With the excellent matchit mistuned, 5:1 on the swr and PA dipped, antenna current was exactly the same.

Perhaps the antenna length was responsible? It was cut to length by the book, and was possibly humming with resonant energy?

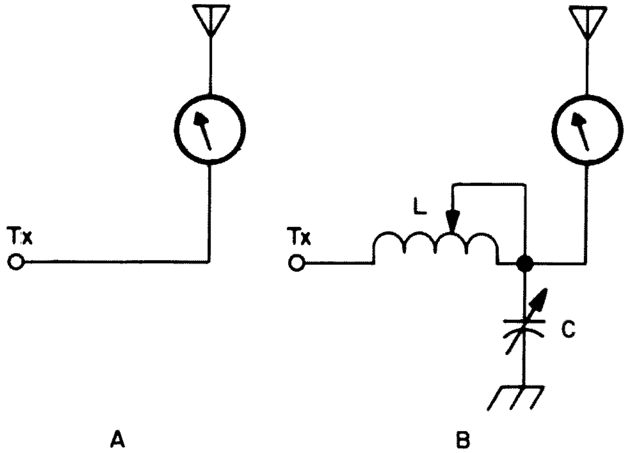

Fig. 1. Direct connection and roller coaster matcher.

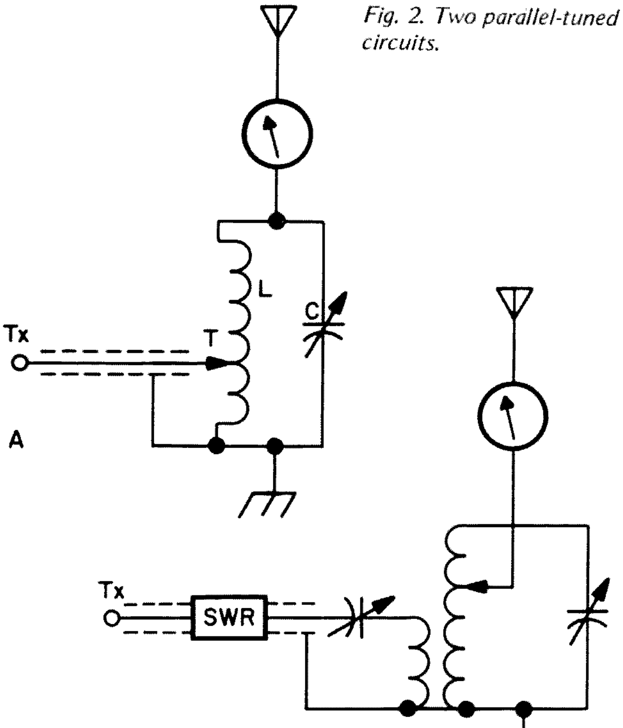

Fig. 2. Two parallel-tuned circuits.

No, changes to its length naturally altered the rf current, but starting again from Fig. 1(a), all remained the same.

Conclusion

Provided the PA can be loaded and dipped, any matchit, or indeed none at all, will give exactly the same signal strength. So what our favorite matchit does to justify its shelf space comes under other headings – it can bring an otherwise impossible antenna impedance within the range of the transmitter, it can let the Tx see a line with a low swr, if the Tx or a filter needs that, and it can be unfavorable to harmonics (especially Fig. 2). But apparently it will never change you from S5 to S9 plus, or indeed from S5 to S6. ■

Bring a Dead Band to Life

-- beacon CQer

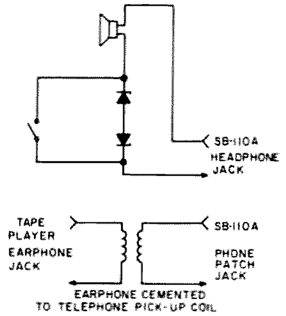

Fig. 1. Circuitry used to operate Heath SB-110A transceiver as a beacon station.

This revolutionary new concept in repeater design centers around an endless loop cassette cartridge. A thirty second CQ with calling instructions was recorded on a ninety second endless loop.

As the loop runs through a tape player, one hears the CQ followed by a minute of silence. When the player output is patched into a transceiver VOX circuit, the result is instant beacon. A word of caution on the patch: The dc component of the tape player output should be isolated from the VOX input to prevent nuisance tripping.

The only disadvantage I found with this simple arrangement is that it requires constant attendance at the transceiver. There are many times when I would prefer to listen for calls in my family room with the rest of the family. An extension speaker was easily added, but the wife would absolutely not condone the no-signal noise of the receiver. Obviously, a squelch circuit was in order. On the other hand, I had no desire to mutilate the transceiver or decrease its sensitivity.

An interesting problem indeed – how can the noise be squelched with minimum circuit disturbance? Low voltage zener diodes filled the bill. Two diodes, back to back in series with the speaker, will conduct only when their zener voltages are exceeded. Audio output level is adjusted so that the noise level is just below zener breakdown voltage. A SPST switch was added to short out the zeners for weak signal work.

I realize that this crude design could use some refinement, but I leave that to the perfectionists in our midst. ■

The IC-22 Walkie

- - portabilization with nicads

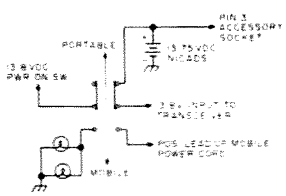

Fig. 1.

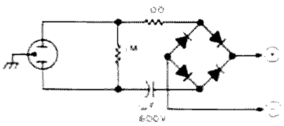

Fig. 2. Charger.

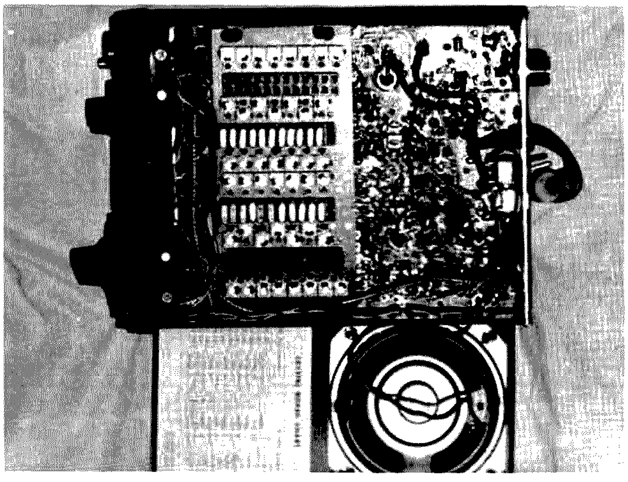
It all started with a desire to have a multi-channel, top quality performance, portable transceiver that I could carry with me on field trips, CD activities, repeater maintenance or just about anywhere.

Looking at the problem from several different angles, I immediately saw that the cost of a new HT was just about out of the question. External battery packs are usually cumbersome and heavy — even messy. I popped the covers off my ICOM IC-22A and to my surprise there was plenty of room for an internal nicad battery pack. In fitting the batteries inside, I wanted to make the fewest possible outside modifications to the rig, so as not to detract from its clean-cut design.

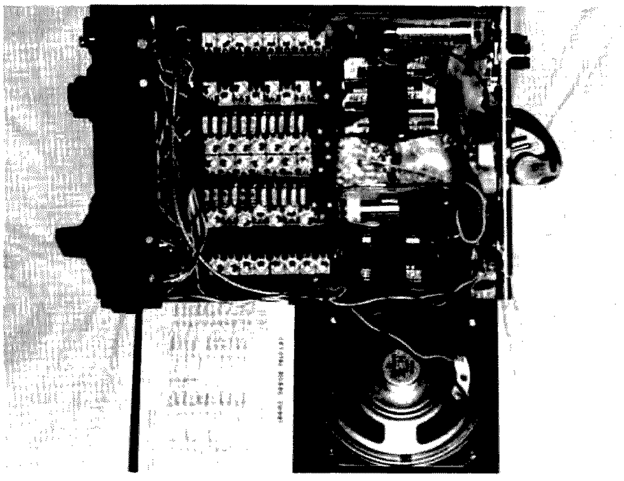
The first step in this modification is to turn off the light bulbs. Next, insure that the normal external power source and the internal nicad pack are not paralleled together. I mounted a miniature DPDT toggle switch on the rear panel to accomplish this objective. I needed a battery charger input, so I connected the positive side of the nicads to pin 3 of the 9 pin accessory socket; pin 8 is negative ground.

Before installing the batteries, I decided it would be best to eliminate the possibility of the batteries rubbing against the bottom of the PCBA solder etchings, so I placed a piece of heavy gauge clear flexible plastic over the PCBA etch side.

Due to the voltage require-



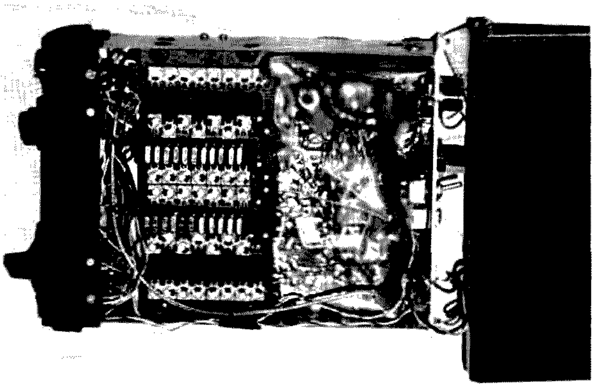
Empty space available.



Batteries installed.

ment for optimum performance of the IC-22A, I hooked up eleven AA nicad cells in series, making a 13.75 V dc battery source. Current drain with the lights off is approximately 40 mA standby, 85 mA RCV, and 550 mA transmit in the 1 Watt position. If you choose to replace the speaker with a smaller one, you could fit in two plastic 6 pack battery holders. But if you do as I did, and leave the original speaker in, you need one 4 pack, one 3 pack and two double pack battery holders. It is not as neat looking, but it does fit without changing the original speaker.

For a nice finishing touch you might make up something sharp, like a black leather suede carrying case with a shoulder strap. Then hook up a rubber duckie with a right angle connector, and away you go. ■



Flexible plastic protective covering.

The Latest in Counters

-- an inexpensive modularized 50 MHz system

Geoffry W. Kufchak WA1UFE
869 Reed Ave.
Akron OH 44306

I finally decided I needed a relatively simple but effective counter. It had to be easy to build and it had to be able to count to 50 MHz without using a prescaler. After giving the design approach considerable thought, I decided on the plug-in board method. Then I proceeded to break up the total circuit into the individual circuits that make up a frequency counter and design PC boards for each of them. Counter circuits are pretty basic and there are only so many ways to design one, so this one may look a lot like others. I did, however, add a few ideas of my own.

One of the worst features of any counter is the awful current drain that the LEDs in the display manage to consume. Even with current-limiting resistors, 8 digits at 20 mils per segment can pull 1.12 Amps. I got around this by scanning the display so that only one LED is on at a time. This reduces current consumption by one eighth. I also decided to get rid of that ridiculous number of resistors, since scanning the LEDs gave me a 10% duty cycle. This meant that the average current through the LEDs would be 10% of the maximum current without resistors. Checking the specs for the LEDs I was using (MAN8) showed that at 5 volts the maximum current per segment would be 192 mils (OUCH!). But 10% of that is 19.2 mils and is within the maximum of 40 for the LED. The maximum current drain is now reduced to 134.4 mils when the display is showing an 8.

Another change I made is the use of a 74LS90 as the first counter in the chain. The 74LS90 is pin replaceable for the 7490 and will count in excess of 50 MHz. Some designs use the 74196, which uses inverted logic as compared to the 7490. The 74LS90 uses the same logic so board design is simplified.

I also added the option of

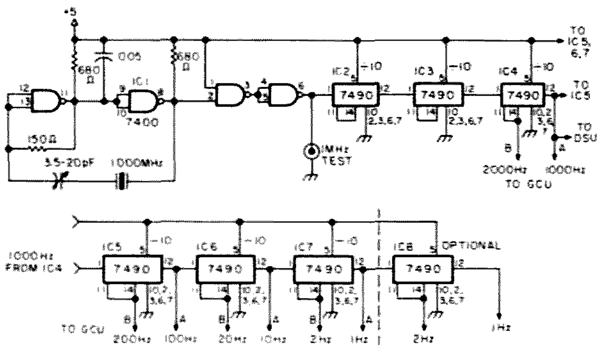


Fig. 1. Timebase Oscillator and Divider.

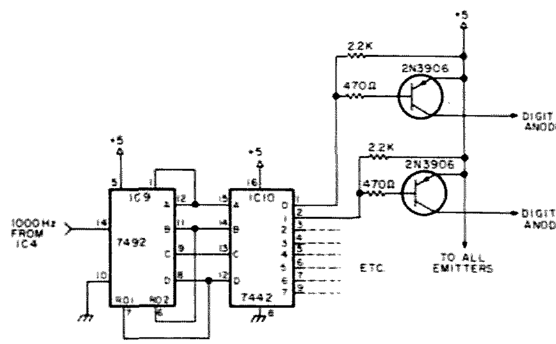

Fig. 2. Display Scan Unit.

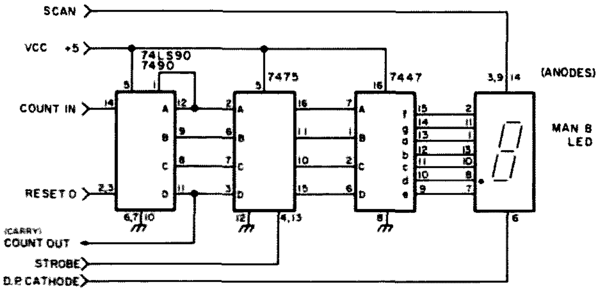

Fig. 3. Decimal Counter Unit.

selectable gates, .01 sec, .1 sec, 1 sec, and 10 sec.

Breaking the counter down into individual boards, there is the Time Base Oscillator and Divider (TBOD), Display Scan Unit (DSU), Decimal Counter Unit (DCU), Gate Control Unit (GCU), and Preamp. All these units plug into a master board which has all the interconnecting circuit paths etched into it.

Approximate cost, less cabinet, is about $85.00 using all new parts, less if you have a well-stocked junk box and can make the boards yourself.

Timebase Oscillator and Divider

The TBOD is constructed on a PC board that is 3.5" by 2". Due to the compactness of the circuit it was necessary to use jumpers for the frequency outputs. A double-sided board could be made and eliminate that need, but in the effort for simplicity I decided against it. The TBOD consists of a 7400 NAND gate for the oscillator and a series of 7490s wired to divide by 10 in the bi-quinary mode. This method gives a symmetrical square wave at the output, needed for proper gate timing. Also, the divide by 5 signal is brought to the edge of the board, as these frequencies are also needed. 1000 Hz is also used by the Display Scan Unit, so it has two outputs.

I was curious as to the stability of this circuit, since the crystal I'm using only has a tolerance of .005%, so I checked it against a 1 MHz signal with a known accuracy of 1×10^{-9}. I was quite surprised to find that it was as good as 1×10^{-8} after a one hour warmup, and held its accuracy hours later.

Provision has also been made for bringing the 1 MHz signal out to the back panel of the counter for checking it against another signal.

This is also the most expensive of the units, costing about $15.00 with all new parts.

Display Scan Unit

The DSU is also built on a 3.5" by 2" PC board. The DSU has a 7492 divide by twelve counter wired to reset to 0 at the count of ten. The BCD outputs of the 7492 are connected to the BCD inputs of a 7442 decimal decoder, which is used to scan the display LEDs by switching the Vcc on and off through a PNP switching transistor. The emitters of the transistors are connected to positive 5 volts and the collectors are routed to the anodes of the LED display. Pull-up resistors are used to keep the transistors biased off, along with current limiting resistors on the bases. If 5 volts does not provide enough brilliance from the LEDs, a slight modification on the board will enable you to use a higher voltage for switching to the display. Try not to use more than 10 volts, however. More than that and the LEDs may burn out.

The outputs of the 7442 are active low. That is, the output selected is at ground and all others are high. Grounding the base of a PNP transistor turns it on and switches Vcc to the proper LED. Because the 7492 is wired to divide by ten, the scan rate figures out to 100 Hz. This is fast enough to eliminate any flickering, but allows enough brilliance for normal room lighting.

With all new parts, the DSU costs about $6.25.

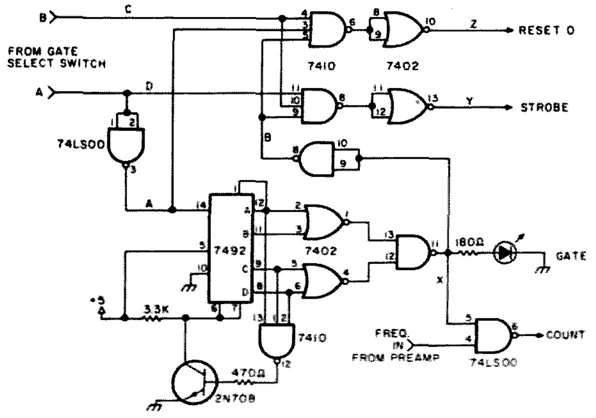

Fig. 4. Gate Control Unit.

Decimal Counter Unit

The DCU is constructed on a 3.5" by 1.7" PC board. Except for the first DCU, all use standard 7490s as counters. The first DCU uses the 74LS90 by Fairchild, which was described earlier, for a 50 MHz count rate. Also, each DCU has a 7475 quadruple bistable latch, a 7446 or 7447 BCD to seven-segment decoder, and a socket for the LED. Any Monsanto LED may be used here as the pin-outs for most of them are identical. I used the MAN8, which is yellow, simply because I had them. However, the large .6" MAN6 or the .27" MAN7 will also plug in. Both of these are red.

For the LED socket, use the already preformed side mount socket or be cheap and bend the leads of a wire-wrap socket like I did.

The 7475 is used to transfer the accumulated count of the 7490s to the display when strobed by the Gate Control Unit. A logic one is needed on the clock inputs to transfer the input information. When the clock is low, the latch will store the information until the next

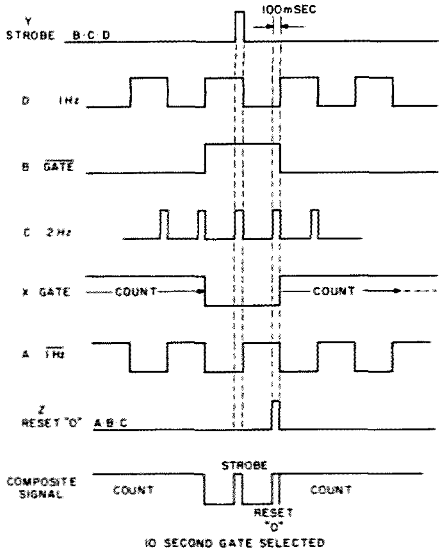

Fig. 5. Gate Control Timing.

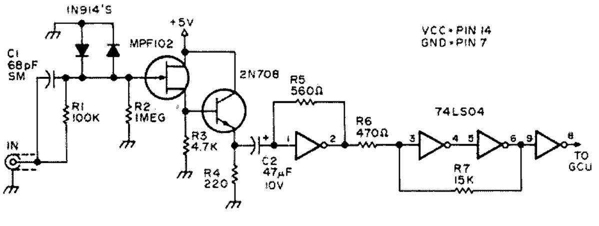

Fig. 6. The Preamp.

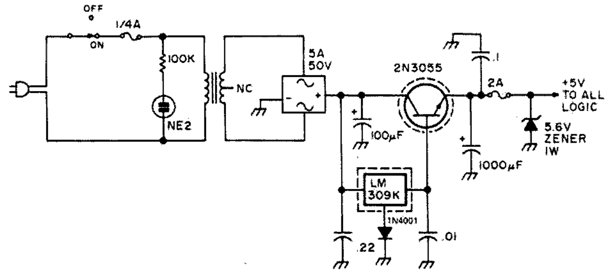

Fig. 7. Power Supply.

strobe pulse. If the input has not changed, the output won't either. If new information is present at the input, the outputs will change to agree with the inputs.

The outputs of the 7475 are connected to the inputs of the 7447 which decodes the BCD to the proper coding to display the corresponding decimal number on a seven-segment readout.

Four of the DCUs have provision for using the decimal point so that the display can be wired to show the frequency in either kHz or MHz. One need only wire the proper decimal point to ground through the gate select switch.

The cost of the DCU will be about $6.50 for the 50 MHz version, and a little less than $6.00 for the standard version.

Gate Control Unit

The original circuit I tried for this was unsatisfactory, as the time needed for the strobe and reset 0 pulses was equal to the gate time. On the faster gates this was no problem, but on a 10 second gate it could be annoying having to wait 20 seconds for updating the display. So I redesigned it with the basic idea that I wanted a 10 second gate and the resets to occur within one second. A look at the timing diagram may help in understanding the operation of this circuit. Refer to the schematic for lettered lines. Note also that the board has a gate LED incorporated on it, eliminating the need to front panel mount one. It will show through the display window to the right of the digits.

The GCU is built on a 3.5" by 1.7" PC board. It consists of four ICs: a 7492, divide by twelve; a 7410, triple-three input NAND gate; a 7402, quadruple two-input NOR gate; and a 74LS00, chosen also for the high toggle speed.

Let us assume we have selected a 10 second gate. Through the gate select switch, 1 Hz and 2 Hz signals are routed to the inputs of the GCU. One gate of the 74LS00 is used to invert the 1 Hz and apply it to the clock input of the 7492. Normally this IC would count to twelve and reset to 0, but with the 7410 gate connected to the A, C, and D outputs, it will be forced to reset at the count of eleven. Zero detecting the outputs with a NOR gate and NAND gate will produce a pulse that is high for 10 seconds and low for one second, which is the time between reset and the next input cycle. Another gate of the 74LS00 is used to invert this pulse.

By combining the inverted gate pulse with the 1 Hz and 2 Hz signals, and then inverting the outputs of the other two gates of the 7410, the Strobe and Reset 0 pulses are generated and transferred to the rest of the counter. Through trial and error it was found that there had to be a minimum amount of time between the two pulses and this circuit provides it. Unfortunately, due to the minimum pulse width needed to reset the 7490s in the counter (50 nsec), the fastest gate time allowable is .001 second. This is probably faster than needed anyway.

The current limiting resistor for the LED should be chosen for the particular LED being used. Generally, about 180 Ohms should be right. Any color may be used; I used yellow to match the display.

This is also the cheapest unit, costing about $4.00 with all new parts.

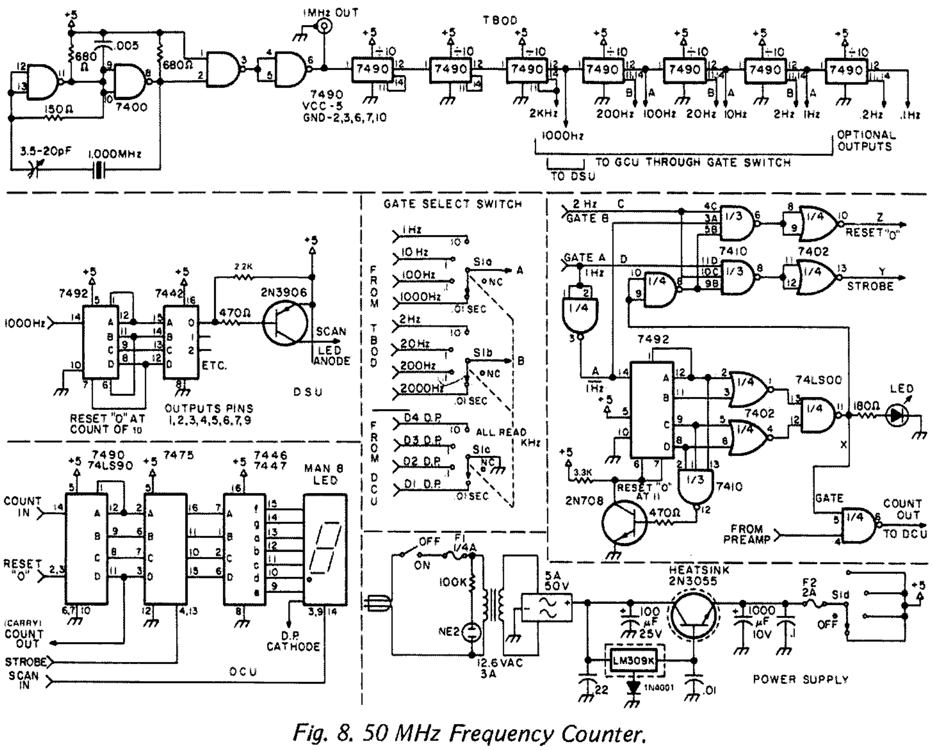

Fig. 8. 50 MHz Frequency Counter.

The Preamp

I finally found a Preamp circuit that would work. I had tried several others that had been published, but had terrible sensitivity. This one I discovered while reading back issues of *73*. It is from the "Latest K2OAW Counter Update" in the May, 1975 issue by WB2UKP. Some minor changes were made, though. I used a 74LS04 to obtain a 50 MHz working speed, a 2N708 for Q2, and a

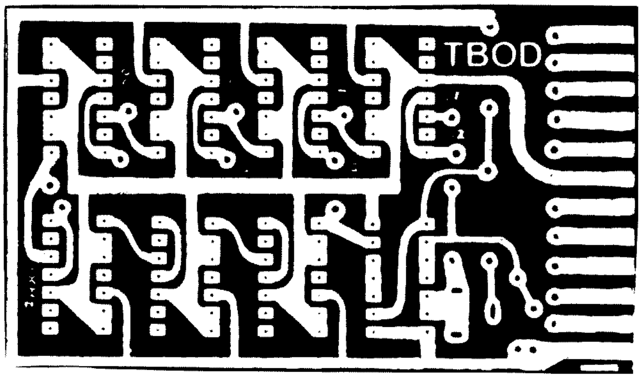

Fig. 9(a). TBOD board (full size).

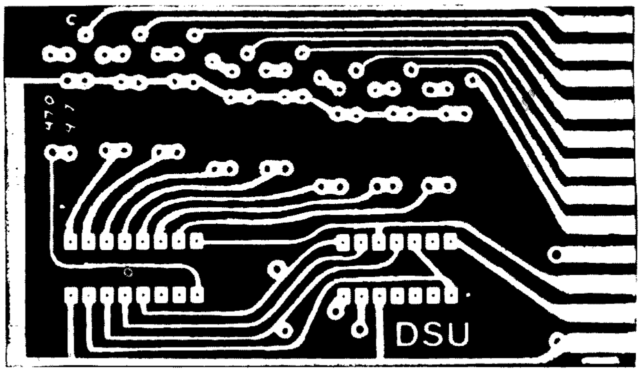

Fig. 10(a). DSU board (full size).

slightly different input scheme. Finally, sensitivity became livable. A scope and rf signal generator (HP 608D) showed a sensitivity of 10 mV from 10 MHz on up. At audio frequencies, about 50 mV was needed for reliable operation.

The reason for all that extra space on the board layout is that I hope to, in the future, incorporate an on-board prescaler using the 11C90 by Fairchild. Provided, of course, that the circuitry is as simple as that using a 95H90. With the 11C90, the counter should operate in excess of 500 MHz.

Power Supply

Due to the heavy current demand, about 1.3 Amps, I decided on the circuit shown to regulate the five volt line, rather than use two LM309s. All components can be mounted on the rear panel with appropriate mounting hardware and solder lugs. Heatsink the pass transistor and LM309K. You can use a bridge rectifier module or individual diodes. They should be rated for at least 5 Amps at 50 volts. The transformer is a 12.6 V ac at 3 Amps, or parallel two smaller rated ones. Use a 2N3055 for the pass transistor or a suitable substitute with similar ratings. The neon pilot light is not really needed, but I like little frills to dress up a front panel.

The fuses should be of the fast blow type. Fuse holders mounted on the rear panel is the best method, but they can be soldered in inside the chassis. The power switch can be eliminated so that the counter is on whenever the line cord is plugged in.

General Construction and Testing

After etching and drilling all the boards, install the jumpers first because two on the GCU are under ICs. Next put in the resistors and capacitors, and then the transistors and ICs. The LED sockets on the DCUs come next; then install the LEDs. Install the sockets on the master board.

Wire the power supply in the case, along with the front and rear connectors and switches. Secure the master board to the case with small angle brackets, at least 4 inches behind the front panel. This will allow the boards to be installed and removed easily. Or the master board may be hinged at the bottom to tilt back. Next do the main wiring from the power supply to the master board and the front panel switches. Use RG-174 for the counter input and the 1 MHz test output. Location of the controls and cutouts is entirely up to the builder and depends on the case used.

Before installing any boards, check the power supply for proper operation. If it's working, turn the power off and install the TBOD in the 12-contact

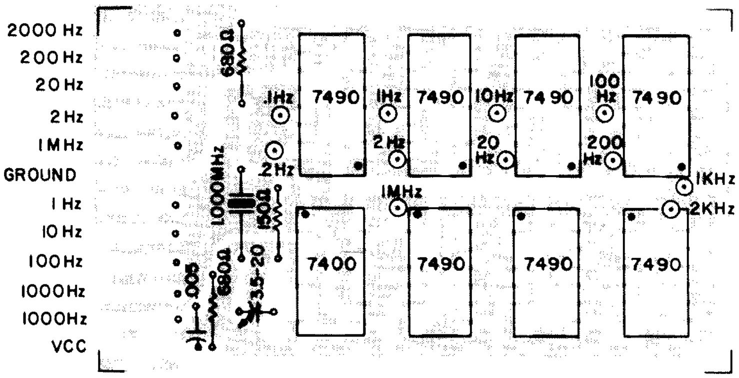

Fig. 9(b). TBOD component layout. Use jumpers to bring frequency outputs to edge. 1 board per counter. Dot indicates pin 1.

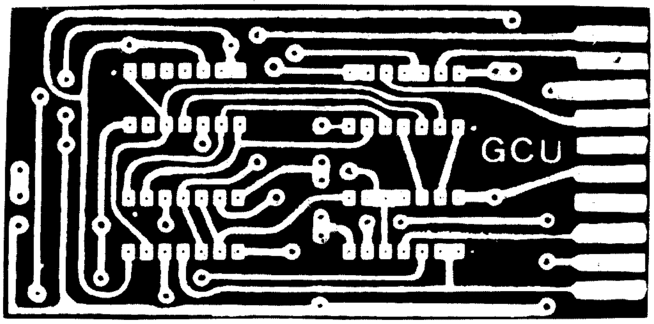

Fig. 12(a). GCU board (full size).

socket on the left (from the front of the counter). An accurate frequency counter will be needed to set the 1 MHz oscillator, at least 1 x 10^{-8}. Turn the power on and with the counter connected to the 1 MHz test output, adjust the trimmer to read 1 MHz, plus or minus a few Hertz. If it won't adjust, try another 7400. This is an initial adjustment. After the rest of the boards are installed, and at least a one hour warmup period, recheck the frequency. Before turning off the power, check the divider chain for proper frequency outputs. If everything checks out, turn the power off and install the GCU board. Select the one second gate and turn the power on. If the GCU is working, the gate LED will blink on for one second and off for 10 msec. Check the Reset 0 and Strobe outputs with a scope for a 10 msec pulse. If the GCU checks out, turn the power off and install the DSU board.

Turn the power on and check each of the DSU outputs with a scope for proper switching. A frequency of 125 Hz should be measured. If the DSU is working, turn off the power and install the DCUs. Turn on the power and check that the display reads all 0s. If not, make sure all the boards are in the sockets tight or check for unsoldered connections, or bad ICs. If all 0s are displayed, turn off the power.

Install the Preamp board and turn the power on. The display should still read all 0s. If not, the DSU may need bypass capacitors on the Vcc line on the master board. Any signal on the Vcc line greater than about 20 mV will trigger the Preamp and cause false counting with no input. Any input signal will have to exceed this by at least 10 mV to be counted. This has been one of my headaches with my counter, although I know I have a bad 7442 in the DSU which is causing the problem.

If you get all 0s on the display, proceed to check out the whole counter by using a signal generator to check the frequency response and sensitivity. You may want to keep a graph or record of the results for future reference. My counter showed a sensitivity of 50 mV from 10 Hz to about 35 kHz, and from 10 MHz on up, about 10 to 15 mV. I didn't have any way to check the frequencies in the middle.

All that's left to do is recheck the TBOD frequency and button up.

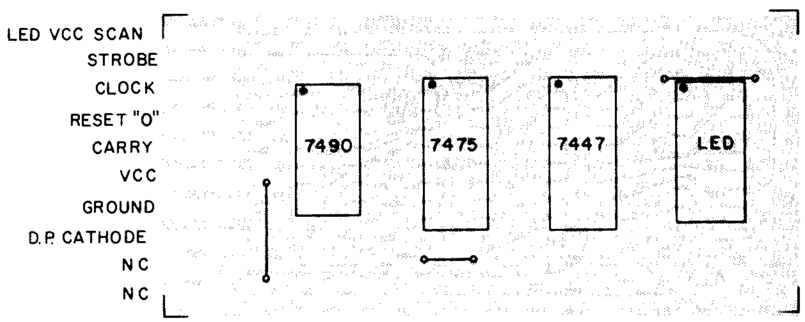

Fig. 11(b). DCU component layout. Use side mount socket for LED (see text). One DCU uses 74LS90 for 50 MHz count speed. 6 or 8 boards per counter. Dot indicates pin 1.

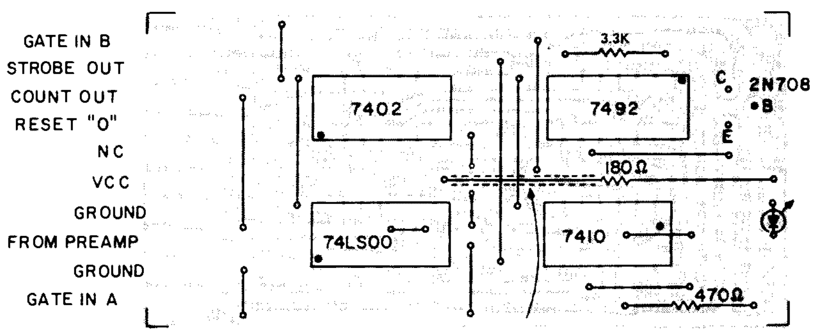

Fig. 12(b). GCU component layout. Use sleeving to insulate resistor lead. 1 board per counter. Dot indicates pin 1.

Troubleshooting

If you run into difficulty getting the oscillator to zero on exactly 1.000 MHz, try another 7400. Some will oscillate better than others. It has something to do with the characteristics of different batches. You can use a scope or another counter to check the divider chain for proper division. On the GCU, a dual-trace scope is nice because you can check and compare the waveforms at more than one point and reference them to another. Most problems here are caused by loose ICs in the socket – for me, anyway. Actually, most problems can be cured simply by trying a different IC. If you still run into difficulty, look for solder bridges, bad connections, wiring errors, or even the possibility of a leaky or bad transistor. Well, what more can I say? Have fun

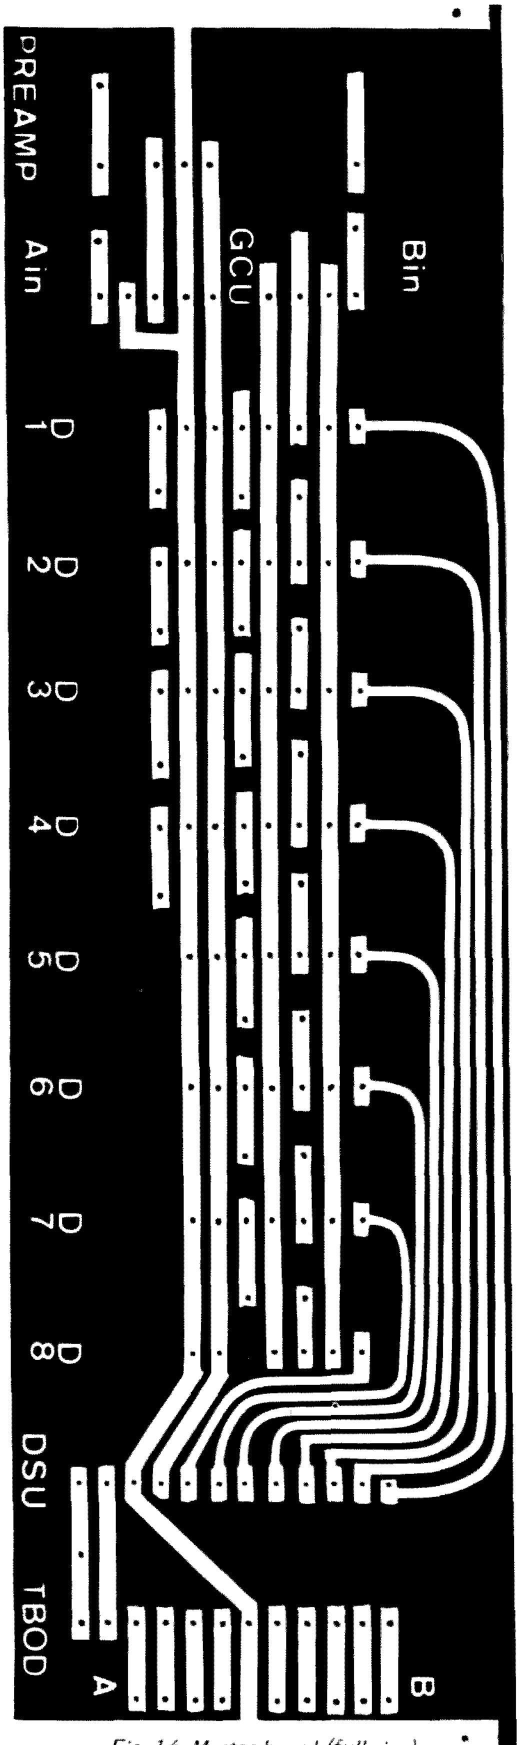

Fig. 14. Master board (full size).

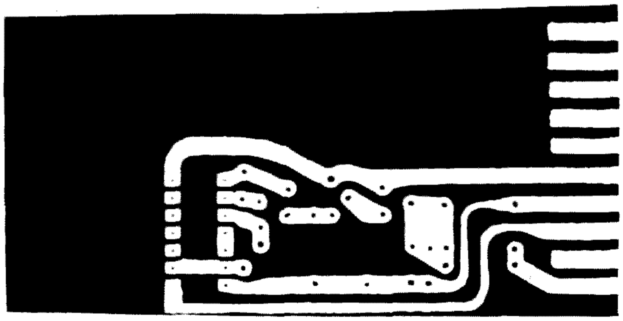

Fig. 13(a). Preamp board (full size).

counting!

Afterthought

One can save in construction costs by not using sockets for the ICs, although it's a good idea to make certain the IC is good first. It's not fun unsoldering them. Do use sockets for the LEDs, though. The preformed side mount ones are best, but a wire-wrap socket will do just as well if you carefully bend the leads with needlenose pliers.

Try for a trade-off between price and visibility on the display. Sure, those large .6" LEDs are easy to read, but expensive. The cheaper, .27" ones will work just as well, and they can be had in different colors: red, green, yellow, or even orange. Check the ads in the back of *73* and I'm sure you'll find something.

The Amphenol PC card sockets are available from Cramer International, Newton, Mass., or the local office in your area.

The cabinet will have to be at least 3½" high, 10½" long, and 7" deep. Make sure you leave at least ½" between the LEDs and the back of the

front panel for removal of the plug-in cards.

If you don't need more than one gate, eliminate the switch and hardware the circuit. The switch I used is a four-pole, five-position, non-shorting miniature rotary, Centralab #PS-11. The extra position and pole made it possible to turn the power on when selecting the timebase.

Also, since I used a new GCU, I found that I could eliminate the last 7490 in the TBOD. Or leave it in if you want an accurate .1 Hz signal for something.

I had a lot of fun designing the counter, but it was not without its headaches. I'm just happy it works. ■

The 5 Minute COR

-- simplest yet?

Steve Uhrig WA3SWS
3893 Jumper Hill Lane
Ellicott City MD 21043

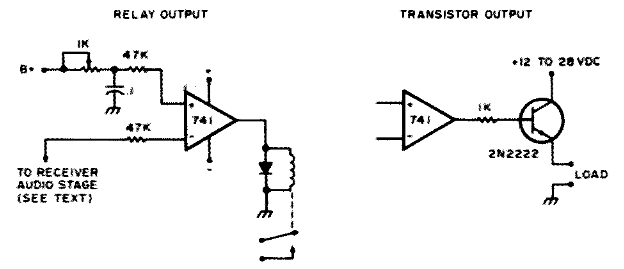

Fig. 1. Universal COR schematic.

Anybody building a repeater or a remote base needs a carrier operated relay (COR). A COR is a usually simple device that hooks into an FM receiver and closes a relay when a carrier comes in on the receiver. The relay can be used to activate a transmitter for repeater applications or activate any of a number of other devices for special purposes such as tape recorders, meters or alarms. Presented here is what I believe to be the simplest circuit for a COR around. Unlike most other circuits, this one will work on any receiver, vacuum tube or solid state.

This circuit was designed for mobile applications. I wanted something simple, solid state, rugged and reliable. The final draft meets all of these specifications. I have two of these circuits in my car controlling an onboard repeater that will relay 450 MHz to 146 MHz and vice versa. With the repeater installed in my car I am able to use a 450 MHz hand transceiver and work back to the car, firing up my 2 meter mobile with 150 Watts on any VHF channel. This makes the equivalent of a 150 Watt HT with a 5 dB antenna. It works real well, but people I talk to can't understand why they hear 5 squelches drop out.

Now for an explanation of the circuit. The whole idea centers around any old op amp you have lying around (within bounds of reason, of course . . . it works better if the op amp is not burned out). I have had the best luck with either the 741 or the 709 op amp, but several others should work also.

As shown in Fig. 1, the circuit is simple and straightforward. Let's review the basics of how op amps work. Keeping this explanation in mind, the workings of the circuit in Fig. 1 should be obvious to the most casual observer. An op amp is an analog device. In a nutshell, the gain of an op amp (operational amplifier) is very high. Gains of 100,000 to 500,000 are not uncommon. Of course, the output can never go higher than the supply rail, so you can see that an input to an op amp of 1 millivolt will give an output of 10 volts even if you run the gain at only 10,000. Notice the inputs in Fig. 1 marked + and -. These are called the noninverting and inverting inputs respectively. The op amp amplifies the *difference* between these two inputs. In this application for the COR we are using the op amp as a comparator. I will stop here for a moment and give a quick review of the workings of a squelch circuit in an FM receiver. See Fig. 2 for a block diagram of a squelch circuit.

The output of the discriminator will have noise on it when there is no incoming signal present. When a signal does present itself, the noise will quiet. A squelch circuit is designed to turn off the audio stage in the receiver when no signal is present so the operator does not have to listen to the noise. With no signal coming in, we said there would be noise at the output of the discriminator. This noise (ac) is rectified and the dc is amplified by the noise amplifier. The dc signal developed is used to conduct another transistor which in turn shunts any audio present at the audio stage to ground. When a carrier comes in, the noise will quiet. With no noise present at the rectifier in the squelch, no voltage is developed and the audio amplifier operates normally. Now here's where our carrier operated relay does its thing. Hang a voltmeter across the emitter-collector junction of the audio amplifier transistor. With the stage off, there will be a difference in current flow and therefore voltage across this junction.

Notice the inverting input of the op amp in Fig. 1. This input is hooked directly to

the collector of the audio amplifier preamp transistor. You can see now that there will be a higher voltage on this input when the transistor is turned off than when it is amplifying. The non-inverting input of the op amp is tied to a reference voltage, in this case B+. The reference voltage will remain constant, but the voltage on the other input will shift when a carrier comes in on the receiver and turns on the audio stage. The op amp will amplify the difference and drive the output to the full supply rail voltage with as little as 1 millivolt between the inputs. The output voltage can be used to trip either a low current relay or it can turn on a transistor. I used a reed relay, but any type with a coil current of less than 75 mA is acceptable. Check the specs on your particular op amp before using anything that might draw this much current. Under no circumstances draw more than 100 mA from the op amp.

The 1k pot on the non-inverting input of the op amp sets the reference voltage. The setting here will depend on where and how you hook the op amp to the receiver audio stage. Set it so the COR trips reliably on an incoming signal. Try to keep this voltage as low as you can and still keep the circuit operating properly. The 47k Ohm resistor limits maximum current on the input. There are probably about six places where you can tie the inverting input of the op amp to the receiver. Anywhere you have a voltage change between signal and no signal will work. If it doesn't work the first time, swap the leads to the + and - inputs. It may be that you have picked a point where the voltage swings in the wrong direction. Don't leave out the diode across the relay coil. When the relay opens up, there is a big voltage spike that could damage the op amp if the diode wasn't there to shunt it.

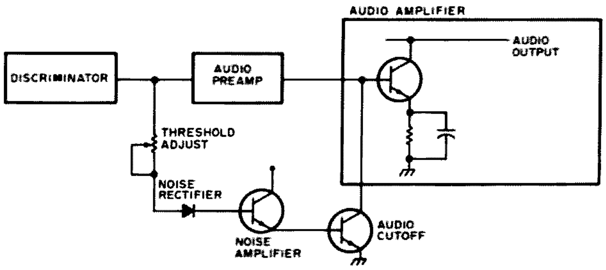

Fig. 2. Block diagram of squelch circuit for FM receiver.

Another interesting use for this COR besides repeater applications is to use it to inhibit a clock on a scanner. Use the transistor output and when a carrier comes in on the receiver you can kill the clock and lock the scanner on that frequency. When the carrier drops, the clock will start up again and resume scanning. It is possible to put a capacitor in the circuit to delay the transistor shutting off immediately if you should want the scanner to wait a few seconds so you don't miss any possible reply on the channel that was just active.

Well . . . here you have it. Construction is simple. I build my versions on the little printed circuit boards available from Radio Shack. They're a convenient way to do it and are small enough to fit in anything larger than a TR-22. If you desire to use the COR on a vacuum tube receiver, build a voltage divider on both inputs to keep the operating voltages around 15 or 20 V dc. Voltage from the push to talk line should be of acceptable quality to power the op amp if you filter it a little bit.

There are lots of uses for CORs. They're a lot of fun to play with. ■

See the World and Get Paid!

-- merchant marine radio officers: part II

For illustration we will follow a radio officer through a routine departure. His ship, *SS Valiant*, is a tanker making a transit from the port of Houston, Texas to the port of New York, New York. This trip normally requires a little over five days. Our radio officer, "Sparks," is a conservative, thorough individual. Often this radio officer's meticulous logkeeping goes beyond the absolute minimum regulation compliance. By being overzealous, "Sparks" hopes to avoid "sloppiness" on essentials. As is the custom, our radio officer is on board the vessel one hour before posted sailing time. Since the *SS Valiant* is a tanker alongside the terminal, transmitter testing is not permitted. However, the other items in the pre-departure routine can be checked and logged. This pre-departure testing is neatly typed in the log and signed with the testing time. The log resembles the following:

> *4-25-75*
> *1400GMT — Pre-departure tests, Houston terminal. Main and emergency receivers work properly; B battery voltage 88 V dc under load; ship's line 118 V ac; emergency battery specific gravity 1278, batteries on continuous trickle charge of proper polarity; auto-alarm checks OK — keys after 4 spaced dashes; alarm keyer functioning normal; speaking tube communications to the bridge operable; radio room emergency lights burning normally; antennas visually checked and apparently in good order. Transmitters will be tested away from dock and radiation noted (antenna current). Radio room clock checked against WWV, 3 seconds fast/corrected. All publications and required spares on board. Tester . . . (signed)*

Once the vessel is cleared of the dock, main, emergency and lifeboat transmitters will be tested. The main transmitter will generally put twelve or so rf Amperes into the main antenna; the emergency, approximately three to four rf Amps.

Since it is several hours to the sea buoy (departure point for the sea passage), the radio officer is free of watch standing duties. Sea watches in the radio room are from sea buoy to sea buoy. Some companies require watch standing on long river transits. Whatever is in the contract will be implemented. "Sparks" will copy a weather broadcast from Galveston radio, KLC, at 1730 GMT. This will contain Gulf of Mexico weather data. Radio officers endeavor to copy weather "ahead" so the captain can be made aware of wind and sea conditions. This information enables the master to plan the most direct and safest routes; it also allows for more accurate estimated time of arrival (ETA) messages.

At 1900 GMT the ship drops the pilot and takes departure. The radio officer begins watch standing. The log is signed noting that a listening watch on 500 kHz is in progress. Every fifteen minutes a log entry is made of noted exchanges which occurred during that period. Silent periods (15-18 and 45-48 minutes past each hour are designated quiet listening segments for any distress signals) are logged as having been observed and as to whether or not signals were copied. At times the circuit will be quiet with no exchanges occurring during the fifteen minute segment — this fact is so logged. Under a plexiglas on the operating position are schedules of traffic lists, weather and hydrographic bulletins, station frequencies and other pertinent data. These schedules are kept when applicable. From experience "Sparks" knows that the bulk of company traffic is handled through Port Arthur radio, station WPA. By following WPA's schedules very closely, messages are often received minutes after they are filed.

As the ship gets under way, the captain will have time to prepare the routine departure messages and reports. These are then given to the radio officer who will process them. This involves counting words, noting filing time and date, proper addresses, etc. The radio officer then transmits the messages to the appropriate station(s). Once cleared, the messages are typed on formal cablegram blanks and filed for end of month processing. The master is given the original copy. One copy is filed for the company to receive, and another copy is sent to the radio agency for abstracting (computation of charges).

Suppertime comes and goes. After a brief recreation chess match with one of the off duty mates, "Sparks" is ready for the evening watch. Weather is again copied updating the earlier report. Traffic lists are checked for close of business day messages which often are filed. The log is kept current. At 9 pm ship's time the watch ends. Our radio officer sets the auto-alarm. This fact is noted and the log is signed out.

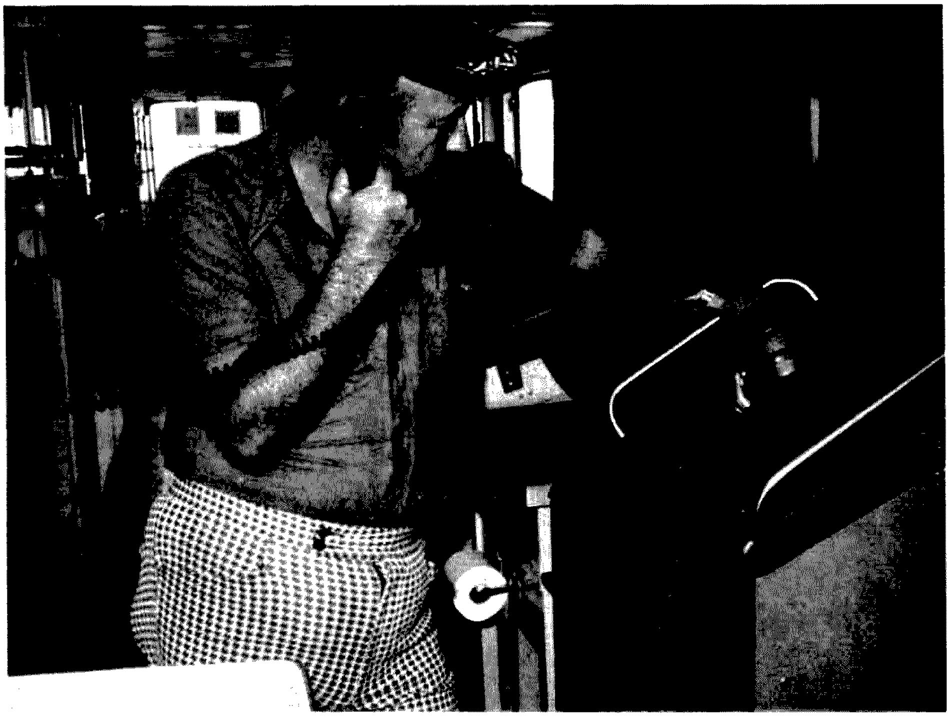
This ebb and flow of routine matters allows the voyage to New York to pass quickly. The radio officer may be asked to check the radar or loran or DF, minor problems may develop in one of the receivers or transmitters, or orders may be received to proceed abruptly to some other destination. Each day brings its own challenges. After eighty days on the tanker, the radio officer will be relieved for forty-five days paid vacation. This time will be used to rest up from the sea routine. Perhaps "Sparks" has some budding business interests – a farm or rental properties to attend, or some recreational development. Some radio officers simply enjoy spending a large amount of time off with the family. Whatever the preoccupation, the time passes once again and "Sparks" will be notified to report back to the same or some other vessel. The radio officer will bring his or her growing electronic knowledge and experience to bear once again on any situation the next eighty days on shipboard will bring.

Photo courtesy of Gene D. Legler, Editor, *Exxon Fleet News*, Exxon Company, U.S.A., Houston TX.

Traffic Handling

Traffic, messages sent and received, take up a good portion of a radio officer's watch time. Commercial operators have always prided themselves in their ability to handle a large volume of traffic with dispatch. The commercial operator is trained to copy with one hundred percent accuracy exactly what he hears. Most operators become proficient enough with the typewriter to almost sign their names. When one considers the high costs of operating oceangoing vessels today, one appreciates the need for accuracy in messages. Costly cargo operations, tugboat standby time, or overtime for repair people can all be the direct result of inaccuracies in cables. That is one reason every commercial operator carefully checks a received message for word count before acknowledging (QSLing) it.

The ability of commercial operators to handle traffic well is due in part to standard operating techniques. Crisp, snappy Morse exchanges with no superfluous sending are the key to professional radio operating. For those not familiar with commercial procedures a contact will be briefly outlined. Ship station KAVQ wants to send traffic to coast station WPA, Port Arthur radio, using the 12 MHz band. The radio officer tunes his receiver to WPA's marker frequency (12840) and then calls on KAVQ's calling frequency (duplex operation). Station WPA is constantly scanning the calling band. Rigid FCC rules must be adhered to regarding length and spacing of calls. WPA hears KAVQ calling and communication is established. The ship station will change (QSS) to the FCC assigned working frequency after advising WPA which this is so Port Arthur can tune its receiver to KAVQ's working wave. Once QSS is accomplished and communication established, KAVQ asks WPA, "QRV?" (Are you ready to copy?) WPA sends K and KAVQ responds as follows (a



"dummy" message for illustration):

```
- · - · -    (BEGINNING SIGNAL)
MSG NR 1 SS STAR CK 8 16 1423GMT BT
KESTAR NEW YORK BT
ETA 18TH 0500 REQUIRE 2000 BUNKERS BT
AR
```

Examining this message we find the following:

Preamble: Consisting of message class (MSG), number (1), word check (8), date (16), and time (1423 GMT) of filing. A $\overline{\text{BT}}$ is sent signifying to the receiving operator to throw the carriage of the typewriter as a break is needed.

Address: This is usually a cable address such as "Keystar" followed by the name of the city in which addressee is located (New York). Again a $\overline{\text{BT}}$ signifies a break.

Text: The actual message itself. Followed by $\overline{\text{BT}}$.

Signature: Not always contained in cables.

In counting words, each word in the address, text, and signature is counted. As an operating aid the signal $\overline{\text{AR}}$ is sent at the end either of the text after $\overline{\text{BT}}$ or after the signature to indicate the end of this particular message. If another message is to follow, the operator will simply send the class designation after the $\overline{\text{AR}}$. For example, after $\overline{\text{AR}}$ the radio officer will send NRT to indicate another message of the NRT type will be sent. The coast station will acknowledge with a "QSL" and indicate a "K" or "QRV" to let the sending operator know the next message can be sent.

When the coastal station has a message the same format is followed. In place of the ship's name in the preamble will appear the city of message origination. Rather than a cable address, the message will be addressed to the vessel; usually the master's title will precede the vessel's name. Thus:

```
MSG NR 1 NEW YORK CK 7 18 2200GMT BT
MASTER, SS STAR BT
BUNKERS ACKNOWLEDGED CALL OFFICE SOONEST BT
AR
```

Traffic handling facility is acquired through practice. Time spent listening to top professional commercial operators at the busier marine stations (WCC, WSL, JCS, etc.) is a good investment. With experience the beginning radio officer will appreciate the skill involved in apparently simple, efficient exchanges of Morse. The master operator sends not one unnecessary dot or dash.

Mechanics of counting words (doubles, triples, etc.), assigning prefixes, and routing messages is acquired through usage and imitation of accepted commercial practices. ITT Mackay Marine has a comprehensive "Radio Officer Manual" which details message processing as well as a wealth of other information. All ITT Mackay contract ships have a copy of this text. RCA has a similar publication on its contract vessels. With practice and attentive listening, a new radio officer will soon become proficient in traffic handling.

Standard Shipboard Publications for the Radio Officer

All licensed shipboard installations are required to have on file the following publications in order to meet with full FCC compliance. Required documents are included in the list.

1. Valid station license.
2. Valid operator license.
3. Required station logs.
4. Alphabetical list of call-signs of stations used by the maritime mobile service – current edition.
5. List of ship stations – current edition.
6. List of coast stations – current edition.
7. List of radiodetermination and special service stations.
8. Manual for use by the maritime mobile service – ITU Geneva.
9. Part 83 of FCC Rules and Regulations.

With the above reference publications, the ship may go any place in the world and the radio officer will be able to locate appropriate coastal stations, their schedules, tariffs, routings, time ticks, and other needed data. A few explanatory paragraphs will be given regarding the publications and documents.

1 and 2. A valid station license is extremely important. The radio officer should inform the master if the license is nearing expiration. Heavy penalties are incurred for invalid licenses. It is assumed the radio officer's licenses are current and posted.

3. Station logs as well as other required stationery are usually supplied by the contracting agency. Message blanks, requisition forms, and work orders are all supplied by the husbanding radio contract company. Other normal stationery items (pens, pencils, notepads, etc.) are supplied by the particular steamship company. The radio officer is responsible for keeping the inventory at reasonable levels: usually six months of supplies are considered adequate.

4. A quick reference manual for identifying ships or coastal stations from their assigned call letters. New editions are constantly being published to keep the radio officer abreast of changes.

5. This is a more elaborate manual (over 500 pages) listing ships alphabetically by name. Pertinent data is given for each ship: type of equipment (telephone, telegraph, etc.), hours of service, ship classification and other useful information concerning the communications ability of the vessel. The present edition contains information on over 52,000 stations.

6. Perhaps the most

important and useful publication. It gives the radio officer a tool which can direct him or her to unfamiliar ports of call. The list contains pertinent information on coastal maritime stations around the world. It is republished every two years; supplements are issued every six months. This manual contains three parts: a. Alphabetical index of coast stations; b. Full particulars of each station — frequencies, operating times, traffic listings, particular communication procedures; c. An annex which gives inland telegraph rates, tariffs, and other monetary information. Once a radio knows the vessel's itinerary, this publication can be consulted and schedules planned.

7. The manual of radiodetermination and special services can be considered the next in relative importance. Part A of it gives an alphabetical index of all stations listed. Part B gives the particulars of these stations. The most useful of these are the areas of radiodetermination (direction bearing stations), time signal information for accurately setting of chronometers, and stations dispensing medical advice. The publication is complete and comprehensive. The present edition contains 750 pages.

8 and 9. These publications contain regulatory matter. The first has chapters on internationally agreed regulations and procedures; the second contains the Federal Communications Commission's regulations for the Maritime Mobile Service. These are excellent operating aids.

Besides the above publications, each radio room will have on file the various operating and technical manuals covering the electronic equipment installed. These represent invaluable service tools and maintenance aids. They give prints, upkeep information, parts nomenclature, troubleshooting procedures, and correct operating techniques. Almost any repair situation can be solved through judiciously studying the manual. If an exact remedy cannot be found, the general area of fault can usually be determined — information helpful in ordering shore repairs.

Basic Electronic Maintenance

Newly documented radio officers channel their efforts at first to learning the "radio operating" aspect of the profession. However, it will soon become evident that more is expected of a ship's radio officer. As indicated in other sections, the actual operation of the radio station becomes routine with experience. A radio officer's other responsibility is the proper maintenance of the station as well as other electronic equipment within his or her ken. In addition to the receivers, transmitters, power supplies and chargers located in the radio room, a competent sparks also will keep in proper operating order the radars, loran, direction finder, recreation shortwave receivers, and televisions on board the vessel. A person who can handle this varied array of equipment, keep shoreside repair bills to a minimum, and obtain maximum performance from the communication and navigation gear is much sought after by companies and captains alike. This section will delve into some very basic concepts of shipboard electronic maintenance. The subject is an exhaustive topic and spans the life and career of each radio officer.

All electronic equipment contains normally a combination of electronic circuitry and mechanical movements (dials, drives, relays, multicontact switches, etc.). While this apparatus is designed to operate in a vigorous salt air environment, the pounding of the ship, exposure to heavy humidity, and operation by many individuals all take their toll on equipment performance. One simple, basic preventative maintenance program is to keep the equipment clean of salt and corrosion. Wiping surfaces, cleaning and lubricating contacts, burnishing pitted relays, lightly greasing cams, gears, chain drives, reseating tubes and crystals to remove any corrosion from forming on pins — all these elementary procedures will contribute to optimum operation of electronic gear.

Electronic apparatus employing high powered electron tubes can be disabled through a simple filament break in one of the high temperature tubes. This is a basic defect to investigate when this type of equipment fails. Power transistors are subject to the same type of thermal punishment and often open or short under such pressures.

Electronic troubleshooting requires organized logical thinking. No matter how complex the unit to be serviced, it contains the workings of the three basic electronic circuits: rectifiers, amplifiers and oscillators. If a person has a sound grasp of the operation of these circuits, the defective element (resistor, coil, capacitor) can often be pinpointed through simple voltage and resistance measurements. The prints contained in the manuals offer clues as to what proper readings should be found. Any wide deviation from suggested call-outs in an electronic print should alert the radio officer to seek reasons for the deviation; often the "reasons" will be the faulty component located.

As with radio operating, one becomes proficient in basic maintenance and troubleshooting of gear with experience. Certain faults will occur over and over. Eventually symptoms will be immediately recognized and the fault will be rapidly repaired. Many radio officers work at one time or another at repair depots ashore. These are either electronic maintenance companies, television repair facilities or two-way radio repair terminals. This shoreside experience is valuable. Techniques are developed which speed servicing. Much can be learned from senior technicians with many years of experience. These people are usually more than willing to share their experiences with beginners.

It is well to note at this point that radio officers receive base wages for the eight hours (normally) watch standing. All repair/maintenance work is additional compensation earned outside watch hours. Shipping companies have found even with the overtime paid they still are ahead economically. Large service companies of necessity charge high rates. They may have to travel long distances, wait hours for delayed arrivals, and in general contend with costly overhead expenses.

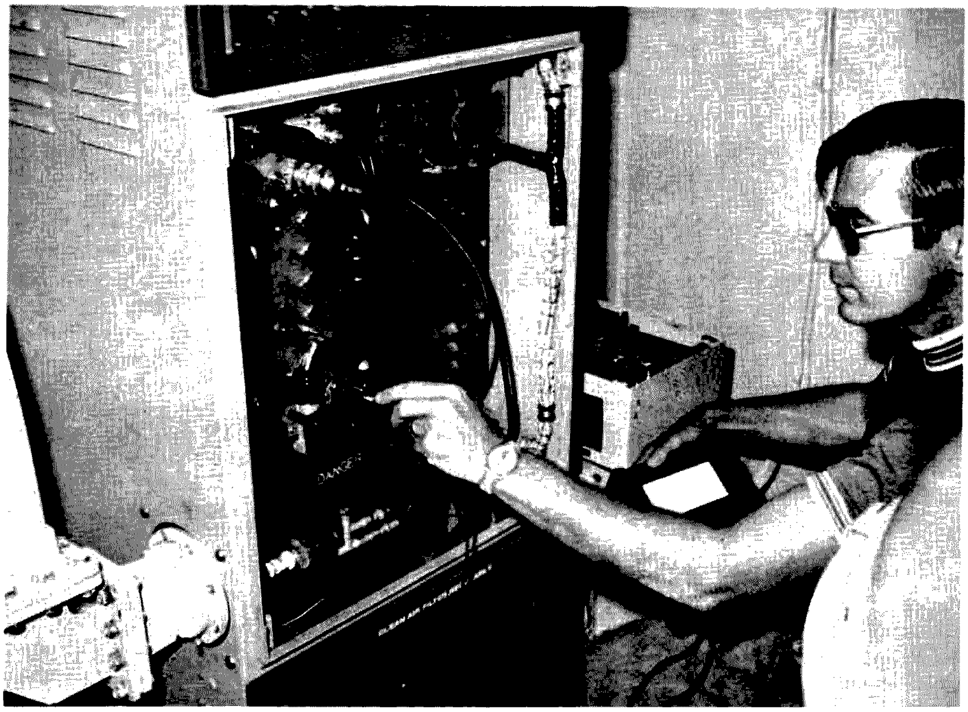
With advances in modern day technology, satellite communication capabilities, and automated telex (unattended) terminals installed aboard ships, it is very possible that international and national regulations will be amended some day possibly eliminating the traditional role of radio officer as presently known. However, it is the consensus of all those knowledgeable in shipboard manning policies that a place will always be available on a vessel's articles for some type of "electronic officer," a person (male or female) who can cope with sophisticated equipment and effect repairs necessary to keeping communications "alive" between the vessel and shore. No one will venture how far into the future this situation will materialize. However, the technology is available today. Regulatory agencies, however, require lengthy periods to legislate major changes. The person who keeps aware of advances in communication electronics, broadens his or her electronic expertise

through study and application, and brings a common sense practical trouble-shooting approach to repair situations has taken positive steps to enhance his or her worth to the company and keep the job secure.

Goals

It is hoped that the reader has found helpful information in these pages. I have attempted to bring together material aimed at positive means of joining the ranks of radio officers. As in many narrow specialties, it is difficult to "break in" the profession of radio officer. The rewards as hinted are ample for those who pursue the necessary courses of action to qualify. The opportunities are open to both men and women. Foreign flag vessels have employed female radio officers for years. Many of these women, in addition to sending beautiful commercial CW Morse, are competent electronic technicians.

As in any profession one encounters the excellent, the mediocre, and the incompetent. Anyone seriously endeavoring to embark on a seagoing career as a radio officer is wholeheartedly encouraged to strive for excellence in performance. Conscious awareness of sending good CW, meticulous log-keeping, faithful performance of required tests, error-less copies of messages, weather reports, hydrographic bulletins — all these mark the truly professional radio officer. After becoming settled in commercial radio operating, further study to acquire the radar endorsement on one's license will enable the holder to perform more complex maintenance on these units. Passing the higher code test after a full year's service is acquired will grant the radio officer the first class radiotelegraph license, the apex in certification. Proficiency in repair and maintenance of electronic equipment will bring additional financial remuneration as well as a gratifying sense of technical achievement.



A sincere "73" and best of luck. May your efforts toward becoming a Merchant Marine radio officer be crowned with success. ■

Stations use their medium wave through twelve megahertz bands adding higher frequencies when propagation is open.

APPENDIX B

Employment Sources

There are two national maritime radio officer unions. Each of these unions has branch offices in all major port cities of the United States as well as keeping headquarters located in New York City.

The first of these two unions is the *American Radio Association*, an AFL-CIO affliate. This union has numerous companies under contract: Lykes Brothers Steamship Company, Keystone Tanker Company, and American Export Lines, to mention only a few. Additional information can be acquired from either the headquarters in New York or any of the many branch offices located around the country. A person shipping via a union hall usually registers at the office nearest his or her home as transportation reimbursement will be calculated to and from this point.

Of interest to radio officer aspirants is the Free Press which the American Radio Association (ARA) sponsors each Sunday at 1818 GMT. ITT Mackay station WSL, Amagansette, N.Y., transmits this weekly Press on frequencies (in kilohertz) 6414, 8514, 13078, 17021 and 22485. Items in this Press concern maritime happenings of the past week. Special interest is shown in this press when new contracts are pending; complete details are generally sent.

The second national radio officer union is named, appropriately enough, *Radio Officer's Union.* This union also has branch offices in major port cities. Companies which utilize men from the

ROU, such as Mobil Oil, Delta Line, and many others, depend upon the union to recruit enough members to fill any vacancies which occur.

Government agencies responsible for crewing of specialized vessels represent an excellent source of employment. United States Coast and Geodetic Survey vessels hire qualified civilians. These ships make fine berths for a person to enter commercial radio operating. One may even opt to remain as a civil service employee as a career. Generally the pay scale on such vessels is lower than on other commercial ships. Thus a large turnover in manpower is ordinarily experienced. Military Sealife Agency (MSA), with offices in New York and San Francisco, concentrates its efforts using civilian crews to operate vessels which carry exclusively military cargo items. The Corps of Army Engineers occasionally requires radio officer personnel on its large offshore dredges and supply boats.

Private research and oceanographic companies generally hire radio officers for upcoming projects. Herein lies potential employment leading to the six months' endorsement, as many of the research vessels are voluntarily equipped. Texas A & M University operates one such vessel. The Woods Hole, Mass. project has its project ship. Inquiry can be made of oil consulting firms which operate survey type boats requiring the services of radio officers.

Besides the national unions for radio officer registration, many smaller steamship and tanker companies hire individuals without union affiliation. Most of these "independent" companies do have "independent" or company-organized unions with membership optional. Such companies are Hess Oil, Sabine Tankers, Exxon U.S.A. Tankers, Sun Oil, and many others. Inquiries of one of these companies will generally glean "leads" to other companies who hire independent of union affiliation. Time spent researching the yellow pages of the phone directory of any large port city will lead to positive and plentiful potential employment sources.

APPENDIX C
Types of Equipment

Any licensed United States Maritime Mobile Radio Station is required to have certain minimum equipment to satisfy compliance with FCC regulations. Compulsorily equipped vessels generally will have the following electronic items in the radio room:

Reserve Receiver: This can be operated from battery supply voltages in an emergency. Frequencies covered by this receiver must be in the 15 kHz through the 650 kHz spectrum. Most older installations use superrengenerative receiver circuitry. More recent installations use low power consuming transistorized heterodyne principles.

Main Receiver: This is generally an extremely well built double or triple conversion superheterodyne circuitry receiver which operates off the ship's mains. Modern RCA and ITT Mackay receivers cover 80 kHz through 30 MHz in numerous bands. For convenience, each band usually tunes a 500 kHz segment of the band desired at a time. The RCA 8516 model is one example of a modern shipboard general coverage receiver. All modes (AM, CW, SSB) of reception are included as well as a variable bandwidth to help copy signals on crowded bands. The ITT Mackay 3010C has become a standard of excellence for shipboard receivers. It is rugged, stable, versatile and costly. Made to rigid commercial specifications, this receiver gives years of service with minimum maintenance. Terminology varies regarding the "reserve" and "main" receiver concepts.

Main Transmitter: These installations cover 400 through 535 kHz and range in output power from 200 Watts to a thousand. The more common main transmitters put 250 to 500 Watts into the antenna. Both A1 and A2 emission modes are contained in the units. Output configurations of these transmitters enable a wide variety of antenna types to be used. Most popular is the longwire and vertical (top hat) loaded antennas.

High Frequency Transmitter: These installations are the units which usually get the "communicating" done over long distances. It is quite normal to consistently "work" home stations halfway around the world. These HF transmitters generally cover 2 MH through 24 MHz. Crystal controlled oscillators eliminate off frequency excursions. Generally a ship will have two calling frequencies and two working frequencies in each of the harmonically related marine bands of 2, 4, 6, 8, 12, 16, and 22 MHz. Thus a potentially large number of channels are available for needed communications. Emission of the HF transmitters is A1; however, some units combine AM telephone operation permitting A3 operation in allocated bands. The FCC has legislated that no amplitude modulation be permitted after 1977. Ships will then be required to use the suppressed carrier single sideband transmission mode. Many ships today are SSB equipped for its excellent communication ability.

Reserve Transmitter: Like the reserve receiver, this must be capable of operating off emergency battery voltage. These units cover 350-515 kHz using A2 emission with output power in the 50 Watt range. Versatile antenna networks allow matching of even random wire lengths should critical situations require this.

Auto-Alarm: The purpose of this device is to stand a watch on the distress frequency when the radio officer is unable to either because he is off cuty or because of other extenuating circumstances. The international alarm signal consists of a series of dashes four seconds in length, separated by spaces having a duration of one second. Auto-alarms designed to meet FCC specifications are arranged to actuate an audible alert (bell) when four correct dashes and spaces have been received. Modern alarms utilize transistor circuitry achieving high reliability. Older alarms, through a system of stepping relays, require more maintenance to keep the mechanical system operative. The auto-alarm receiver covers 492 to 508 kHz. Nominal standard signal is of 50 microvolts.

Auto-Alarm Keyer: This unit is operated in conjunction with the main transmitter and will send out, mechanically, the appropriate alarm actuating signals. Standard procedure is to send the keyer signal for a minute followed by the SOS message.

Battery Charger(s): The radio officer is responsible for keeping the emergency batteries in a good state of charge (specific gravity of 1278 or so). Battery charging devices are part of most consoled equipment which can be manually or automatically operated.

That is the very basic radio equipment found on compulsorily fitted vessels. More elaborate installations will include VHF/SSB/AM radiotelephones, facsimile receivers and machines, radioteletype equipment, and perhaps satellite communications facilities.

Bridges of vessels are fitted with sundry electronic devices. Loran, omega receivers, Decca navigator gear, ten and three centimeter radars, collision avoidance computer systems, autopiloting systems, and remote radiotelephone installations

are some of the more complex items found on modern day vessels.

APPENDIX D
Antennas

A moot question often develops among radio engineers: What is more important, a higher powered transmitting system or a redesigning of the antenna system? This answer will not completely satisfy both parties but is sufficient for discussion purposes here: The better the radiating facilities connected to a transmitter, the more economical and efficient use is made of the power required to produce increased output. Thus, shipboard antennas are very important devices which require special consideration.

Earlier shipboard radio history details that simple longwire antennas worked efficiently for the medium frequencies being generated. Even today the best radiator for the 400-500 kHz band is a good longwire stretched as far as possible between two points aboard the vessel. Ships with such longwires work coastal stations at far greater distances then sister ships equipped with verticals. However, once high frequency transmission became commonplace, the vertical antenna proved to be an excellent device for shipboard installation. Rugged and efficient, a vertical cut for the 8 MHz band and properly loaded for others can effect around the world communications when linked to a transmitter in the 200-500 Watt output class. In special class vessels where longwires cannot be located, the verticals are coil loaded to resonate on the lower frequencies. This is inefficient and the range of communication diminishes. Most ships will have a combination of longwire(s) and vertical antennas to take advantage of the inherent characteristics of each.

Watch DX with a Spectrum Analyzer

-- seeing is believing

If you've ever seen or used a spectrum analyzer, you know how valuable they are. After calling CQ you can see the signals replying without touching the receiver. When chasing DX you can see the weak signal before hearing it and therefore tune more carefully. An analyzer is useful for finding clear spots in a crowded band or weak signals in a quiet band.

Connecting the analyzer to your receiver is no problem. The analyzer input signal is obtained from the plate of the first mixer stage of the receiver. The frequency response at this point is quite broad and enables the analyzer to view as much as 100 kHz of the band.

Unfortunately, some amateur and general coverage receivers change mixer output frequencies for different bands (as shown in Fig. 1 for the Hammarlund HQ-180).

With this type of receiver, either 2 spectrum analyzers must be used, or one analyzer to cover only a portion of the receiver tuning range, or one analyzer with an external converter. With cash output already exceeding income, the XYL was not exactly happy about buying another analyzer. Having used the analyzer on the high bands, I was lost without it on the low bands. I therefore decided to build an external converter to convert the low band i-f up to the high band i-f required by the analyzer (as shown in Fig. 2).

The oscillator is not critical, but should be crystal controlled for stability. However, I was reluctant to spend any money at all, and the receiver just happens to have a crystal oscillator which isn't doing anything when the receiver is tuned to the low bands. With the addition of a ½ Watt resistor, I now have my oscillator, and if the mixer is passive, no external power supply is required. Granted, I now have a "birdie" at 2.58 MHz, but so what. It's not in an amateur band or a broadcast band and there isn't anything else.

The completed circuit is shown in Fig. 3. It's simple, it works, and best of all, it's cheap. Resale value is not noticeably affected so long as the extra 22 kΩ resistor is removed prior to sale.

Construction was not critical, except keeping the input away from the output. The diodes can be almost any decent switching type, but should be germanium (hot carrier diodes might be an improvement). The input transformer is normally used as an FM descriminator and is therefore quite broad-banded. The output transformer primaries should be balanced. ■

DXing with a Weather Map

-- a new 6m DX technique

Since I read all the propagation reports, I decided it was about time to chime in my two cents worth (15 years worth to be more precise). This is an article on the propagation of radio waves – 6 meter radio waves to be exact. As anyone can tell by my past VHF articles, I am addicted to that portion of our bands.

There is one BIG factor in 6 meter propagation many seem to overlook except for some of its groundwave effects – WEATHER!

Nearly all large newspapers cover the only information you really need. I'm referring to the little map that shows all the little high and low pressure cells floating around and the fronts are shown, too. If you can copy the weather satellites, all the better, but at least make sure what time your newspaper map was drawn up for, as there is a lag from weather bureau to news desk, to press, to you. You will need to adjust for that difference, as weather is everchanging.

The trick for single hop DX (I know, E layer and all that jazz be darned) for us has been to find a low pressure (storm type – mucho electrons excited) cell about halfway between us and where we want to go. If you can draw a straight line (allowing for the Earth's curvature) from you to the desired destination, and hit the "edge" (not middle) of one of these cells, you are home like a bandit. More than 50% of my DX work has occurred on a *dead* band! There is much pleasure in this, too, until everybody else wakes up, since your contacts can be many minutes long and quite rewarding – not 5-9-9 contest style.

In order to explain the edge of the storm cell theory, and since no one (including me) seems to ever remember it by the direction of wind circulation around the cell, let's take a storm cell (low) to your West. Aim to go "under" it as it appears on the map. Example: I am in Indiana, target is California, and cell is right on a line from Indianapolis to San Francisco and about halfway between. Aim on the Los Angeles side, not the upper or Sacramento side. Reverse this and go "over" storms to your East, left of storms to your North, and right of storms to your South. All this is with reference to a map laid before you with the North direction to the top, which is the normal.

I neither know precisely why this works, nor why the other side of the low cell doesn't work – nor does either side of a high pressure cell regardless of its size or intensity! I assume it has more to do with the electrical charge and intensity than the barometric pressure itself.

I sincerely would appreciate hearing any and all reports of success or failure using this method; as for me it has proven almost 90% effective. Give it a chance to work before you panic and scream. Also, anyone who believes he can explain why it works is welcome to do so. I do things because they work and then figure out why. Just a simple explanation will do. Random chance for such an occurrence is extremely small compared to our success.

Thank you all for the SASEs on past articles – it does assure you of a speedier reply – usually one day turn around unless you totally stump me, which has happened. There were over 240 letters on the article on strobing displays, on updating counters in general and specifically the K2OAW model I started with. Forgive me please the "form" letter replies, but they let me answer all but one of them the same day.

Good DX, and when the low pressure cell gets very close to you with its inherent lightning – give it up for awhile or your next record mileage may be a QSL card from the heavens above! ■

Social Events

DALLAS TX
NOV 5-7

The First Southwest Vintage Radio & Phonograph Convention will be sponsored by the Southwest Vintage Radio & Phonograph Society on the 5th, 6th and 7th of November at the Ramada Inn-Dallas East in Dallas, Texas. Planned activities include forums on collecting of antique and vintage radios, restoration of antique radios, classic radios (McMurdo-Silver/Scott), antique phonographs, and general Q&A. The usual banquet, swap sessions, and an auction will also be held. Of special interest will be a contest of various equipment submitted by convention registrants. Three prizes will be awarded in each division. In addition a "Best-of-Show" award will also be made. For more information and a pre-registration packet, please contact Convention SVRPS, PO Box 19406, Dallas TX 75219.

McAFEE NJ
NOV 13-14

The 1976 Hudson Division Convention will be held November 13-14, 1976 at the Great Gorge Resort Hotel in McAfee, New Jersey. There will be ARRL and FCC forums, large indoor exhibit area with 40 booths, giant outdoor flea market, super raffle, free gifts, special features, indoor swimming, game room, and much more. Registration: advance $3, at door $4. For hotel registration: Al Piddington WA2FAK, 4 Acorn Drive, East Northport NY 11731.

LIVINGSTON NJ
DEC 3

The Livingston Amateur Radio Club will hold its second annual electronic flea market on Friday, December 3, at 7:30 pm at the Livingston Memorial Recreation Building. For further info, contact Jeff Gehl WN2AXL, (201)-267-0280.

BROOKLYN NY
DEC 19

The Kings County Repeater Association will hold an indoor flea market on Sunday, December 19, 1976, from 9 am to 4 pm. Located at 910 Union Street, Brooklyn NY (at Grand Army Plaza). Sellers $3.00, buyers $1, children free. Refreshments available. Talk-in on 146.43 and 146.52.

DAVENPORT IA
FEB 27

The annual Davenport Radio Amateur Club Hamfest will be held Sunday, February 27, 1977 at the Masonic Temple in Davenport, Iowa. Admission is $1.50 advance – $2.00 at the door. Talk-in on 28/88 and 52. Refreshments and tables are available. For info and tickets send SASE to Dick Lane WAØGXC, 116 Park Avenue, So. Eldridge IA 52748.

FORT WALTON BEACH FL
MAR 20

The Fort Walton Beach Swapfest will be held Sunday, March 20, 1977. For further information contact Playground Amateur Radio Club, PO Box 873, Fort Walton Beach FL 32548.

I/O EDITORIAL

from page 71

would go almost mad to be around that much in goodies. 8080s? Oh yes, here is a carton of several thousand. Memory chips? They're over there in

that stack of cartons. One of Godbout's most popular items is a 4K memory board, and we got a promise from Reo Pratt for an article on it for *Kilobyte*.

Bill and Reo drove us over to see George Morrow . . . an incredible genius. He was hard at work on a whole bunch of projects . . . the Godbout PACE computer system (working just fine and ready for production) . . . a front panel for the Altair and Imsai with a fantastic operating system built into it . . . and a bunch of other projects. George promised articles on the PACE, on his front panel, on stopping a computer, on his secret prototyping system. Now if we can only get him to stop building long enough to write!

Bill, Reo, George, Sherry and I got in Bill's plane and flew out to Santa Rosa for dinner. I spent most of the time rag chewing on 2m with my HT. Bill had bought the plane up here in New Hampshire last spring and taken it back to Oakland. They originally tried to get me to buy the plane (it was a very good deal), but I am too careless a pilot and if I started flying again I'd kill myself for sure. I sold my last plane when I needed money to put out the first issue of *73* . . . in 1960. I had a lot of adventures while I had my plane.

Down in L.A. we visited Dennis Brown of Wave Mate. This is the wire wrapped computer . . . and it is a bit more expensive than most of the others so business wasn't quite as hectic as for some. I suspect that once Dennis gets his ideas across there will be a lot more enthusiasm for both wire wrapping and for the Wave Mate. There will be some articles by him on both wire wrapping and on the design concepts at the Wave Mate. There may be a Wave Mate in your future . . . watch out.

John French of The Computer Mart in Orange has been doing fantastically with high Lear-Siegler terminals and was putting the finishing touches on a 16-bit computer system which will be introduced shortly. Naturally, we got a promise of an article on it for *Kilobyte*. Just what the computer hobbyist reaction to the coming 16-bit systems will be is quite a question. They probably don't need the speed and computing ability of such a machine, but I'll bet they will go for it anyway.

My next stop was in Salt Lake to see how Sphere was doing. They've been having quite a bit of trouble . . . in part due to a credibility gap on promised software . . . partly due to parts problems . . . documentation delays . . . etc. The new president, with whom I had an appointment, was not available. Doug Hancy gave us a tour of the building and promised that a system for our lab would be shipped immediately.

Next month: on to Albuquerque and the Mighty MITS Machine!

NEW AND BETTER CHIPS

There is a lot of excitement over the Zilog Z-80 microprocessor chip. It is an advanced version of the Intel 8080 . . . much more flexible. I view this with very mixed emotions . . . on the one side I'm enthused about being able to put aside my nice $650 CPU with the 8080 and put in a new Z-80 CPU which will probably run another $650 or so. I'll overlook the fact that I've barely been able to get the old computer system working long enough to do much with it . . . certainly not long enough to develop a large number of programs.

I suspect that the Z-80 means that much of the small computer industry is going back to square one as far as programming is concerned. While it is nice that the Z-80 will work with the 8080 programs (not completely, I understand . . . but for the most part), I also understand that no serious programmer would ever put up with using 8080 programs on the Z-80 . . . it isn't efficient. No, they'll go back and write new compilers for BASIC . . . and that might take as long as last time.

The Altair 8800 first came out in January, 1975. Their BASIC compiler was debugged and out about a year later . . . and we are still waiting for much in the way of application programs for the system. The fact is that it takes a long time to write programs. The 6800 came out along in late 1975 and, as far as I know, there

is not yet a BASIC compiler available for it that is full sized. There are a couple for Tiny BASIC or Micro-BASIC . . . and others are to be ready soon. There is less than that for the other systems which have come later.

So here we go back again! And when the Z-80 comes along next January, will we do another memory dump and start still again? Or will it be the Intel 8888 that gets everyone all excited next year . . . or the year after? There is much to be said for sticking with the good old 8080 and working out programs so that we can use it.

Space is available for conflicting viewpoints, as they say on TV.

NO WAY TO TURN

The old "tube" hams are getting very nervous. The rash of articles in *73* bringing us all up to speed on modern technology . . . the large scale integrated circuit and its main result, the microprocessor, has sent some into shock . . . others to the midnight oil to try and catch up. The "I just don't want to know about it" crowd (3999 kHz, e.g.) thought they had an out . . . until their last inner sanctum of protection against the onrush of progress dumped on them with a series of articles on . . . microprocessors!

Other than canceling subscriptions to everything but *CQ*, there *is* no way out. The initial reaction was of utter panic . . . computers are *not* any part of amateur radio and they will *have* to go away . . . right?

Speaking of *CQ* . . . has anyone seen it on the newsstands anywhere? It used to be sold by newsstands, but I haven't seen it in a couple of years anywhere. I think *73* is the *only* ham magazine being sold on newsstands these days.

If you happen to run into old-timers suffering from future shock and who want to get into at least a speaking acquaintance with microcomputers, the new *73* book "Hobby Computers Are Here!" is the only book out which will help make the transition relatively painless. $4.95 from the *73* Radio Bookshop. Engineers may get some value out of the *HR* series of reprints from a scientific journal on microprocessors. So far, about 90%+ of the original material on the subject has been published in *73* . . . shades of the old FM days seven years ago.

WILL KILOBYTE ROB I/O?

It appears as if *Kilobyte* is going to be a lot more software- and systems-oriented than the I/O section of *73*, so I expect that I/O will be carrying on. We've covered a lot of the computer fundamentals in *73* already, but we still have more to go. And we surely are going to have a lot of ham applications of computers in *73*. Hopefully, once the basics of the field are published in *73*, we won't have to go back over them.

Authors with ham applications for computers should run, not walk, to their typewriters.

ATLANTA 1977

The Atlanta Hamfest is being expanded this coming year to include a Computerfest. The Hamfest will be centered on Saturday, June 18th and the Computerfest on Sunday, June 19th. This will be the big hamfest and computerfest for the southeast for 1977, so plan your vacations accordingly.

Atlanta is a great city for something like this since there is so much entertainment for the family . . . they don't have to stand around whining while you take a close look at the latest equipment. Stone Mountain will keep them occupied for at least a day . . . they'll enjoy the excitement of a ride on the railroad around the mountain. Then there is Underground Atlanta . . . complete with a computer which will print out your portrait on a Teletype machine! Atlanta has a lot to offer.

In addition to about 80 exhibits by ham dealers and manufacturers, there are expected to be about 50 or so by computer firms . . . and perhaps the biggest flea market yet for both ham gear and computer equipment. You'd better make your reservations early so you'll be right in the middle of the action.

EDITORIAL BY WAYNE GREEN

from page 4

for protecting our low bands (we've already lost almost all of our VHF and UHF bands) is to get one or more teams of top-notch ham ambassadors out there to sell amateur radio to the smaller countries.

The obvious way to do this is to get the ARRL directors off their duffs, and have them reach into the League pocket and get people like Bill Eitel or Lloyd and Iris Colvin out there visiting these important countries. The League has over $1,000,000 just sitting around in cash and securities, which should be out there working for the hobby. Perhaps it is time for the members to insist that the Miser of Newington stop hoarding money for some rainy day and check the storm clouds which are brewing.

Several years ago the board of directors set aside a $100,000 slush fund for "protecting our frequencies." Money gets spent out of this fund every year, but so far no accounting of these expenditures has ever been made to the members. The hundred thou would probably do the job we need done – if it were used honestly.

So what can *you*, the ARRL member, do? You can pin down any ARRL director who shows his face at your club or at a hamfest and insist on getting an accounting of *your* money. Insist that he tell you exactly how that hundred thou has been used in the past, or vote him out of office. Don't blame the officials too much . . . the money was there and they thought there would be no accounting to the members for it, so they did just what you might expect.

If your director levels with you about the corruption, and promises not only to end it but to see that something is done immediately in the way of serious WARC (ITU) preparation, then perhaps you can forgive him for being part of the coverup and elect him again.

Lloyd and Iris Colvin would be ideal ham ambassadors . . . they know the values of amateur radio to small countries . . . they've been just about everywhere in the world, and they are about as nice people as you will ever meet. Lloyd was being considered seriously for president of the League a few years back, and I think that one of the most serious mistakes the directors have made in recent times was in giving in to Huntoon and electing his crony Daniels.

We have but two years left to beat the bushes for votes among the small countries . . . are you going to let this conference go the way ARRL did the last one, when we lost 64,492 MHz out of our UHF allocated 64,495 MHz? That's right . . . we went into the last conference at the ITU and lost 99.995% of our UHF satellite frequencies. If you don't put the pressure on your director and do it right now, you could be doing great harm to one of the most valuable human resources our country – or any other country – has . . . radio amateurs. Elect directors who will break the cobwebs on the Newington purse and get us all out of this fix. Let's put some of that million bucks to work while there is still time.

IT MAY BE A FIGHT

Since Baldwin (he's running things now) permitted the board of directors of the ARRL Foundation to resign in protest rather than permit that organization to try and help with the WARC effort, it seems more than likely that he will do everything he can to prevent the directors from pursuing the same goals. I'll bet you haven't heard about *that* fiasco from your director either . . . most of them are

sitting on top of that bomb and don't know what to do about it.

Being an ARRL director may have prestige, but it offers little fun. Most of them are afraid to talk with other directors, for they never know which one will report it to Baldwin and make them suddenly "the enemy." Directors are supposed to show up at one or two meetings a year, vote unanimously yes or no, and not ask too many questions. Other than that, they have to go to club meetings and hamfests in their area and pass along the "word" from HQ. Members keep this system going by re-electing directors for years.

Perhaps it is unreasonable of me to measure the interest of a director by whether he gets *73* or not . . . but how can anyone really be in touch with things if he doesn't read *73*? I just checked, and seven of the 15 directors are *not* subscribing. If you run across Haller, Egbert, Zak, Sullivan, Thurston, Gmelin or Price, you might mention the terrible things you saw in *73* about them . . . drive them crazy.

Half of the directors are up for grabs every year, so you *can* change things if you'll take an interest. Get someone you can trust to run for the job and get him elected. There were a lot of posters at the Chicago hamfest for Don Miller W9NTP to replace Haller . . . that would be a great change. Don is the SSTV pioneer, not the DXpeditioner who almost ruined DXing. In most cases you can't go too far wrong by getting someone new.

INFLATION AND SUCH

Those few really brainwashed ARRLers who fell for the "more is less" baloney last year and believed that a bigger *QST* would cost less are having to face up to the facts of life . . . which are just as I predicted in *73*. *QST*'s costs have gone up substantially . . . and so have the costs of all the other ham magazines . . . the result of the new size. Well, the new size is here and it isn't going back again. Most of the magazines have had to change printers in order to match the new size to bigger presses.

QST has announced their new advertising rates . . . up to $912 for a page now. *73*'s rates are $1095 for one page. The latest rate we have for *HR* is $695, and *CQ* is $575. Since advertising rates are based largely on circulation, this may tell you something.

Apparently the recent rise in *73* readership has some people worried. ARRL is running a poll of their members to find out what it is about *QST* that they don't like. If you get one, please don't forget to tell 'em how much you really enjoy and look forward to the SCM reports and contest results . . . okay?

The 1976 cover price for the ham magazines has been $1 for all but *73* . . . which at $1.50 has been the best selling by far on newsstands and over radio store counters. We understand *QST* is increasing to $1.50 in January . . . no word on *HR* or *CQ*. *73* will go up to $2 in January and the yearly subscription rate will go up to $12.50, with $25 the price for three years. You say you forgot to send in the $17.76? That's the way it goes.

LIFE ON TIME PAYMENTS

A life subscription costs $150 these days. That's a little heavy for most people, so we'll go along with a five payment system . . . $30 per payment for five months. The life subscription is a good deal . . . not a few *73* subscribers bought in years ago and have been sailing free for a long time. You know that inflation is not going to stop . . . that paper and postage are going to keep going up . . . so grab this bargain while you can. Just send $30 and a note that you want to be a lifer.

RECENT HAMFESTS

Let's see . . . somehow we managed to survive an ARRL convention in Philadelphia . . . right in the middle of the American Legionnaires who were dropping like flies. Our *73* booth was constantly surrounded by them all weekend. Few hams had to worry about getting sick, since they stayed away from the convention by the tens of thousands.

The Boston convention pulled about what I expected for a downtown Boston affair . . . not very much. I was on the speaking program

. . . 5:00 am on Sunday morning, I think it was. Well, shucks, that's better than not being able to speak . . . right? I wasn't all that interesting, but if you would like to hear me you can get a tape of the debacle from *73* for $4. An hour, about.

One exhibitor made the mistake of parking his van on a Boston street and had the roof almost pulled out, along with the CB and ham rigs attached to it.

The most popular exhibits, again, were the computer-oriented ones by The Computer Store, Computer Mart, and American Used Computers. I'd sure like to see more combination hamfests/computerfests . . . perhaps with the hamfest part centered on Saturday and the computerfest on Sunday . . . I think it would be good for both groups . . . as well as the about 33% overlap between them.

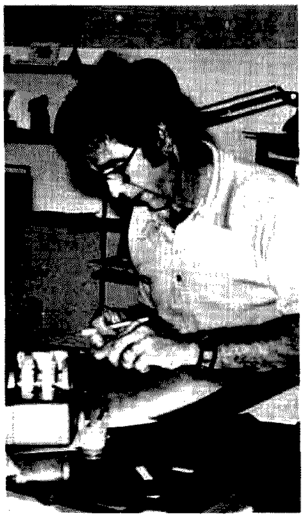
One week after the New England ARRL convention came Expo 76 at Chicago. This affair is improving every year. There is talk of moving it to a hotel near O'Hare next year. Expo had me on the program . . . in prime time, by golly. I didn't have that much different to say from Boston, so there's no good reason to make tapes available of this. I talked a lot about *Kilobyte*, as a matter of fact . . . and we took a lot of *Kilobyte* subscriptions at our booth. I guess just about everyone is getting *73* by now.

While I enjoy getting out and saying hello to a thousand or so readers, I wonder whether I'm doing better that way than staying at home and answering the mail . . . and there is an awful lot piling up as a result of my traveling around. I dunno.

SUPPORTING CAST: II

As promised, here is the second installment of portraits from the *73* gallery.

Chris Dillon is seen here working on file records of orders for books, tapes, and back issues sent out. Every now and then something gets screwed up in shipment and she has to be able to go back and find what was shipped where and when.



Noel Ray Self is working on negatives for 73 Magazine and for the latest 73 books. Photographs have to be made separately and glued onto the negative of the type and drawings . . . a job requiring great precision. Negatives are never perfect, so Ray has to find all pin holes and go over them with paint to opaque them. Where ads are placed on pages, negatives have to be spliced together. Duplicates are then made on single sheets of film. Ray does the splicing . . . also adding the page numbers at the bottom . . . etc.

Continued on page 208

STATEMENT OF OWNERSHIP, MANAGEMENT AND CIRCULATION (Required by 39 U.S.C. 3685). 1. Title of publication, 73 Magazine. 2. Date of filing, 15 Sept 1976. 3. Frequency of issue, Monthly. A. No. of issues published annually, 12. B. Annual subscription price, $10.00. 4. Location of known office of publication (Street, City, County, State and ZIP Code) (Not printers), Pine Street, Peterborough, Hillsboro County, N.H. 03458. 5. Location of the headquarters or general business offices of the publishers (Not printers), Pine Street, Peterborough, Hillsboro County, N.H. 03458. 6. Names and complete addresses of publisher, editor, and managing editor. Publisher (Name and Address) Wayne Green, Peterborough, N.H. 03458. Editor (Name and Address) Wayne Green, Peterborough, N.H. 03458. Managing Editor (Name and Address) Jack Burnett, Peterborough, N.H. 03458. 7. Owner (If owned by a corporation, its name and address must be stated and also immediately thereunder the names and addresses of stockholders owning or holding 1 percent or more of total amount of stock. If not owned by a corporation, the names and addresses of the individual owners must be given. If owned by a partnership or other unincorporated firm, its name and address, as well as that of each individual must be given.) Name, 73 Inc., Peterborough, N.H. 03458. Wayne Green, Peterborough, N.H. 03458. 8. Known bondholders, mortgagees, and other security holders owning or holding 1 percent or more of total amount of bonds, mortgages or other securities (If there are none, so state) Name, none. 9. For completion by nonprofit organizations authorized to mail at special rates (Section 132.122, PSM) The purpose, function, and nonprofit status of this organization and the exempt status for Federal income tax purposes (Check one) Not applicable. 10. Extent and nature of circulation. (X) Average No. copies each issue during preceding 12 months. (Y) Actual No. copies of single issue published nearest to filing date. A. Total No. copies printed (Net Press Run) (X) 96,584 (Y) 98,492. B. Paid circulation 1. Sales through dealers and carriers, street vendors and counter sales, none. 2. Mail subscriptions (X) 90,721 (Y) 92,514. C. Total paid circulation (Sum of 10B1 and 10B2) (X) 90,721 (Y) 92,514. D. Free distribution by mail, carrier or other means samples, complimentary, and other free copies (X) 1,680 (Y) 1,713. E. Total distribution (Sum of C and D) (X) 92,401 (Y) 94,227. F. Copies not distributed 1. Office use, left over, unaccounted, spoiled after printing (X) 3,806 (Y) 3,881. 2. Returns from news agents (X) 377 (Y) 384. G. Total (Sum of E, F1 and 2 — should equal net press run shown in A) (X) 96,584 (Y) 98,492. 11. I certify that the statements made by me above are correct and complete. Signature and title of editor, publisher, business manager, or owner. Biff Mahoney, Business Manager.

STOLEN: Drake TR-22 2 meter transceiver, s/n 640139, beige Trimline TT Handset, magnet mount quarter wave antennae. Crystals for 52/52, 16/76, 37/97, 87/27, 63/03, 34/94. Stolen from Rick Simpson KØUZP, 2723 Rigel Drive, Colorado Springs CO 80906, 303-471-2059.

TAKEN: Wilson T1402 S/M 2 meter handie-talkie, s/n OR6427. Crystals for 52/52, 22/82, 25/85, 16/76, 34/94, 69/09. Stolen from James Hettle, PSC #1, PO Box 2493, Peterson AFB CO 80914.

RIFLED: Heathkit HW-202 with installed Tone Burst Encoder, TTPAD, six (6) sets xtals 34/94, 94/ , 25/85, 115/715, 28/88, 16/76 (switch indicates 04/64 but xtals are

16/76). My ssn 125-32-5960 on various parts internally including underside of trans and rec boards. Also stolen: Courier Comet 23 CB, s/n 12300643. Stolen from my parked auto in Garden City NY on August 30, 1976. If found, please contact heart-broken owner, David K. Gordon WB2YUJ, 155 Nimbus Road, Holbrook, NY 11741.

ROBBED: Yaesu FR-101SD1G HF digital receiver, s/n 6C31339. Yaesu FL101 HF digital transmitter, s/n GE306276. Stolen from Associated Electronic Service, 404 Arrawana, Colorado Springs CO 80909.

RIPPED OFF: Kyokuto FM-144 2m transceiver, s/n 6215. Stolen from vehicle at Los Angeles Coliseum on July 24, 1976. Contact Abel J. Tapia WA6FSZ, PO Box 414, Montclair CA 91763.

RUSTLED: Drake MN-2000 matching network, s/n 6485. Heath SB-650 frequency counter. Stolen on August 29, 1976 from auto in Rockland County. Please contact Cliff Cooley, Jr. WN2GHL, 4 Camp Hill Road, Pomona NY 10970.

HIJACKED: Icom 230 2 meter radio, s/n 240-2915, forcibly removed from vehicle in Fort Wayne, Indiana on September 4, 1976. Report filed with Fort Wayne police. Kenneth C. DeGroff WB9OCW, 62322 Oak Road, South Bend, Indiana 46614

FCC

FCC ANNOUNCES CHANGE IN ISSUANCE OF NOVICE CLASS AMATEUR RADIO CALLSIGNS

As part of its continuing effort to provide the public with rapid and effective service, the Commission will shortly cease issuing distinctive callsigns to Novice class amateur radio stations.

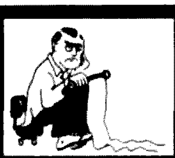
Presently, Novice class stations in the continental United States are issued callsigns prefixed by the letters "WN" to facilitate their identification as Novice stations. Novice stations outside the continental United States are also assigned distinctive callsigns. This practice has proved to be unsatisfactory, however. It has caused several difficulties in the processing of amateur applications, not the least of which are the issuance of the same callsign to two different stations and the issuance of callsigns in callsign blocks, such as "WC," which are not available for general amateur use.

Accordingly, beginning October 1, 1976, each Novice callsign was assigned in accordance with the following:

Present Prefix	*New Prefix*
WNØ	WBØ*
WN1	WB1
WN2	WD2
WN3	WB3
WN4	WD4
WN5	WB5*
WN6	WD6
WN7	WB7
WN8	WD8
WN9	WB9*
WH6	KH6
WL7	KL7
WP4	KP4
WP6	KP6
WG6	KG6
WS4	KS4
WS6	KS6
WV4	KV4
WW6	KW6
WJ6	KJ6

*Callsigns in these areas are presently nearing the end of the WB series. After "WB" prefixes are depleted, "WD" callsigns will be issued.

All amateur Novices with license expiration dates of October 1, 1976 or later will be issued new Novice licenses in the near future. Such new licenses will be identical to the licenses superseded, except that they will have printed on them the callsigns the Novice licensees would have been assigned under the old callsign assignment system upon obtaining higher class operating privileges. The new callsign must be used by the Novice licensee as his callsign.



...de W2NSD/1

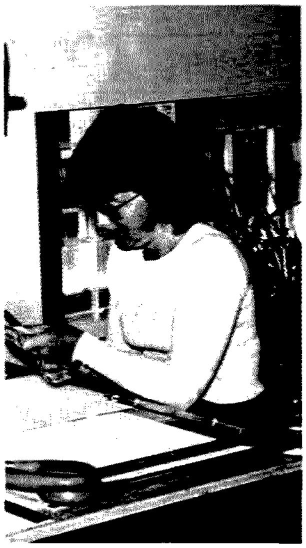
NEVER SAY DIE

EDITORIAL BY WAYNE GREEN

from page 178

Meet Fran Dillon, who handles invoicing for subscriptions and orders for books, tapes and such items. As more and more of this routine is taken over by the slowly expanding computer system at 73, Fran should be able to devote more time to expanding the Radio Bookshop service. Fran also helps with sales and inventory records, a necessary part of keeping things moving smoothly.

Susan Mikula helps with bundling the piles of mail that get sent out every day. Note the mail trays behind her. Mail for each zip code center has to be sorted out and bundled.



Virginia Mammone helps with the pasteup of type to make up the pages of articles in the magazine. This is very exacting work, for each block of type must be set in precisely right . . . if it is off even a hair it looks crooked to the eye on the pages. Once the pages are pasted up, they are made into negatives and printing plates are made from the negatives.

Here's Richard Force WB2QYV/1, who's editing and organizing the new books which are coming from 73 . . . and there are a lot of them in the works, such as three more test equipment handbooks . . . a new Novice Study Guide . . . a new Repeater Atlas . . . General Class Study Guide . . . RTTY Handbook . . . and many more.
